ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road.—This hospital was established 100 years ago, and has been from time to time enlarged by the addition of a very complete out-patients' department, and also by the erection of a new wing, which provides accommodation for 80 in-patients.

THROAT AND EAR HOSPITALS.

METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL.—This hospital was founded in 1838, and is situated in Fitzroy Square. The out-patient department is opened daily at 2.30 p.m. to practitioners and students desirous of acquiring clinical instruction and technical knowledge. Operations are performed on in-patients

on Tuesdays, Wednesdays, Thursdays and Fridays at 10 a.m. Fee for one month's attendance at the hospital one guinea, and for three months two guineas.

HOSPITAL FOR DISEASES OF THE THROAT, Golden Square, W.—This hospital contains 60 beds. Clinical instruction is given daily in the Out-patient Department on diseases of the nose, throat, and ear, and systematic courses of lectures are given during the winter session. There are nine clinics weekly, and an annual out-patient attendance of nearly 60,000. Major and minor operations daily (Mondays excepted) in different theatres. Thirty-six junior clinical assistants are appointed from among the students to assist the surgeons. Students are admitted to the practice of the hospital at the following fees:—Three months, £5 5s.; six months, £7 7s.; longer periods, £10 10s. Further details can be had by applying to the Hon. Med. Secretary.

CENTRAL LONDON THROAT AND EAR HOSPITAL.—This hospital contains accommodation for 26 in-patients. It has a very extensive out-patient department (over 50,000 attendances yearly), which is open daily to all medical practitioners and students, for the purpose of clinical demonstration and instruction. Courses of practical teaching are held twice weekly by members of the staff, which are open to qualified practitioners and advanced students. Each course is of about seven weeks' duration, and includes hospital attendance for that period.

Operations are performed daily (Saturday excepted) at 2 p.m. Special attention is devoted to scientific work in the newly - equipped laboratory. Full particulars will be supplied on application to the Dean.

WOMEN AND CHILDREN.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, Bloomsbury, and Cromwell House, Highgate. This is the largest Children's Hospital in the United Kingdom, and contains 240 beds.

The practice of the Hospital is open to qualified medical men, and to students who have completed four years of medical study, the Hospital having been recognised by the Conjoint Board of England as a place where six months of the fifth year may be spent in clinical work. There are special ophthalmic, aural, dental, and electrical departments. There is also a Museum and Library in connection with the School. Lectures are given every Thursday afternoon during session by members of the staff, and certificates are granted.—Fee for three months' attendance, £5 5s.; perpetual, £10 10s.; £1 1s. for students satisfactorily undertaking clinical clerkships for not less than three months. For tickets and further information, apply to the Secretary, by letter, or by calling at the Hospital.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone Road, N.W.—Qualified medical practitioners and medical students are admitted to the practice of this hospital. Certificates of attendance are recognised by all universities, colleges and licensing bodies. Fee for the course of four weeks, £8 8s. Students are accommodated at the new Residential College (5 Cosway Street) opposite the hospital.

Arrangements have also been made for the preliminary instruction in midwifery now required by the General Medical Council. This will include:—(1) Practical instruction in the methods of examination of pregnant women; (2) delivery of women in labour under the direct supervision of a medical officer of the hospital; (3) practical instruction in the treatment of the mother and child during the puerperium, including clinics held four times weekly by the visiting medical staff. Fee for this special course will be £5 5s. per month.

EAST LONDON HOSPITAL FOR CHILDREN.—This institution was founded about sixty years ago in one of the poorest quarters of the East End of London, and contains 120 beds, with special departments for electric treatment, ophthalmic and dental surgery, etc.

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN.—This important institution, situated in South London, has been rebuilt and appointed on completely modern lines, and now provides 90 beds.

THE SAMARITAN FREE HOSPITAL FOR WOMEN, Marylebone Road, N.W., has 56 beds, and offers excellent opportunities to qualified medical men for clinical study and training in the details of operative gynaecology. Fee: Three months, £3 3s. The success of the staff in this department has gained for them a European reputation. There are 51 beds.

THE HOSPITAL FOR WOMEN, Soho Square.—The hospital contains 67 beds. In connection with this institution there is now an organised school of gynaecology open to qualified medical men and to students after their third year. Clinical assistants to the physicians and surgeons in the in-patient and out-patient departments are appointed every three months. Fee for the three months' course, and certificate, £8 8s.

CHELSEA HOSPITAL FOR WOMEN, FULHAM.—This institution contains 50 beds, and is served by a staff of considerable eminence. In connection with it there is a Convalescent Home at St. Leonards, in which 22 additional beds are at the disposal of the authorities.

EYE HOSPITALS.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, adjoins Charing Cross Hospital in King William Street. It has about 40 beds and a very large out-patient *clinique*. The lectures and demonstrations are arranged with special reference to the requirements of practitioners and senior students. Fee, six months, £3 3s.; perpetual, £5 5s.

ROYAL LONDON OPHTHALMIC HOSPITAL, formerly in Moorfields, and recently rebuilt in the City Road, is the largest hospital devoted to this specialty in Great Britain, and contains 138 beds. Students and practitioners are admitted to the practice daily at 9 o'clock. Operations, 10 o'clock and after. Fee for six months, £3 3s.; perpetual, £5 5s. Further particulars of the Secretary.

ROYAL EYE HOSPITAL, St. George's Circus, South wark.—There are 40 beds and two cots. Fees, £2 2s. for three months, £3 3s. for six months, and £5 5s. perpetual. Courses are held on ophthalmoscopy, refraction, and diseases of the eye; fee, £1 1s. for each course, but perpetual students may attend each course once without extra fee. Pathology class, £1 1s. extra to cover cost of materials.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—This hospital is situated in the Gray's Inn Road, has 26 beds and a large out-patient *clinique*. The post of clinical assistant is open to both men and women, who must be duly qualified and registered practitioners. During the winter session commencing in October lectures and demonstrations are given in all the branches of ophthalmology.

SKIN HOSPITALS.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.—Out-patient department, Leicester Square; In-patient department, Uxbridge Road, W. This hospital has a well-equipped in-patient department, with 40 beds. It has a School of Dermatology at 49 Leicester Square, which is conducted by the medical staff of the hospital. During the past year the free course of Chesterfield Lectures have been well attended. The Out-patient Department has recently been rebuilt at a cost of £10,000, and contains a spacious laboratory and special electrical department which can be seen in operation every afternoon except Saturday. Clinical demonstrations are given every day at 2 p.m., on Selected Cases.

THE WESTERN SKIN HOSPITAL.—This is one of the oldest institutions of the kind in the metropolis, and was started as long ago as 1851. It has recently been removed to larger premises in the Hampstead Road, and the practice of the hospital is open to students and practitioners, who have the opportunity of seeing daily a large number of out-patients. Applications should be made to the Secretary, 17A, Great Portland Street, W.

THE HOSPITAL FOR DISEASES OF THE SKIN, Stamford Street, Blackfriars.—This was the first hospital to be established for the treatment of cutaneous disorders in London. It has an extensive out-patient department, which is open to qualified practitioners. The hospital is shortly to be rebuilt.

METROPOLITAN POST-GRADUATE INSTITUTIONS.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.—This institution affords to medical practitioners special facilities for acquiring technical skill and advancing their medical and scientific knowledge. The building, which is large and commodious, is situated in Chenies Street, Gower Street, and contains lecture and consulting rooms, pathological and clinical laboratories, Röntgen ray room, an ophthalmoscope room, a library and museum, and reading and smoking rooms. *Cliniques*, at which patients are shown, are given every day of the week except Saturday, at 4 p.m. Lectures on Medicine, Surgery, and other allied subjects are delivered on Mondays, Tuesdays, Wednesdays, and Thursdays at 5.15 p.m. Four sessions of practical classes, each lasting six weeks, and two vacation sessions each of three weeks' duration, are held during the year, the subjects taught comprising anaesthetics, clinical examination of nervous system, clinical microscopy, clinical methods and physical diagnosis, clinical examination of stomach contents, cystoscopy, electro-therapeutics, gynaecology, intestinal surgery, laryngology, massage and medical electricity, ophthalmology, otology, orthopaedics, rhinology, Röntgen rays, sigmoidoscopy, surgical anatomy and diagnosis. There are, in addition, extra-mural classes in operative surgery and practical anatomy with dissecting. Special tutorial classes in medicine, surgery, midwifery, and pathology for gentlemen reading for the higher qualifications have recently been instituted, and are conducted regularly throughout the year. The annual subscription for medical practitioners of either sex is One Guinea. Full information may be obtained from the medical superintendent, 22 Chenies Street, Gower Street, W.C.

WEST LONDON POST-GRADUATE COLLEGE.—The West London Hospital, Hammersmith Road, W., contains 160 beds; the post-graduate course was started in 1895, and this is the original post-graduate college in London attached to a general hospital. Instruction is given in the out-patient department daily at 2.15 p.m. by the assistant physicians and assistant surgeons. The physicians and surgeons attend daily at 2.30 p.m., when post-graduates can accompany them in their visits to the wards. Operations are performed daily at 2.30 p.m. Demonstrations are held every morning and there are lectures every evening at 5 p.m. (Saturdays excepted). Special classes are held in bacteriology, vaccine therapy, diseases of the eye, throat, X-rays, anaesthetics, intestinal surgery, tropical medicine, cystoscopy, venereal disease, operative surgery, &c.

Fees.—The fee for the hospital practice, including all the ordinary lectures and demonstrations, is £1 1s. for one week; £3 3s. for one month; £6 6s. for three months; £10 10s. for six months; £15 15s. for one year, and £30 for a life ticket. A course of attendance on either the medical or surgical practice alone may be taken out for the fee of £4 4s. for three months. The fee for three months' attendance in any one special department, other than medicine or surgery, is £3 3s. A prospectus containing full particulars will be forwarded on application to Mr. D. Armour, Vice Dean.

NORTH-EAST LONDON POST-GRADUATE COLLEGE.—This post-graduate school is established in connection with the Prince of Wales's General Hospital, Tottenham, N., which is recognised by the University of London as a place of post-graduate study for the M.D. and M.S. degrees, and by the Admiralty and the India Office for purposes of study leave. Facilities are here afforded to qualified medical practitioners for taking part in the work of an active general hospital, and for attending demonstrations

in various branches of medicine, surgery, and gynaecology, with opportunities for clinical instruction in diseases of the eye, ear, throat, nose, skin, in fevers, psychological medicine, the administration of anaesthetics, radiography and dentistry. Cliniques, lectures and demonstrations are given by members of the teaching staff in the lecture room, in the wards, in the various out-patient departments, and in certain affiliated institutions. Operations are performed every afternoon of the week, except Saturday. Special classes, the attendance at which is limited, are arranged in gynaecology, the surgical diseases of children, including orthopaedic surgery, diseases of the throat, nose and ear, diagnosis of diseases of the nervous system, ophthalmoscopy and refraction, clinical pathology, diseases of the skin, abdominal surgery, radiography, bacteriology (which is accepted by the University of Cambridge for the D.P.H. diploma) vaccine therapy, pathological chemistry and medical electricity. The fee for a three months' course of study, which may be begun at any time, in any single department, is one guinea. A fee of three guineas admits to the whole practice of the hospital for a similar term (one month, 2 guineas), and a perpetual ticket for the practice of the hospital may be obtained on payment of a fee of 10 guineas. A vacation course will be held during the latter half of September, beginning on the 16th inst., the fee for which is 2 guineas. The opening lecture of the Winter Session will be given by Sir Almon Wright towards the end of October. Additional information with a syllabus of lectures, demonstrations, and special classes, may be obtained from the Dean of the Post-Graduate College, Dr. A. J. Whiting, at the Hospital, or at 142, Harley Street, W.

LONDON POST-GRADUATE ASSOCIATION.—This Association offers facilities for Clinical Study to qualified medical men. Joint cards of admission are issued to the Clinical Instruction of the following General Hospitals and Schools of Medicine:—Charing Cross, Guy's, King's College, St. George's, St. Mary's, St. Thomas's, University College, Westminster, beside several special hospitals. *Fee.*—For three months, 10 guineas; for six months, 15 guineas; and for any longer period at the further rate of 9 guineas for each additional six months. Further particulars may be obtained of the Secretary, London Post-Graduate Association, 20, Hanover Square, London, W.

THE LONDON SCHOOL OF CLINICAL MEDICINE is entirely reserved for qualified practitioners, no unqualified students being allowed to attend its clinics and classes. The school is held at the Seamen's Hospital, Greenwich, with which are affiliated for teaching purposes the Royal Waterloo Hospital for Children and Women, the Bethlem Hospital, and the General Lying-In Hospital, all within the South-Eastern district. The Dreadnought Hospital is situated at Greenwich, and contains 250 beds, which are continually occupied by patients suffering from every variety of disease. It provides annually for 2,000 in-patients and 19,000 out-patients. The out-patient department at the Dreadnought Hospital is supplemented by the Society's dispensaries in the East India Dock Road, and at Gravesend, at which the present annual attendance is approximately 4,000 patients. The hospital is easily reached from London:—(a) By train from Charing Cross or Cannon Street to Greenwich Station, which is within five minutes' of the hospital. (b) By train from Charing Cross or Cannon Street, or from District and Metropolitan Stations to New Cross, and thence by electric tram (seven minutes). Out-patient clinics are held in surgery, medicine, and the special departments every morning; whilst in the afternoons ward clinics are given in medicine, in surgery, and in one of the special departments. Operations are performed daily. The fee for attendance on the ordinary practice of the hospital provides for admission to the wards, operating-theatres, post-mortem rooms, out-patient rooms, and clinics. Most of the practical clinical classes, such as those in laryngology, ophthalmology and dermatology are included in the fee for Clinical Teaching,

but may be omitted if desired. Other practical classes, such as operative surgery and pathology, are arranged each session.

The following are some of the principal provincial hospitals having the greatest number of beds, to which students are admitted, where clinical instruction can be obtained, but to which there is no medical school attached:—

ROYAL BERKSHIRE HOSPITAL.—The town of Reading, in which this hospital is situated, has a very large working-class population, and excellent opportunities for clinical instruction in the wards and extensive out-patient department are afforded here. This hospital, which contains 188 beds, has been recently enlarged, and there is also a splendid library, in which the Reading Pathological Society holds its meetings.

BRADFORD INFIRMARY.—The hospital contains 210 beds. Non-resident pupils are received and abundance of clinical material is obtainable in all the special departments of Medicine and Surgery. One year's attendance is recognised by the Examining Boards. Fee, perpetual, £10 10s.

ROYAL DEVON AND EXETER HOSPITAL, Exeter.—This hospital contains 200 beds (including special children's wards), and numbers on its staff several well-known names; has a good library. Attendance on the practice of this hospital qualifies for all the examining boards, and students can attend Midwifery on application to the House Surgeon. Arrangements may also be made by which practitioners may have the use of the museum and library, and other facilities.

LEICESTER INFIRMARY is duly recognised by the various examining bodies, and contains 230 beds, and at the Children's Hospital in connection, 42. A new wing containing 100 beds has recently been added, together with a new Nurses' Home.

LIVERPOOL.—The principal hospitals in this city, four in number, now form a combination for teaching purposes, in connection with the Liverpool University. These are referred to in another column, under "Universities," and are the Liverpool Northern Hospital, the Royal Southern Hospital, the Royal Infirmary, the Stanley Hospital, together with five special hospitals, the whole containing a total of 1,127 beds.

THE LIVERPOOL SKIN HOSPITAL AND EXTRA-MURAL SCHOOL OF DERMATOLOGY, in Pembroke Place, has eight beds and an Out-patient Department where over two thousand different patients are registered annually, and is open to Senior Students and Practitioners of Medicine. There is an excellently equipped "Light" Department where instruction is given in X-Ray and Finsen Light Therapy, and attached to the Hospital is a Museum of Dermatology. Terms for private instruction, 10 guineas per month. Dr. Stopford Taylor will give a course of twelve demonstrations, commencing to-day (September 14th). Fee for the course, 1½ guineas.

NORFOLK AND NORWICH HOSPITAL.—This hospital is recognised by the Colleges, and contains 230 beds. Fees, £10 10s. for six months, £15 15s. for twelve months' medical and surgical practice. Pupils, resident and non-resident, are admitted.

NORTH STAFFORDSHIRE INFIRMARY, Hartshill, Stoke-on-Trent.—This institution is built on the pavilion plan, and has accommodation for 216 patients, including children's wards, women's wards, and a special department for the treatment of diseases of the eye, so that there are excellent facilities here for acquiring a practical knowledge of the profession.

NOTTINGHAM GENERAL HOSPITAL.—As a large commercial and industrial centre, Nottingham boasts of a large general hospital and several special institutions. The General Hospital contains 254 beds, and is staffed by several well-known physicians and surgeons. The practice is open to qualified members of the profession, and house appointments obtained hereat yield valuable material for study, especially in the direction of accidental injuries.

THE ROYAL SUSSEX COUNTY HOSPITAL, BRIGHTON.—This hospital possesses about 196 beds, as well as a

large out-patient department, and a well-appointed clinical research and bacteriological department. Hospital practice may be gained here for a period not exceeding two years on payment in advance of a fee of 20 guineas. There is also an excellent library attached.

WOLVERHAMPTON AND STAFFORDSHIRE HOSPITAL.—This is one of the largest hospitals in the Midlands, and contains 212 beds. Situated as it is in the centre of the great coal and iron industries, it affords ample material for clinical study, and as the Hospital is recognised by the Royal Colleges, and has an excellent staff, its position is excellent.

Ireland.

THE IRISH MEDICAL SYSTEM.

THE system of medical teaching in Ireland differs from that in England in important particulars. In London each clinical hospital has its attached medical school, fully equipped, which educates the students of that hospital and very seldom those of any other. In Dublin, on the contrary, the hospitals and schools are entirely separate (except that Sir Patrick Dunn's Hospital is officially connected with Trinity College), and a student of any school is free to enter for the whole or any part of his course at any school or hospital he pleases.

COST OF MEDICAL EDUCATION IN IRELAND.

The cost of obtaining a medical qualification depends to some extent on the qualification sought. In this connection the following tables may be of use to the prospective student:—

COST OF MEDICAL EDUCATION.

School of Physic, Dub. Univ. ..	£122 17s.
Royal College of Surgeons School	£124 19s.
University Colleges	About £125.
Queen's University, Belfast ..	£105

COST OF DIPLOMAS OR DEGREES.

Dublin University	£27 (to this must be added £83 4s., the cost of obtaining an Arts degree),
-------------------------	--

National University	£25.
Queen's University, Belfast ..	£19 19s.
Conjoint Royal Colleges	£42.
Apothecaries' Hall	£22 1s.

Thus, the absolute payment will amount to somewhere between £125 and £233 1s. according to the course chosen. For the Conjoint Colleges the entire cost is £166 19s., taking the minimum mode of payment. So that, assuming that extras or voluntary costs are incurred the total will vary, say, from £170 to £200. "Grinding," although not officially recognised, occupies a position similar to that of the extra-mural instruction of other schools. Its cost must be reckoned among the expenses of the course, for, while not essential, it has become customary for almost all students to obtain aid in their studies in this way. As a rule, this private instruction costs about £5 5s. for each of the four examinations.

The above sum, or something like it, may be expended by the student or his parent in paying for lectures, &c., and examination fees as they fall due, and there is no difficulty in obtaining the needful information for his

guidance if he likes to pay for his course in this fashion. All the schools require fees for each course to be paid in advance.

Women are admitted to all the courses, degrees, and licences on the same terms as men.

DATE OF ENTRY.

The entry of names and commencement of study in Ireland is *supposed* to date from the 1st of October in each year, but entries are accepted up to the end of that month, or in some schools even later. It should be remembered that no credit is given for studies or attendance until the entry is regularly made. The student must attend three-fourths of the lectures delivered, and if he loses any time at the beginning he must make up for it afterwards by constant attendance.

The student begins work by attending a recognised medical school each morning at ten o'clock, and occupying his day, to five p.m., between lectures and dissections. His vacations are a fortnight at Christmas and a fortnight at Easter, and the academic year ends at the end of June.

PRELIMINARY EXAMINATIONS.

The first act of the student is to pass a preliminary examination, without which he cannot get credit for any medical studies pursued. The next is to commence medical study. This he does by entering for lectures at a medical school. From the school registrar he gets a form of certificate, and his third act is to take it or send it to the Branch Medical Council, 35 Dawson Street, Dublin, unless, as is usually the case, this duty is undertaken for him by the school registrar. He is thereupon placed upon the Register of Medical Students (without fee), and his period of study counts from that date. He must register at the earliest possible moment, or he may lose credit for his work.

The only preliminary examination held specially for medical students is that held conjointly by the Royal Colleges of Physicians and Surgeons, but other examinations—*e.g.*, the public entrance at Trinity College, the matriculation of the National and Queen's Universities, the Intermediate Examination passes in the required subjects, and certain other examinations recognised by the General Medical Council, are accepted as equivalent.

The subjects of examination as prescribed by the General Medical Council are as follows:—1. English language, including a specified author, dictation, grammar, and composition; also parsing and analysis from a book specified. 2. Latin, including grammar, translation from specified authors, and translation of easy passages not taken from such authors. 3. Elements of mathematics, comprising (a) arithmetic, including vulgar and decimal fractions; (b) algebra, including simple equations; (c) geometry, Euclid, Books I., II., and III., with easy deductions. 4. One of the following optional subjects:—(a) Greek, (b) French, (c) German.

THE IRISH LICENSING BODIES.

The Medical Licensing Bodies of Ireland are five in number, and, as a rule, students will gravitate into one or other of six classes:—*a.* Those who enter Trinity College, and take a full graduation in Arts in addition to their professional degrees. *b.* Those who take the conjoint licence of the Royal Colleges of Physicians and Surgeons. *c.* Those who take their qualifications at the National University of Ireland, where graduation in Arts is not necessary. *d.* Those who enter Queen's University, Belfast, and take their course and degrees there. *e.* Those who take the licence of the Apothecaries' Hall. *f.* Those who pursue their studies in Ireland, but who migrate to London, Edinburgh, or Glasgow for their licences.

We do not attempt to give details as to the requisite courses of instruction for degrees or diplomas, as our epitome must necessarily be insufficient for the information of the student, and we can occupy our available space with information more useful to him. The official information upon which students may depend can be obtained by sending a note to the Registrars of the Licensing Bodies or Schools.

THE UNIVERSITY OF DUBLIN.

The University of Dublin grants the degrees of M.B., B.Ch., and B.A.O. to students who have obtained their B.A. degree, and who have been for at least five academic years on the books of the Medical School, and the higher degrees of M.D., M.Ch., and M.A.O. to graduates of certain standing who hold the degrees of M.B., and B.Ch. It does not grant degrees to any but graduates in Arts, and consequently its degrees hold a high rank, and are sought for by those who look forward to occupying the best positions in the profession.

The expense of obtaining the degrees of M.B., B.Ch., and B.A.O. is approximately as follows:—Lectures, £67 4s. od.; Hospitals, £55 13s.; Degree Fees, £27.—Total, £149 17s. od.

The expense of the B.A. degree, amounting altogether to £83 4s., should be added, making the total cost £233 1s. od.

Diploma in Medicine, Surgery, and Midwifery.—Candidates for the diplomas in Medicine, Surgery, or Obstetric Science must be matriculated in Medicine, and must have completed two years in Arts and five years in medical studies. The medical course and examinations are the same as for the degrees. Fees for the diplomas in medicine, surgery, and midwifery, £21. A diplomate, on completing his course in Arts and proceeding to the degree of B.A., may become a Bachelor of Medicine on paying the degree fees.

In addition to its ordinary qualifications the University grants the following degrees and diplomas:—

Doctor of Medicine.—To obtain this the candidate must have passed the final examinations, and be of M.A. standing. He must then read a thesis before the Regius Professor of Medicine. Fee for this degree, £13.

Master of Surgery.—The candidate must be a Bachelor in Surgery of three years' standing, and must then pass an examination in clinical surgery, operative surgery, surgical pathology, surgery, and surgical anatomy (on the dead subject). Fee for this degree, £11.

Master in Obstetric Science.—The candidate must have passed the M.B. and B.Ch. examinations, and have completed, in addition to the courses for M.B., B.Ch., a course of obstetric medicine and surgery. He is then required to pass an examination in the following subjects:—Practice of midwifery, gynaecology, anatomy of female pelvis and elementary embryology, and clinical gynaecology. Fee for this degree, £5.

Diploma in Public Health.—The candidate must be a Registered Medical Practitioner; must have completed, subsequent to obtaining a registrable qualification, four months' practical instruction in a laboratory in practical work in chemistry and bacteriology applied to public health; he must have studied practically outdoor sanitary work for six months under an approved officer of health; and have attended, after qualification, for three months, the practice of a hospital for infectious diseases.

Degrees in Dental Science.—Candidates for the B.Dent.Sci. degree in dental science must have taken a degree in Arts, and must have had their names in the books of the Medical School for four years. Three examinations must be passed—namely, the Preliminary Scientific at the end of the first year, the Intermediate at the end of the third year, and the Final Dental at the end of the fourth year. The total fees are £280 2s.

QUEEN'S UNIVERSITY, BELFAST.

The Queen's University confers the degrees of M.B., B.Ch., and B.A.O., on students who have followed the prescribed course of studies for five academical years, and passed the prescribed examinations. At least three of the years are spent in attendance on courses at the University. The expense is about £104.

Degrees of M.D., M.Ch., and M.A.O.—These degrees are not conferred until the expiration of at least three academic years, or, in the case of graduates of the University in Arts or Science, of at least two academic years, after admission to the primary degrees in the

Faculty of Medicine. Every candidate must show that in the interval he has pursued such courses of study, or been engaged in such practical work as may be prescribed. These degrees may be conferred by the Senate either (a) after an examination, which includes written, oral, clinical, and practical examinations; or (b) on the submission of a thesis or other evidence of original study or research, to be approved by the Faculty of Medicine, after an oral or other examination of the candidate on the subject thereof. On application for these degrees a fee of £2 2s., and on admission to them a fee of £8 8s., must be paid.

The subjects of the examination for the degree of M.D. are:—The Principles and Practice of Medicine, and one other special subject to be selected by the candidate from: (i.) Human Anatomy, including Embryology; (ii.) Physiology; (iii.) Pathology; (iv.) Pharmacology and Therapeutics; (v.) Sanitary Science and Public Health; (vi.) Forensic Medicine and Toxicology; (vii.) Mental Diseases.

The subjects of the examination for the degree of M.Ch. are:—(1) Surgery, Theoretical and Practical, including Ophthalmology and Otolaryngology. (2) Surgical Pathology. (3) Surgical Anatomy and Operative Surgery, with the use of surgical instruments and appliances.

The subjects of the examination for the degree of M.A.O. are:—(1) Midwifery. (2) Diseases of Women and Children. (3) Pathology in its special bearing on Midwifery, and Diseases of Women and Children.

Diploma in Public Health.—This diploma is given after examination to registered medical men, on similar conditions to those obtaining elsewhere.

NATIONAL UNIVERSITY OF IRELAND.

THE National University of Ireland confers the degrees of M.B., B.Ch., and B.A.O., on students who have followed the prescribed course for five academic years, and passed the prescribed examinations. At least three years must be spent at one of the constituent colleges of the University, viz., the University Colleges at Dublin, Cork, and Galway. The University also confers the higher degrees of M.D., M.Ch., M.A.O., B.Sc. (Public Health), D.Sc. (Public Health), B.D.S., and M.D.S.

The expense of obtaining the degrees of M.B., B.Ch., and B.A.O., is approximately:—Lectures, £68 5s.; Hospitals, £56 14s.; University Fees, £19. Total, £143 19s.

The conditions for the higher degrees are:—

Doctor in Medicine.—Candidates may present themselves for the examination for this degree after an interval of three academical years from the time of obtaining the M.B., B.Ch., B.A.O. degrees; but in the case of candidates who have obtained a degree of the University in the Faculty of Arts, an interval of two academical years is sufficient.

Candidates must at the same time produce a certificate of having been, for at least two academical years, engaged in hospital or private medical, surgical, or obstetrical practice respectively, or in the military or naval medical service.

Candidates at this examination must answer in Medicine and Pathology.

The examination in each subject consists of:—

- (a.) A Written Examination.
- (b.) An Oral Examination.

In addition every candidate must diagnose at the bedside at least three medical cases, and prescribe treatment. He must also write detailed reports on at least two cases, to be selected by the examiners, and discuss the questions arising thereon. Fee, £10.

Master in Surgery.—The following are the subjects of examination:—

Surgery, theoretical and practical, including Ophthalmology and Otolaryngology; Surgical Pathology; Surgical Anatomy and Operative Surgery, with the use of Surgical Instruments and Appliances.

The other conditions are the same as for the M.D. degree. Fee, £10.

Master in Obstetrics.—Academic standing is as for the two previous degrees.

Each candidate must furnish satisfactory evidence

that since graduating in medicine he has (1) had personal charge of at least *twenty* cases of labour; and (2) attended during a period of three months the practice of a clinical hospital for diseases of women, where at least six beds are in constant occupation, or in a special ward of a general hospital, where such cases only are treated, and containing at least six beds in constant occupation.

Candidates at this Examination must answer in the following subjects:—Midwifery, Diseases of Women and Children, Pathology, the Use of Instruments and Appliances. The Examination in each subject consists of—(a) an Oral Examination, with practical illustrations, including use of instruments and appliances; (b) a written Examination; (c) a clinical Examination, as far as practicable. Fee, £10.

Bachelor of Science, Public Health.—A candidate shall not be admitted to receive the Degree of Bachelor of Science, Public Health, unless he—(a) shall have received the Degrees of M.B., B.Ch., and B.A.O. at least one year previously; (b) shall have pursued an approved course of study in the Faculty of Medicine; and (c) shall have passed the prescribed examination. Fee, £7.

Courses.—In addition to D.P.H. Course:—(1) Special Pathology (three months). (2) Bacteriology, second course (three months). (3) Advanced Course in Hygiene (three months).

Doctor of Science, Public Health.—The regulations are not yet published. Fee, £10.

Diploma in Public Health.—This Diploma may be granted to matriculated students of the University who shall have completed courses of study, approved for the purpose, and shall have passed the prescribed examinations: provided that it shall not be granted except to a registered medical practitioner.

The conditions and examination are similar to those already quoted for the University of Dublin.

Degrees in Dentistry.—Candidates for the Degree of B.D.S. shall be required to pass, after matriculation, four University Examinations, namely:—A First University Examination in Medicine, as for medical students; a Second University Examination in Medicine, as for medical students; an Intermediate University Examination in Dental Surgery; a Final Examination for the Degree of B.D.S.

Students must follow a definite course of instruction, and must be, for at least two years, apprenticed to a registered dentist.

The regulations for the degree of M.D.S. are not yet published.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.

Examinations are held conjointly by the two Colleges. The course, as in other bodies, extends over five years, with examinations at the end of the first, second, third, and final years. These examinations are conducted by examiners chosen by each of the Colleges for the subjects appropriate to them. The curriculum has recently been revised, and made of a more practical nature. As in the English Colleges, the subjects of the First Professional Examination may be studied either at a medical school or at an institution other than a medical school which is recognised by the Colleges, after due inspection, for instruction in these subjects. We recommend students to apply for the official programme to the Secretary of the Committee of Management, Royal College of Surgeons, or to the Registrar of either College. In the case of the Preliminary Examination seven clear days' notice must be given to the Secretary; fourteen days' notice is required from candidates for the Professional Examinations.

The total of the examination fees, spread over the four examinations, is £42, while the school and hospital fees, if taken in Dublin, amount to £124 19s., making altogether £166 19s., exclusive of re-examination fees, which have to be paid in case the candidate fails to pass his examination.

The Colleges also confer a Diploma in Public Health, of which information will be found on page liii.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

This College issues a Licence in Medicine and a Licence in Midwifery to registered medical practitioners.

Licence in Medicine.—The subjects of examination are:—Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene and Therapeutics.

Licence in Midwifery.—The subjects of examination are:—Gynæcology and Midwifery. A Registered Medical Practitioner of five years' standing is exempted from the examination by printed questions.

Fees.—Fee for the Licence to Practise Medicine, £15 15s. Fee for the Licence to Practise Midwifery, £5 5s.

Membership.—The Membership is open to University Graduates in Medicine and to Licentiates of the Royal Colleges of Physicians of the United Kingdom. The Examinations for Membership are held in January, April, July, and October, and such other times as the President may appoint. Fee to Licentiates of the College, £21, to others £36 15s.

Fellowship.—Fellows are elected from among the members of at least one year's standing. Fee £60.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

This College grants a Licence in Surgery to registered medical practitioners.

The subjects, methods, times, and places of examination are those of the surgical group of the Final Professional Examination of the Conjoint Board in Ireland of the Royal College of Physicians and the Royal College of Surgeons. (See their regulations.) Candidates must pass in all the subjects at one examination. Special examinations will not be granted under any circumstances.

A candidate whose name is entered either on the Medical Register for the United Kingdom, the Colonial Medical Register, or the Foreign Medical Register of the year in which he presents himself for examination, and who satisfies the Council that he has passed through a course of study and examinations equivalent to those required by the regulations of the Conjoint Board of the Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland, preceded by the passing of an examination in Arts recognised by the General Medical Council, may, at the discretion of the Council, be admitted to the examination.

Candidates are required to lodge their applications, declarations, and certificates with the Registrar, at least twenty-one days before the date of the examination.

The fee for examination is for each admission five guineas. Of these fees five guineas will be reckoned as part of the fee payable upon admission to the Licence in Surgery. The fee to be paid upon admission to the Licence in Surgery is twenty-five guineas.

Fees will not be returned under any circumstances. All applications with reference to the examination for the Licence in Surgery should be addressed to the Registrar, Royal College of Surgeons in Ireland, Dublin.

Fellowship.—The examination for the Fellowship is divided into two parts,—viz.: The Primary and the Final. The subjects of the primary examination are—anatomy, including dissections, physiology, and histology. The examination is partly written, partly *viva voce*, and partly practical. Candidates must pass in all the subjects at one examination. The subjects of the final examination are—Surgery, including surgical anatomy, and pathology. The examination is partly written, and partly *viva voce*, and includes the examination of patients, and the performance of operations on the dead body. Candidates must pass in all the subjects at one examination. The examinations are held three times in each year, commencing:—The primary on the first Monday in March, the third Monday in July, and the third Monday in November. The final on the second Monday in March, the third Wednesday in July, and the fourth Monday in November. Special examinations will not be granted under any circumstances.

Candidates are required to lodge their applications, certificates, and receipts for fees with the Registrar, at least seven days before the date of the examination.

Conditions of Admission to the Primary Examination.—A candidate must produce evidence of having completed the examinations in anatomy, physiology, and histology of a university or licensing body whose degrees or licenses entitle the holder to have his or her name placed on the Medical Register of the United Kingdom. A candidate whose name is entered on the Colonial or Foreign Medical Register of the year in which he presents himself for examination, and who satisfies the Council that he has passed through a course of study and examination equivalent to those required by the regulations of the Conjoint Board in Ireland of the Royal College of Physicians and the Royal College of Surgeons, preceded by the passing of an examination in Arts recognised by the General Medical Council, may also, at the discretion of the Council of the College, be admitted to the primary examination for the Fellowship.

Conditions of Admission to the Final Examination.—A candidate must have passed the primary examination, must be a licentiate or graduate in surgery of a university or licensing body recognised by the General Medical Council, and must produce a certificate of general good conduct, signed by two or more Fellows of the College, and evidence that he is not less than twenty-five years of age.

Fees.—1. The fees for examinations are as follows:—Primary examination, each admission, 5 guineas; final examination, each admission, 5 guineas. 2. Of these examination fees ten guineas will be reckoned as part of the fee payable upon admission to the Fellowship. 3. The fee to be paid upon admission to the Fellowship is forty guineas, except when the candidate is a Licentiate of the College, in which case the fee is twenty-five guineas.

All applications with reference to the examinations for the Diploma of Fellow should be addressed to The Registrar, Royal College of Surgeons in Ireland, Dublin.

Licence in Dental Surgery.—Candidates for the licence in Dental Surgery are required to pass two professional examinations. They must have passed a recognised Preliminary Examination in general education, and been registered as medical or dental students by the General Medical Council. They must have been engaged during a period of two years in acquiring a practical familiarity with the details of mechanical dentistry under the instruction of a registered dentist, or under the direction of the superintendent of the mechanical department of a recognised dental hospital where the arrangements for teaching Mechanical Dentistry are satisfactory to the Council of the College. This instruction may be commenced or attended before the Candidate registers as a medical or dental student. They must have been engaged during four years in the acquirement of professional knowledge subsequently to the date of registration as a medical or dental student. One year's *bona fide* apprenticeship with a registered dental practitioner, after being registered as a medical or dental student, may be counted as one of the four years of professional study. They must produce evidence of having followed a prescribed course of study. There are special exemptions in the case of persons already holding a surgical or dental qualification. All applications with reference to the examination for the Diploma in Dental Surgery should be addressed to The Registrar, Royal College of Surgeons in Ireland, Dublin.

APOTHECARIES' HALL OF IRELAND.

The Licence of this Hall is granted to students who present certificates of having fully completed the course of study as laid down in the curriculum, and who pass the necessary examinations. The diploma of the Apothecaries' Hall of Ireland entitles the holder to be registered as a practitioner in medicine, surgery, and midwifery, and possess the privileges of an apothecary.

There are three professional examinations, the total

fees for which amount to thirty guineas. Women are eligible for the diploma.

Registered medical practitioners receive the diploma of the Hall upon passing an examination in the subject or subjects not covered by their previous qualification, and on paying a fee of fifteen guineas.

The fees payable for each examination are as follows : Professional Primary, £5 5s. ; Intermediate, £10 10s. ; Final Examination, £15 15s.

Applications and schedules, together with bank receipt for the fee, must be lodged with the Registrar, Apothecaries' Hall, 40 Mary Street, Dublin, at least fourteen clear days before the day of examination.

Candidates who desire to obtain the Letters Testimonial of the Apothecaries' Hall of Ireland, must, before proceeding to the Final Examination, produce evidence of having attended courses of instruction as follows :

One course each (winter course of six months) of the following : Anatomy (lectures), chemistry (theoretical), midwifery, practice of medicine, physiology and surgery. Dissections, two courses of six months each.

Courses of three months.—Materia medica, medical jurisprudence, chemistry (practical), practical physiology and histology, operative surgery, physics, clinical ophthalmology, biology, clinical instruction in mental disease, pathology, and a course in vaccination.

Medico-Chirurgical Hospital, twenty-seven months to be distributed over the last four years of study. The candidate may substitute for nine months in this hospital attendance six months as a resident pupil.

Three months' study of fever.

Six months' practical midwifery and diseases of women.

Three months' practical pharmacy in a recognised clinical hospital or a recognised school of pharmacy, or a year in the compounding department of a licentiate apothecary or a pharmaceutical chemist.

Each candidate before receiving his diploma must produce evidence that he has attained the age of 21.

Each candidate must produce evidence of having before entering on medical studies passed a preliminary examination in general education.

The details of the course of education required and syllabus of the examinations will be supplied on application to the Registrar at 40, Mary Street, Dublin.

THE DIPLOMA IN PUBLIC HEALTH.

This diploma is granted by Dublin University, the National University, Queen's University, and the Conjoint Royal Colleges. Every candidate must be a registered medical practitioner. The examination is in :—(1) Chemistry (including chemical physics). (2) Engineering and architecture. (3) Sanitary law and vital statistics. (4) Hygiene. (5) Bacteriology. (6) Meteorology. The General Medical Council recommend that all candidates shall have studied in a special bacteriological laboratory, also for six months as pupil of a working medical officer of health, described, for Ireland, as "the medical officer of health of a county or of one or more sanitary districts having a population of not less than 30,000 ; or a medical officer of health who is a teacher in Public Health of a recognised medical school."

THE IRISH MEDICAL SCHOOLS.

The Irish Medical Schools are as follows :—

THE SCHOOL OF PHYSIC OF DUBLIN UNIVERSITY.—

Every student of the school must be matriculated in Medicine, for which a fee of 5s. is payable, but he need not attend any of the Arts course unless he desires to obtain a University licence or degree in medicine, surgery, and midwifery. No student is permitted to matriculate unless he has passed the Entrance Examination of Trinity College, or some other examination recognised by the General Medical Council. Two medical scholarships are given annually at the School of Physic, value £20 per annum, tenable for two years, the examinations for which are held each year in June ; one scholarship is given in anatomy and institutes of medicine ; the other in zoology, chemistry, botany, and experimental physics. A prize of £100 is awarded by the Board to the suc-

cessful candidate at a special examination in alternate years in medicine or in surgery, provided that the merit be deemed sufficient. The successful candidate is required to spend three months in the study of medicine or surgery, as the case may be, in Berlin, Paris, or Vienna. Before he can obtain the first instalment of £50 he must satisfy the Senior Lecturer that he possesses sufficient knowledge of a Continental language to derive full benefit from the prize. The examination is held in June, and is open to students who have passed the Final Examination in Medicine or in Surgery, as the case may be, within two years of the examination.

In order to obtain the second sum of £50 the prizeman must have furnished to the Regius Professor his formal report on the hospitals attended by him within two years from the time of obtaining the prize.

The Sir John Banks Medal and Prize, founded by the late Sir J. Banks, M.D., Regius Professor of Physic, are awarded to the best and second best answers at the Medical Travelling Prize Examination.

The Edward Hallaran Bennett Medal and Prize, founded by pupils of the late Dr. E. H. Bennett, formerly Professor of Surgery, are awarded to the best and second best answers at the Surgical Travelling Prize Examination.

Class prizes are given at the end of the session of between £5 and £10 in value. The John Mallet Purser Medal, founded by Prof. Purser's past pupils, is awarded annually to the student who, at the ordinary June Intermediate Medical Examination, Part I., in Anatomy and Institutes of Medicine, obtains highest marks in Physiology and Histology, provided that he passes the examination in full, and the Cunningham Medal, *in memoriam* of the late Prof. D. J. Cunningham to the student, who, at the same examination, obtains highest marks in Anatomy, passes the examination.

Fitz-Patrick Scholarship.—This scholarship consists of the interest on £1,000. It is awarded annually to the student who obtains the highest aggregate marks at the five sections of the Final Examinations, provided that he has completed his medical course in the prescribed period of five years.

A School of Dental Science has been organised in connection with the School of Physic in Trinity College. Lectures are given in anatomy, chemistry, surgery, physics, physiology and histology, dental mechanics, orthodontia and anæsthetics.

Post-Graduate Classes.—A short post-graduate course is now given annually in September in connection with Trinity College Medical School. It includes special work on Diseases of the Eye, Nose, and Throat, Gynecology, Diseases of the Skin, X-ray work, Medicine, Surgery (clinical and operative), and Clinical Pathology.

THE ROYAL COLLEGE OF SURGEONS IN IRELAND, SCHOOLS OF SURGERY.—These schools are attached by Charter to the Royal College of Surgeons, and have existed as a department of the College for over a century. They are carried on within the College buildings, and are specially subject to the supervision and control of the Council. The buildings have been reconstructed, the capacity of the dissecting room nearly trebled, and special pathological, bacteriological, public health, chemical, and pharmaceutical laboratories fitted with approved appliances, in order that students may have the advantage of modern methods of instruction. There are special rooms set apart for women students.

All the lectures and courses of practical instruction may be attended by medical students who are otherwise unconnected with the College.

All the diplomas of the College are open to students of either sex. Separate rooms have been provided, and careful provision made for the instruction and comfort of women students.

Prizes.—The Barker Prize, £26 5s. ; the Carmichael Scholarship, £15 ; the Mayne Scholarship, £8. The Gold and Silver Medals in Surgery and the Stoney Memorial Gold Medal in Anatomy.

Class Prizes of £2 and £1, accompanied by silver medals if sufficient merit is shown, will also be given

in each subject. Prospectus and Student's Guide can be obtained on written application to the Registrar, Royal College of Surgeons, Dublin.

UNIVERSITY COLLEGE, DUBLIN.—This College is a constituent college of the National University of Ireland, for whose examinations and degrees it trains students. The examinations are conducted by the professors in the College, in conjunction with extern examiners appointed by the University.

Medical students must be registered with the Branch Medical Council at the commencement of their period of study. Forms of application can be obtained and filled up in the College. Information in respect of the necessary conditions for registration may be obtained from the Registrar of the College at the Medical School. The student must bring with him the certificate of his Matriculation examination, or of the Senior Grade examination of the Intermediate Education Board in the necessary subjects, and his birth certificate. Non-matriculated students intending to study medicine must have passed a Preliminary Examination, accepted by the General Medical Council, in English, Latin, Mathematics, and a Modern Language or Greek. Intending medical students who, for any reason, cannot begin the study of Medicine in the Winter Session, may do so in the Summer Session, but will not be able to complete the lectures of the first medical year until the following Winter Session.

The Scholarship Regulations provide for Six Scholarships of £30 each, tenable for one year in each of the 2nd, 3rd, 4th and 5th years of study. The Examinations for the Scholarships are held in October, the subjects being those studied in the previous year which Candidates must have attended in the College. Scholarships tenable for one year are offered at entrance at an Examination common to all Faculties.

There are Exhibitions of the value of £20 and £10 offered to students of the College at each of the Medical Examinations of the University; and a Gold Medal to the most distinguished answerer at the M.B., B.Ch., and B.A.O. Examination of the year.

Courses of lectures in Dental Surgery and Dental Mechanics are given to Dental students.

THE QUEEN'S UNIVERSITY OF BELFAST.—This University provides all the classes required for a complete medical curriculum. The University contains laboratories in connection with the departments of Biology, Chemistry, Physiology, Pathology, Anatomy, Physics, and *Materia Medica*. In connection, too, is a Students' Union, which gives students the advantage of dining-rooms, reading-rooms, a library, and various recreation rooms. Women are eligible as students. Clinical instruction is given at the Royal Victoria Hospital, which was rebuilt a few years ago, and has 300 beds, and at the Mater Infirmorum Hospital, which has 160 beds. Other hospitals open to the students of the University are: The Maternity Hospital, the Ulster Hospital for Women and Children, the Hospital for Sick Children, the Ophthalmic Hospital, the Benn Ulster Eye, Ear, and Throat Hospital, the Union Infirmary and Fever Hospital, the Fever Hospital, Purdysburn, and the District Lunatic Asylum.

Scholarships.—(1) Seven Entrance Scholarships value £20-£40; (2) two Dunville Studentships (one each alternate year), value £150 each; (3) one Andrews Studentship each alternate year, value £145; (4) numerous sessional prizes.

Sixteen scholarships, value £15-£40, are now open for competition at the medical examinations in March and June. There is also a Post-Graduate Research Fund open to all graduates of not more than three years' standing. Information regarding these scholarships, etc., may be obtained on application to the Dean of the Faculty of Medicine.

Fees.—The cost of the curriculum intended for students proceeding to the degrees of the Queen's University of Belfast is, approximately, £105. This includes examination fees and a perpetual ticket for attendance at the Royal Victoria Hospital or the Mater Infirmorum Hospital, but not fees for the special hospitals. The course for the Conjoint Board costs about the same amount.

A pamphlet containing full information regarding the new regulations for courses, fees, etc., can be had free of cost on application to the Secretary, Queen's University, Belfast.

THE UNIVERSITY COLLEGES—CORK AND GALWAY.—These important academic institutions educate students for all degrees and licenses, and are maintained, as hitherto, by Government grants. Various exhibitions and scholarships are available. Each college has the disposal of about £1,500 per annum in scholarships and prizes. The colleges are equipped with students' reading rooms and lending libraries and refreshment rooms, and with all adjuncts to collegiate life, such as literary societies and athletic organisations. The expense of living in the collegiate towns is quite moderate. The course of lectures in the winter session must be diligently attended, no student obtaining a certificate who has not put in three-fourths of a course. The scholarship examinations are held in October.

These Colleges are now constituent colleges of the National University of Ireland, and conduct examinations admitting to its degrees.

UNIVERSITY COLLEGE, CORK.—The arrangements in the Faculty of Medicine are made chiefly with reference to the requirements of the National University of Ireland, but students proceeding for the examinations of the Conjoint Boards of England, Scotland, or Ireland, can arrange the course of lectures which they attend, and the order in which they attend them, to meet the requirements of those bodies. Certificates of attendance in the college are also accepted by the University of London. The total fees for the college lectures and hospital attendances required by the National University of Ireland are about £104.

Clinical instruction is given at the North and South Infirmarys and at the Cork Union Hospital. Students can also attend the Mercy Hospital, the County and City of Cork Lying-in Hospital, the Maternity Hospital, the Hospital for Diseases of Women and Children, the Fever Hospital, the Ophthalmic and Aural Hospital, and the Eglinton Lunatic Asylum. The winter session commences on October 1st, and ends at the end of April. The courses of the summer session are delivered in the months of April, May, and June.

Between forty and fifty scholarships open to Medical Students are awarded annually (values £20-£50), as well as the Blayney Scholarship. This Scholarship, worth about £32, will be awarded to the candidate obtaining the highest marks in Honours at the M.B., B.Ch., B.A.O. Examination, held in Autumn at the College.

Further information can be obtained in the College Regulations, or on application to the Registrar, University College, Cork.

UNIVERSITY COLLEGE, GALWAY.—Clinical teaching is carried on in the Galway Hospital, established as a Public General Hospital (in the place of the County Galway Infirmary) by Act of Parliament 1892. The Galway Fever Hospital and Galway Union Hospital are also open to students. The conditions of Residence required by the National University for Graduation may be observed in Galway. The lectures qualify for the other Licensing Bodies.

Prizes.—There are eight Junior Scholarships in Medicine of the annual value of £25 each. Two are tenable by matriculated students of the first, second, third, and fourth years. There are, besides, private Foundation Scholarships open to medical students and tenable with medical scholarships. Sessional prizes are offered in each subject.

Like the sister College of Cork, this college is now a constituent college of the National University of Ireland.

ROYAL COLLEGE OF SCIENCE FOR IRELAND.

This College, situate in St. Stephen's Green, Dublin, supplies a complete course of instruction in science applicable to the industrial arts, especially those which may be cast broadly under the heads of Agriculture, Chemical Manufactures, Engineering, Physics, and Natural Science. A Diploma of Associate of the College is granted at the end of the three years' course. Non-

Associate students may join for any course required. There are several entrance scholarships, (a) in Agriculture, and (b) in Science and Technology, tenable for three years, of the value of £50 each yearly, with free tuition. There are four Royal scholarships of the value of £50 each yearly, with free education, tenable for two years. Two are competed for by the first year associate students at the end of each session. All the laboratories and drawing schools are open daily for practical instruction. The Science Scholarship Examinations are held during the first week in July, the Examinations for Agricultural Scholarships in the first week in September, and the Entrance Examination for intending Associates in the third week of September. For further particulars and copy of College Programme apply to the Registrar.

THE DUBLIN HOSPITALS.

THE clinical hospitals in Dublin are ten in number, exclusive of three lying-in hospitals. There are also two children's hospitals, an orthopædic hospital, a fever hospital, an ophthalmic hospital, a dental hospital, and other special institutions. Some of the clinical hospitals, though they have no actual or official connection with any school, are in close affinity with certain teaching bodies; while others, again, are without any special connection with any school. While, however, such association of school and hospital may exist, it should be remembered that the Dublin schools and hospitals are open to all comers, and the student is free to attend any hospital or any school he wishes, and to change his hospital from year to year as he may see fit.

The Irish licensing bodies require attendance on hospitals for twenty-seven months—*i.e.*, three winter sessions of six months and three summers of three months, within the five years of study. The fee at all general hospitals is £8 8s. in winter, and for the summer £5 5s., or £12 12s. for the entire session of nine months if taken together.

GENERAL HOSPITALS.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.—These hospitals contain over 300 beds. They are visited each morning at nine o'clock by the physicians and surgeons, and, in addition to the usual bedside instruction, clinical lectures are delivered on the most important cases. Instruction is also given on various special branches of medicine and surgery. The Truss Establishment, for the distribution of trusses to the ruptured poor of Ireland, is connected with these hospitals. There are ophthalmic, aural, throat, and gynæcological dispensaries, and instruction in these important subjects is given. A modern pathological laboratory, and a new mortuary have been opened recently. Twelve resident clinical clerks are appointed each quarter, and provided with furnished apartments, fuel, &c. The appointments are open not only to advanced students, but also to those who are qualified in medicine and surgery. A house surgeon for the Richmond Hospital and a house physician for the Whitworth and Hardwicke Hospitals are elected every six months, and receive a salary. The Richmond Lunatic Asylum, containing 1,200 beds, adjoins these hospitals.

MEATH HOSPITAL AND CO. DUBLIN INFIRMARY.—This hospital was founded in 1753, and now contains 160 beds available for clinical teaching. A new building for the isolated treatment of fevers, containing 40 beds, has recently been added. The certificates are recognised by all the universities and licensing bodies of the United Kingdom. Medical and surgical resident pupils and clinical clerks and dressers are appointed every three months, and two house surgeons are elected annually. A prospectus giving the complete arrangements for medical and surgical classes for the coming session may be obtained from the Secretary of the Medical Board, Mr. Henry Stokes, F.R.C.S.I., 32, Upper Pembroke Street.

THE ADELAIDE MEDICAL AND SURGICAL HOSPITALS occupy a central position within a few minutes' walk of the College of Surgeons and Trinity College. From October 1st, the physicians and surgeons visit

the wards and give instruction at the bedside at the advertised hours. There is a large detached fever hospital, and there are wards for infants and children. Operations are performed, at 10 a.m. on Tuesday, Thursday, and Friday. Special hours are devoted to clinical instruction in the diseases peculiar to women; also special instruction is given on practical pathology and X-ray photography. Two House Surgeons are elected annually and four resident pupils half-yearly. Prize examinations for the Hudson Scholarship of £30 and a gold medal, and Hudson prize of £10 and a silver medal, and for surgical, medical and dermatological prizes, are held at the termination of the session. The large dispensaries afford facilities for the study of ear, throat, and cutaneous diseases, as well as of minor surgery and dentistry. Further particulars from Dr. H. T. Bewley, 89 Merrion Square.

THE ROYAL CITY OF DUBLIN HOSPITAL.—This hospital has recently been enlarged and improved. A special course of instruction is given in ophthalmic and aural diseases. There are special wards for the treatment of diseases of the eye, of children, and of women, and practical instruction is given on diseases peculiar to women; there is also a separate building for infectious diseases. Clinical clerks to the physicians and dressers to the surgeons are appointed from the most deserving of the class. A new operation theatre, sterilising room, and anæsthetic room have been constructed in accordance with modern surgical requirements. A department for Röntgen-ray and light treatment of lupus has been added. A resident medical officer is elected annually, and resident medical and surgical pupils are appointed from among the past and present students of the hospital. Operations are performed on Tuesdays, Thursdays, and Saturdays, at 10 a.m. Special classes for first year students. Full particulars can be had on application to Hon. Sec. Med. Board.

SIR PATRICK DUN'S HOSPITAL is situated on the south-eastern side of the city, and about a quarter of a mile from the University School of Physic. It is officered almost exclusively by the professors in that school. Formerly all University students were compelled to attend this hospital, which was purely a medical institution, but many years ago the obligation was removed, and the hospital was opened for surgical cases. It is now open to all students. There is a special wing devoted to fever cases, and regular clinical instruction is given by the members of the medical staff throughout the winter and summer sessions. Special classes for students commencing their hospital studies will be held in the wards during the months of October, November, and December. They will embrace the elements of medicine and surgery, including note-taking. Opportunities are also afforded to students for examining cases of throat, ear, and eye diseases, as well as for performing minor surgical operations and bandaging. In the X-ray Department opportunities are given the members of the hospital class of seeing the various applications of the X-rays to the diagnosis and treatment of injury and disease. Arrangements have been made for practical instruction in anæsthetics. A department for dentistry has lately been added.

MATER MISERICORDIE HOSPITAL, Dublin.—This hospital, at present containing 345 beds, is open at all hours for the reception of accidents and urgent cases. Clinical instruction is given by the physicians and surgeons at 9 a.m. daily. A course of clinical instruction on fever is given during the winter and summer sessions. A certificate of attendance upon this course, to meet the requirements of the licensing bodies, may be obtained. Ophthalmic surgery is taught in the special wards and in the dispensary. Surgical operations are performed on Mondays, Tuesdays, Fridays and Saturdays at 11 o'clock. Connected with the hospital are extensive dispensaries, which afford valuable opportunities for the study of general medical and surgical diseases and accidents. Instruction is given in pathology and bacteriology. Three

house physicians, six house surgeons, and 16 resident pupils are elected annually. Dressers and clinical clerks are also appointed, and certificates are given to those who perform their duties to the satisfaction of the staff. Leonard Prizes are offered for competition annually. For further particulars see prospectus. Certificates of attendance upon this hospital are recognised by all the universities and licensing bodies in the United Kingdom. A training school and a home for trained nurses have been opened in connection with the Hospital.

Terms of attendance.—Nine months, £12 12s.; six winter months, £8 8s.; three summer months, £5 5s. Entries can be made with any of the physicians or surgeons, or with the Registrar, Dr. Martin Dempsey, 35 Merrion Square. A prospectus containing in detail the arrangements for clinical instruction, prizes, etc., may be obtained from the Secretary, Medical Board.

MERCER'S HOSPITAL.—This hospital, founded in 1734, is situated in the centre of Dublin, in the immediate vicinity of the Schools of Surgery of the Royal College of Surgeons, the National University School of Medicine, and Trinity College. It contains 120 beds for medical and surgical cases, and arrangements have been made with the medical officers of Cork Street Fever Hospital whereby all students of this hospital are entitled to attend the clinical instruction of that institution. There is a large out-patient department, and a special department for diseases peculiar to women. There are also special wards for the treatment and study of children's diseases. During the past few years the hospital has undergone extensive alterations in order to bring it up to modern requirements. A house surgeon is appointed annually. Five resident pupils are appointed, each for six months, and clinical clerks and dressers are appointed monthly from among the most deserving members of the class. The certificates of this hospital are recognised by all the licensing bodies. For further particulars apply to Mr. Seton Pringle, F.R.C.S., 27 Lower Baggot Street, Dublin.

ST. VINCENT'S HOSPITAL was established in 1834. It has 160 beds, and in connection with it there is a largely attended dispensary, and a nurses' institute. In addition to the ordinary clinical instruction, systematic courses of lectures are given in each department of medicine and surgery, and are illustrated by cases in the hospital. The resident officers consist of two house surgeons, two house physicians, and six resident pupils. Three clinical lectures are delivered daily in the wards, illustrated by selected cases, and beginning at 9 a.m. Two gold medals and other valuable prizes and certificates of merit are awarded at the end of each session. A prospectus can be had from Mr. Kennedy, 68 Merrion Square.

DR. STEEVENS' HOSPITAL, situated at Kingsbridge, is one of the oldest and largest clinical hospitals in Dublin, and contains over 200 beds. A new dispensary and out-patient department has been completed and opened to patients. There is accommodation for twelve resident pupils—four medical, six surgical, and two in the special departments, each of whom is supplied with a separate room. All information with regard to these appointments can be had from the Resident Medical Officer at the hospital. Licensing bodies recognise six months' residence as equivalent to a year's ordinary attendance at hospital. The manufactories and railway works in the neighbourhood supply this hospital with large numbers of accidents and other cases, while a special ward for venereal diseases affords exceptional opportunities for the study of this important subject.

JERVIS STREET HOSPITAL is the oldest established in Dublin. The new building was completed in 1896, since which time it has been open for the reception of patients. In addition to large medical and surgical dispensaries, the new out-patient department which is now completed, includes special departments for the treatment of diseases of the skin, eye, ear, and throat, and diseases peculiar to women. Four resident surgeons are appointed annually.

Clinical clerks and surgical dressers are selected from among the most attentive of the advanced students without the payment of any additional fee. Twelve resident students are appointed annually. Special certificates are given to resident pupils and dressers who have performed their respective duties to the satisfaction of the physicians and surgeons.

Students of Jervis Street Hospital are entitled to attend free of charge special courses in fevers at Cork Street Fever Hospital. Prospectus and all particulars may be obtained from the Hon. Secretary of the Medical Board, Dr. F. X. Callaghan, 25 Westland Row, Dublin.

SPECIAL HOSPITALS.

The chief of the special hospitals of Dublin are the Rotunda, the Coombe, and the National Lying-in-Hospitals, Cork Street Fever Hospital, the Royal Victoria Eye and Ear Hospital (amalgamation of St. Mark's Ophthalmic Hospital and the National Eye and Ear Hospital), the Dental Hospital, the Orthopædic Hospital, and the Children's Hospitals in Harcourt Street and in Temple Street.

THE ROTUNDA HOSPITAL.—This institution is the largest and the oldest gynaecological and maternity hospital in the British Empire. The work performed by it is about three times greater than that of any other hospital of its kind in Ireland. The number of patients admitted to the hospital, and of those attended in the extern maternity has increased enormously within recent years. The routine daily work comprises the attendance on lectures on midwifery and gynaecology; practice in abdominal palpation; personal conduction of parturition both in the extern and the intern maternities; cystoscopic examinations; and attendance at the operative work of the hospital in which the students assist. The hospital affords exceptional advantages to qualified men, for they (if considered competent) are permitted a certain amount of practical operative work—viz.—use of forceps, curettings, perineorrhaphy, &c. A special afternoon class in gynaecology is held by the Senior Assistant, and one in special pathology by the Pathologist. Fee for each, £2 2s. per month.

The pathological laboratory under the direction of Dr. Rowlette has become an important feature of the hospital. Students can enter at any time for periods of one month or longer. Certificates of attendance are accepted by all the licensing bodies. The L.M. certificate is obtained by attendance at the hospital for six months, with the subsequent passing of an examination. A special certificate in gynaecology is presented to students whose work meets with the Master's approval. Paid clinical assistants are selected (from amongst those who have obtained the hospital L.M. certificate), for periods of six months. Women students can also reside in the hospital under conditions similar to men. The grounds of the hospital contain grass courts for lawn tennis and croquet, and a skating rink. There is also a full-size billiard table.

Fees for Pupils.—*Interns.*—One month, £6 6s.; two months, £9 9s.; three months, £12 12s.; six months, £21; single months other than the first, £4 4s.; board and lodging in the house per week, £1 5s. Night students (not resident in house), £6 6s. for first three months; £4 4s. for the second three months. For further particulars apply to the Master, Dr. Henry Jellett, Rotunda Hospital, Dublin.

COOMBE LYING-IN HOSPITAL.—This hospital, which devotes itself to the care of lying-in women, and to the treatment of diseases peculiar to women, was founded in 1826. The original hospital was removed, and the present maternity hospital erected in 1875. An up-to-date labour theatre and waiting ward were added in 1904. The new Gynaecological Hospital was finished in 1903. It contains two modern operating theatres. The former Gynaecological Hospital has been converted into sleeping rooms for resident pupils. The Pembroke Dispensary was opened in 1911. The hospital is situated centrally in a most densely populated district. In addition to a very large gynaecological practice, over 2,000 women are delivered annually. The Master visits the maternity

wards daily with the students at 9.30 a.m. This is followed by a lecture on midwifery. At 11 a.m. the gynaecological wards are visited; following this a lecture on gynaecology, physical examinations, and operations take place in the theatres. At 4 p.m. on Mondays, Wednesdays, and Fridays, the Master conducts the gynaecological out-patient dispensary. This dispensary affords students exceptional advantages of acquiring a thorough knowledge of gynaecological diagnosis. At 5 p.m. on Tuesdays and Thursdays, the Master conducts a special class in practical obstetrics, including palpation, auscultation, pelvimetry, and operations on the phantom. Lady medical students can reside in the hospital. Extern assistants are appointed from among the students as vacancies occur. These most responsible appointments afford the students every opportunity of making themselves competent in practical midwifery. Candidates for the diploma of the Coombe Hospital shall have their names on the books of the hospital for six months, during which time they shall attend as frequently as possible, and be present at 30 deliveries. They shall then present themselves for examination, and if found qualified will receive the diploma. The catering for the residents is in the hands of a competent house-keeper. Board and lodgings, £1 1s. per week. The students' quarters are comfortably furnished.

Fees.—Extern pupils (for full course of six months), £8 8s. This includes one month's residence in hospital. Intern pupils—one month, £4 4s.; each consecutive month, £3 3s.; six months and L.M. diploma, £18 18s. Board and lodging in the hospital, 18s. per week. Lady students, intern—one month, £5 5s.; each consecutive month, £4 4s.; six months and L.M. diploma, £18 18s. Registration fee, 10s. 6d. There is no extra charge for attendance at any of the dispensaries. Certificates of attendance from this hospital are accepted by all the licensing bodies.

***NATIONAL MATERNITY HOSPITAL.**—This institution, under the joint mastership of Dr. A. Horne and Dr. R. White, is situated in Holles Street.

***CORK STREET FEVER HOSPITAL** contains 266 beds. It is supported by subscriptions, an annual Government grant, and capitation grants for patients. Regular clinical instruction is given during the winter and summer sessions to those who desire a special course in fevers. There are also courses for the Diploma in Public Health. All particulars may be obtained on application to the Medical Superintendent.

THE NATIONAL CHILDREN'S HOSPITAL for the treatment of all non-infectious diseases peculiar to children, with which the Pitt Street Children's Hospital, founded in 1821, was amalgamated, contains 45 beds for the reception of cases of deformity and all other forms of surgical disease. There is a general dispensary for extern patients held daily from 10 to 11. Operations are performed on Saturday at 12 o'clock. Practitioners and students can attend on application to Sir Lambert H. Ormsby, F.R.C.S.I.

***THE CHILDREN'S HOSPITAL**, Temple Street, Dublin (under the care of the Sisters of Charity).—This institution is the largest children's hospital in Ireland. There are 100 beds available for patients; about 1,000 cases are admitted to the wards annually; and about 7,000 or 8,000 seen in the dispensary. A new operating theatre has recently been opened. It is fitted and furnished in the best possible fashion for present-day surgery. Special attention is given to orthopaedic surgery.

The hospital is recognised for clinical instruction in the diseases of children by those licensing bodies which require a certificate of instruction in this important branch of medical education. A nursing home is in connection with the institution, and trained nurses are always available for private cases. Senior students or others requiring a post-graduate course at the hospital should apply for full particulars to Dr. M. C. Staunton, hon. sec., or to any member of the staff.

THE INCORPORATED ORTHOPAEDIC HOSPITAL, IRELAND.—This hospital was founded in 1876, and contains 80 beds. It is available for every class of deformity

available for treatment. Particulars may be obtained from Miss Graves, secretary, at the hospital.

THE ROYAL VICTORIA EYE AND EAR HOSPITAL, Adelaide Road.—This hospital, which was opened in March, 1904, is an amalgamation of St. Mark's Ophthalmic Hospital and the National Eye and Ear Infirmary. The hospital contains 80 beds. Clinical instruction in diseases of the eye and ear, including the use of the ophthalmoscope and operations, is given daily from 10 till 1. Special classes for practical instruction in the use of ophthalmoscope, &c., and for the demonstration of cases, are formed from time to time.

THE INCORPORATED DENTAL HOSPITAL, Lincoln Place.—This hospital is the only special dental hospital in Ireland. It is officered by a strong staff of the leading dental surgeons of Dublin, and has a large *clientèle* and extensive practice among the Dublin poor. The fees are £12 12s. for each year's Dental Hospital practice, and proportionately smaller fees for shorter periods for surgeons and medical students. The term of pupillage in mechanical dentistry required by the various licensing bodies may be taken in the recently enlarged Hospital Laboratory. Particulars may be obtained from the Dean.

THE CITY HOSPITAL FOR DISEASES OF THE SKIN AND CANCER, Holles Street.—Senior students are admitted free to the practice of this hospital, which has a large out-patient attendance, with 15 beds for intern cases. Classes of instruction will be given at regular intervals during the winter and summer sessions in the use of the Finsen light, X-rays, high frequency currents and radium, with demonstrations on (1) the production and use of the Röntgen rays, (2) electric currents, direct and alternating, with description of resistances, rectifiers and transformers; (3) accumulators, their construction, use, and methods in charging; (4) vacuum tube, choice of tube for particular kinds of work; fluorescent screen, and how to localise foreign bodies.

BELFAST HOSPITALS.

ROYAL VICTORIA HOSPITAL.—Established 1791; incorporated by Royal Charter, 1875 and 1898. New hospital opened, September 17th, 1903. 300 beds; Convalescent hospital, 22 beds; Children's Hospital, 33 beds; Consumptive Hospital, 10 beds.

Clinical instruction in medicine and surgery is given each morning by the staff.

***MATER INFIRMORUM HOSPITAL.**—Established 1883. 160 beds. The New Mater Hospital, which was erected at a cost of over £50,000, was formally opened on April 23rd, 1900. During the year the intern patients numbered 1,525; accidents, 3,762, and cases treated in the Dispensary, 22,597; 389 surgical operations were performed with the most satisfactory results. The total number of patients who received treatment was 27,884, being an increase of 1,517 as compared with the year 1904. A notable feature is in the number of accident cases, as the hospital is conveniently situated in proximity to a large working-class population, and within easy reach of most of the public works.

THE BELFAST MATERNITY HOSPITAL (INCORPORATED).—Established 1794. 30 beds.—The practice of the Maternity Hospital, the certificate of which is recognised by all the universities and colleges, &c., is open to students. The fee for the session is £2 2s. Resident nurses are also received for training for a period of six months, and a diploma given which is recognised by public bodies. The hospital course is also recognised by the Central Midwives Board. Conditions for such on application to the Matron. During the year 1911, 567 patients were treated in the hospital, and 556 patients at their own homes. Besides this, 360 patients were dealt with in the extern gynaecological department. Clinical lectures and bedside demonstrations are given by members of the staff during both the winter and summer sessions. Students wishing to attend should apply to Dr. H. D. Osborne, 32 Lonsdale Terrace, Belfast, Hon. Secretary to Medical Staff.

Note.—Hospital was rebuilt in 1904 and removed

to new premises in Townsend Street. A Resident Surgeon is elected periodically.

***ULSTER HOSPITAL FOR CHILDREN AND WOMEN**, Mountpottinger, Belfast, is the only hospital in the large part of the city situated on the County Down side of the river. It is placed in a working-class district, and has a great field for its charitable operations. There are in the hospital about thirty beds for children and ten for women. There is an extern department for children open every week-day, except Saturday, from 9 till 10, and for women at 10.30, and a special department for diseases of the eye, ear, and throat on Tuesdays and Fridays from 9 till 10. During the summer and winter sessions, clinical instruction is given to students daily, operations being chiefly performed on Wednesday and Thursday. There is a resident midwife for extern work, and every facility is afforded students for attending their cases in the district.

HOSPITAL FOR SICK CHILDREN (INCORPORATED), Queen Street.—This institution, erected by voluntary donations, and supported by voluntary contributions, was opened for the reception of patients on April 24th, 1879. It consists of a medical ward with twenty-eight beds, and one of a similar size for surgical cases. It is strictly non-sectarian in its principles, and is open to all denominations. Children from birth to the age of 12 years, and not suffering from contagious disease, are admissible as in-patients. A large extern clinic is conducted in the out-patient department between the hours of 9 and 10 a.m., where children from birth to 14 years are attended to. An operating theatre has been found necessary in the extern department, and has been erected. During the winter session systematic courses of lectures and demonstrations in the medical and surgical diseases of infancy and childhood are delivered in the wards on Wednesday and Saturday of each week at 9 a.m. At the close of the session an examination is held, and a gold medal awarded if sufficient merit has been shown. A Convalescent Home is maintained at Carrickfergus, Co. Antrim, in connection with the Hospital.

OPHTHALMIC INSTITUTION AND EYE AND EAR HOSPITAL, Great Victoria Street, Belfast.—Established 1844. New hospital erected, 1867. Operation theatre added, 1902. New extern department, 1909. This hospital is situated on the main road between Queen's College and the Royal Victoria Hospital. It contains about 30 beds for intern patients, and a large extern department. The latter is open on Monday, Wednesday and Friday at 10 o'clock for eye cases, and on Monday and Thursday at 10 o'clock for ear cases. Special courses of instruction are given during the winter and summer sessions, but students can enter at any time, and can always obtain plenty of practice in ophthalmoscopic work. Full particulars may be had from Dr. Cecil Shaw, 29 University Square, Belfast.

ULSTER EYE, EAR, AND THROAT HOSPITAL.—Established 1871. New hospital opened 1874; 30 beds.

CORK HOSPITALS.

***NORTH CHARITABLE INFIRMARY**.—Established 1774. 110 beds. Special wards for treatment of diseases of women and children. The extern department is largely made use of, and the number of accidents treated is very large. Clinical instruction is given daily from 9.30 a.m. to 12 noon. A new and thoroughly up-to-date operating theatre has recently been added at considerable expense.

CORK SOUTH INFIRMARY AND COUNTY HOSPITAL.—Founded 1773. The hospital contains 100 beds, available for clinical instruction, 40 medical and 60 surgical. There are also special wards devoted to the treatment of diseases peculiar to women and children, and a large medical and surgical extern department.

Clinical instruction is given daily during the session from 9.30 to 11.30, in both the medical and surgical wards, and clinical lectures are regularly delivered.

Students are regularly instructed in the methods of

using the rays by practical demonstration on the cases requiring their use.

For further particulars apply to Norman I. Townsend, hon. sec.

VICTORIA HOSPITAL FOR WOMEN AND CHILDREN.—Established 1874. 70 beds. A large amount of work is done in this hospital to relieve the poor of Cork, Kerry, and other counties.

***COUNTY AND CITY OF CORK LYING-IN HOSPITAL**.—Established 1798. 17 beds.

***EYE, EAR, AND THROAT HOSPITAL**, Western Road.—Incorporated 1898. 35 beds. In-patients treated during year, 454; out-patients, 4,238. Clinical instruction is given during college session. Special demonstrations in the use of the ophthalmoscope, laryngoscope, &c., are given from time to time.

***FEVER HOSPITAL AND HOUSE OF RECOVERY**.—Established 1801, 110 beds.

***MATERNITY**.—Established 1872.

***MERCY HOSPITAL**.—Established 1857, 80 beds.

GALWAY HOSPITALS.

***COUNTY HOSPITAL**.—Established 1786, 60 beds.

* No answer to our request for information received from these hospitals.

IRISH PUBLIC SERVICES.

THE POOR-LAW MEDICAL SERVICE.

For several years past the unsatisfactory nature of the Irish Poor Law Medical Service, as a career for young practitioners, has furnished a theme for the opening addresses at the leading medical schools. In addition to the petty annoyances, the laborious and harassing duties, and the ever-increasing amount of clerical work which the new orders of the Local Government Board impose from time to time, the unfortunate medical officers are grievously underpaid, their salaries being totally out of proportion to the duties discharged, and in the majority of rural districts barely sufficient to cover the out-of-pocket expenses, such as are incurred in the keep of a horse and man, and other servants. The Local Government Board has recently laid down, moreover, that the dispensary patients have the first call on the time of the medical officer, and that, even if he is engaged on an urgent private case, he must give it up and go off to attend on a "scarlet-runner," as the dispensary visiting tickets are not inappropriately called. So strictly is he bound to the discharge of his duties that unless incapacitated by sickness or other cause, or with the permission of the guardians expressly granted, he cannot leave his district for a single day, even if he makes provision for the performance of his duties in his absence by a brother practitioner. The Irish Medical Association, whose work includes the safeguarding of the interests and the improvement of the condition of the Poor Law medical officer, considers it an imperative duty to point out to young practitioners the following facts: (1) That the Poor Law Medical Service is one in which there is no promotion. (2) That it is a service where few facilities exist for original research, and still less for further medical culture, especially in the rural districts. (3) That, while medical education has become wider in its requirements, and more costly and difficult to procure, almost the same rate of payment as was given to less-educated men forty years ago is still offered, and this, too, at a time when the rural prosperity of the country is less, and consequently lucrative private practice more difficult to obtain. (4) That there is no compulsory superannuation, and, as a consequence, many old and infirm men are forced to remain in the service long after they have become unfit to discharge the duties, seeing nothing but extreme poverty and perhaps the workhouse itself staring them in the face.

We need go no further than to say that the Irish Poor Law Medical Service is in most cases a service to avoid. We therefore strongly urge on young medical men the importance of supporting the interest of the profession and their own, by refraining from applying for vacant posts of which the salary is insufficient.

There are about 160 workhouse and about 810

dispensary medical officers. The salary in this service is said to average about £114, and when it is taken into consideration that in the vast majority of rural districts it is necessary to keep one or more horses, the average area being from forty to sixty square miles, it is plain that there will not be a large margin left from the public emoluments.

The dispensary medical officer is also *ipso facto* the registrar of births, marriages, and deaths, and medical officer of health for the district, under the Public Health Act, passed in 1873 and amended in 1878. The former office, in country districts, yields between £5 and £10 a year, and the emoluments of the latter appointment in very few cases reach £20, averaging about £12. The medical officer is also vaccinator for the locality, and is required to vaccinate everyone who applies. For each patient a fee of 2s. is paid, along with his salary, by the guardians, and the sum total of those fees varies, according to the populousness of the district, from £4 to £100, an average for the provinces being about £10.

Qualifications.—The qualifications required by the Local Government Board are a licence in surgery, in medicine, and in midwifery; but registration in the "Medical Register," if effected since the passing of the Medical Act, in 1886, fulfils all requirements. The candidate must also be 23 years of age. Candidates recently qualified must possess a certificate of competence in vaccination.

Duties.—The duty of the dispensary doctor is twofold. He has to attend his dispensary or dispensaries on a given day or days in the week. He has also to visit at any hour of the day or night a sick person for whose relief a visiting ticket has been issued and to continue his attendance as often as may be necessary to the termination of the case. Moreover, he has many books to keep and a multitude of returns to make, and in most districts he has to make up all the medicines for the poor.

Workhouse Hospitals.—The number of unions in Ireland is 159, to each of which is attached one or more medical officers, appointed and controlled by the board of guardians in the same manner as the dispensary medical officer. The salary is about the same as that of the dispensary doctor, and the duties of a more easy and satisfactory description, inasmuch as they are confined to daily attendance at the workhouse hospitals, and no night visits out of doors or long journeys across the country are involved.

THE IRISH LUNACY SERVICE.

This service, at present, affords a comfortable livelihood for 22 resident medical superintendents and 32 assistants. The superintendents receive salaries and allowances ranging, according to the number of inmates of the asylum, from £500 to £1,000 a year, and the assistants receive salaries and emoluments averaging about £200 to £300 a year. There are also a few visiting physicians receiving about £120 a year, but this class of officer is being allowed to die out, and no new appointments will be made. The superintendents and assistants must devote their whole time to their duties.

Formerly the appointments of medical superintendents were in the patronage of the Lord Lieutenant, but, under the Local Government Act, they are in the hands of the asylum committees, with the proviso that no one shall be appointed who is not a fully registered practitioner with five years' service as assistant. The assistant is also appointed by the committee. In addition to these officers, there are, in certain larger asylums, clinical residents, who receive about £50 a year and full allowances. These appointments afford excellent introduction to the higher places in the service.

TUBERCULOSIS SERVICE.

Most of the county and county borough councils are proceeding to appoint tuberculosis officers to carry out work under the Tuberculosis Prevention Act (1908) and the National Insurance Act (1911). The duties proposed are usually (1) to act as superintendent of the county sanatorium; (2) to conduct one or more

tuberculosis dispensaries; (3) to act as consultant with practitioners in regard to tuberculous patients; (4) to conduct a bacteriological laboratory; (5) to act as adviser to the local insurance committee and the county council in regard to tuberculosis; (6) to organise and conduct anti-tuberculosis work generally in the county or county borough.

The tuberculosis officers must give their whole time to their duties. The salaries offered vary from £350 to £500 a year, with an allowance for expenses. The lower figure must be regarded as quite inadequate, and candidates before applying for such posts should satisfy themselves that the conditions of service have been approved by the local medical profession.

OTHER APPOINTMENTS.

There are, in addition to those which we have mentioned, certain appointments open to medical practitioners in special localities. They are:—

(1) Surgeoncies to the county infirmaries. (2) Attendance on the Royal Irish Constabulary. (3) Attendance on the Coastguards. (4) Factory Surgeoncies. (5) Attendance upon the depot soldiers who are not otherwise provided for. (6) Attendance on Postal Officials. (7) Prison Surgeoncies.

In each county is an infirmary or public hospital, to which one or more surgeons are appointed. In most cases the surgeon receives a salary of about £120 a year, and the appointment is in the hands of the infirmary committee, which is nominated by the county council. Some of the recent appointments have been honorary. The position is a pleasant one, and gives scope for modern surgical work. It is considered the best introduction to county consulting work.

The Constabulary are paid for at the rate of 2s. per month for each member of the force on duty in the district, including the wives and children of the men, but not of the officers. This includes the supply of medicines. The appointment to this position rests with the Inspector-General of the Royal Irish Constabulary, who usually acts upon the advice of the local district inspectors as to the convenience of the men, and, of course, the emoluments depend on the number of Constabulary stations and the number of men in each.

The Coastguard Service.—The duty of the medical officer is to attend the men when sick and to examine candidates either for admission or for superannuation. The fees vary from 5s. to 2s. 6d. per visit. The appointments rest with the Admiralty, but are usually secured for the local Poor Law medical officer. The emoluments depend on the number of stations and men, which are now very few.

Factory surgeoncies are in the gift of the Chief Inspector of Factories in Whitehall. There is a set scale of payment by the factory owner to the inspector for this work, but we believe it is not adhered to, and, in some districts, at all events, the emolument is a matter of arrangement. The amount depends upon the size of the factory, the position being, in Dublin or Belfast, or in other large manufacturing centres, a lucrative one, but in other places scarcely worth taking. The attendance on the military depôts is not worth mentioning.

Attendance upon postal servants is badly paid, except in the large towns, and the inspecting and sanitary duties are onerous.

Surgeons to the prisons are appointed by the Lord Lieutenant. The salaries for visiting surgeons vary from about £40 a year to £150. In the larger prisons there are whole-time surgeons.

Scotland.

In London the hospital is the unit of the medical school; in Scotland medical education is centred round the four Universities. It is not drawing any invidious comparison to say that Edinburgh occupies the premier place among the sister Universities as a medical school. Her long tradition alone justifies the statement. It is true that, as in so many other departments of activity, a levelling-up process has been going on in recent years, and probably there is less difference between the Scottish schools as regards efficiency and the excellence of their teaching than in the past, when Edinburgh stood *hors concours*. It is, therefore, very much a matter of convenience, or of fancy, which University the student seeks. Naturally, to those with no local ties, the prestige attaching to the Edinburgh degree proves attractive, and the number of graduates from overseas who attend the University is proof that its reputation is not declining. In addition to the University degrees, one other qualification to practice can be obtained in Scotland—the joint licences of the Royal College of Physicians, the Royal College of Surgeons, Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. The standard of examination for the triple qualification (as it is called), though lower than that of the Universities, is yet high enough to test the abilities of the candidates, if one may judge from the number of rejections. The standard, too, is being gradually raised. One characteristic feature of the Scottish medical schools is the existence, side by side with the University, of extra-mural schools, independent in every respect of the University, and recognised by the latter as schools whose classes qualify for graduation. The extra-mural teachers are all hospital physicians or surgeons, or specialists in their various branches; their remuneration depends on their power of attracting students; they are exposed to free competition; they are therefore under the constant necessity of teaching up to their very best, since any slackness is at once followed by a diminution of the students attending their class. The extra-mural school has come through many trials of late. Among these has been the effect of the Carnegie bequest, which has allowed many students, who probably would in the ordinary course of events have attended the extra-mural classes, to become University undergraduates. The proposed introduction by the Universities of a composition fee for the medical curriculum is viewed by the extra-mural lecturers with dislike, because it is feared that if it comes into effect the number of extra-mural students will again decline, and this, to an unendowed school, renders it difficult to maintain the pitch of efficiency demanded by present-day requirements. During the last few years the medical curriculum has been subjected to the most careful scrutiny by various bodies who have personal knowledge of the requirements of the students, and it has undergone, and is still undergoing, great changes for the better. The general interest which has been shown in the curriculum is encouraging to its reformers, and has removed the reproach that Edinburgh was content to rest on the laurels of the past. It may now be said, without fear of contradiction, that the education given in the Scottish schools generally has no need to fear comparisons. Weaknesses exist, of course, but no one is more conscious of these, or more anxious to remedy them, than the teachers. Though the University and extra-mural students do not meet in the class-room, they rub shoulders in the course of their clinical work—hospital, dispensary and maternity. The dispensary system is peculiar to Scotland; what we know as a dispensary differs entirely from a dispensary in the English sense of the word. A dispensary is an out-patient clinic, separate from any hospital, staffed by honorary medical officers, and attended for instruction by students. Not the least important part of the student's curriculum is his attendance for several months on out-door patients in their own homes under the same

conditions as obtain in practice among the lower working classes. University students have the privilege of working under extra- as well as intra-mural teachers, while men going up for the triple qualification are limited to the latter. It is not uncommon, however, for a man to come up intending to take the licence, and to change his mind and go in for a degree, or *vice versa*, and this can usually be done without much trouble or added expense, provided the change is made early in the course. The maternity training is still a weak spot in the Edinburgh curriculum, and many students are in the habit of going to Dublin or Glasgow for their practical midwifery. Great difficulties apparently stand in the way of making the work in Edinburgh what all its teachers would like—among them the material which is required for training midwives under the new Act—and though amalgamation of various institutions, and the opening of a residency in connection with the maternity hospital, have done something to improve matters, they have, to a certain extent, fallen short of what was hoped. When all is said and done, however, the Scottish graduate or diplomate receives an excellent training in his profession, and it can no longer be said that his course, though good in theoretical subjects, is defective in practical work. Clinical instruction is now having the closest attention directed to it, and systematic lecturing no longer fills the premier place that it once occupied. It is impossible to make any very definite statement as to the relative cost of a medical education in the different schools, as compared with London and Dublin, as so much depends on the extra classes taken out, the mode of living, and so on. The minimum inclusive fees for the licence are £120, for the M.B. degree about £146; but almost every student finds it practically necessary to attend additional classes. On the whole, the cost of living is highest in Edinburgh, lowest in Aberdeen; in the former, while the rent of lodgings is lower than in London, maintenance, including clothing and provisions, is somewhat more expensive. Incidental expenses, amusements, etc., are, however, considerably less in the Northern capital. In Aberdeen, money goes much further than in the south, and the student ought to keep himself on about two-thirds of the funds required in Edinburgh.

THE CARNEGIE TRUST.

Through the munificence of Mr. Andrew Carnegie, LL.D., payment is now made "of the whole or part of the ordinary class fees exigible by the Universities from students of Scottish birth or extraction, and of sixteen years of age or upwards, or scholars who have given two years' attendance, after the age of fourteen years, at State-aided schools in Scotland, or at such other schools and institutions in Scotland as are under the inspection of the Scottish Education Department."

The Trust provides for the payment of the class fees of the above students proceeding to graduation in medicine or science. Application for payment of class fees under the conditions of the Trust should be made to the Secretary, Mr. W. S. McCormick, Merchants' Hall, Edinburgh.

UNIVERSITY OF EDINBURGH.

Four degrees in medicine are granted; Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.E.), Doctor of Medicine (M.D.), and Master of Surgery (D.M.). The first two must be taken together, the last two may be taken separately.

No one is admitted to the degrees of Bachelor of Medicine and Bachelor of Surgery who has not been engaged in medical study for five years after passing a preliminary examination in general knowledge in accordance with the medical ordinances. A degree in Arts or Science of a British or other recognised University is held to supersede such preliminary examination. The subjects included in this general examination are English, Latin, elementary mathematics, and Greek, or French, or German.

The *annus medicus* of each year is constituted by at least two courses of not less than one hundred lectures each, or by one of such courses, and two

courses of not less than fifty lectures each, exclusive of the clinical courses. Two years of the five must be spent at the University, the remaining three years at any other Medical School recognised by the University Court.

During the first four years the student must attend botany, zoology, physics, practical chemistry, practical physiology, practical pathology, and medical jurisprudence during courses of not less than 2½ months each; public health, not less than forty lectures; practical anatomy, during two courses of not less than five months each; chemistry, anatomy, physiology, pathology, surgery, materia medica, medicine and midwifery during courses of not less than five months each. He must attend a course of twenty-five lectures on practical pharmacy, or have dispensed drugs for a period of three months in a recognised hospital or dispensary. He must attend a nine months' course in clinical medicine and in clinical surgery. During the fifth or final year he must be engaged in clinical study for at least nine months. In all, before graduation, he must have done hospital work for at least three years, and have acted as clerk in the medical and surgical wards and attended for six months the practice of a dispensary, or of a physician and surgeon. He must also have studied (1) operative surgery; (2) mental diseases; (3) *post-mortems*, fevers, and diseases of the eye, and (4) one of the following: Diseases of children, of the ear, nose and throat, or of the skin; (5) vaccination; (6) practical anaesthetics.

He must attend at least 25 cases of labour under the superintendence of a registered medical practitioner or 12 such cases, and, for at least three months, the practice of a midwifery hospital.

Each candidate is examined both in writing and *viva voce* :—

1. On zoology, botany, physics and chemistry.
2. On anatomy and physiology.
3. On pathology, and materia medica and therapeutics.
4. On medicine, surgery, midwifery, forensic medicine, and public health.

The order of examination (for students beginning in winter) is as follows:—Physics, end of first half of first winter; Chemistry, end of second half of first winter; Zoology and botany, end of first summer; Physiology, end of second summer; Anatomy, end of first half of third winter; Practical materia medica, end of second half of third winter; Pathology, end of third summer; Materia medica, end of second half of fourth winter; Medical jurisprudence and public health, end of fourth summer; Midwifery, Medicine and Surgery, end of fifth winter; Clinical medicine, surgery, and gynaecology, end of fifth summer. An interval of 3 months must elapse between the date of passing the systematic subjects and the date of appearing for the clinical subjects.

The degree of Doctor of Medicine may be conferred on any Bachelor of Medicine and Bachelor of Surgery, and who is of the age of twenty-four years, and who produces a certificate of having been engaged, subsequently to his having received the degree of M.B. and Ch.B., for one year in attendance on a hospital, or in scientific work bearing directly on his profession, or in the military or naval medical services, or for two years in practice other than purely surgical. The candidate shall submit to the Faculty of Medicine a thesis on any branch of knowledge comprised in the professional examinations for the degrees of Bachelor of Medicine and Bachelor in Surgery. The candidate will also be examined in clinical medicine and must show practical acquaintance with advanced methods of diagnosis; he may take gynaecology, mental diseases, or diseases of children for one of his three cases. The degree of M.D. is conferred on holders of the degrees of M.B., C.M. (Old Regulations) on the submission of a thesis approved by the Medical Faculty, provided that the candidate has passed the preliminary examination in the subjects of Greek and logic or moral philosophy. Should the candidate elect to do so, he may, however, take the M.D.

degree under the new regulations, *i.e.*, substituting an examination in clinical medicine for that in Greek and logic. This course is usually pursued by those who did not pass in these subjects with the rest of their preliminary examinations.

The regulations for the degree of Ch.M. are very similar.

Fees :—The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery is twenty-two guineas. The fee for the degree of Doctor of Medicine or of Master of Surgery is ten guineas (Old Regulations, £5 5s.).

The total expense of the curriculum, including examination and matriculation fee, is about £146.

Among scholarships, &c., open for competition during the session 1912-13 are the following:—Vans. Dunlop scholarships value £100, in preliminary subjects; Buchanan scholarship in midwifery, value £40; Mouat scholarship in practice of physic, £57; Allan Fellowship in clinical medicine and surgery, £55. There are also a great many other bursaries. Fellowships and prizes open during the session of 1912-13 and for the details governing entry for these the University Calendar (James Thin, South Bridge, Edinburgh) should be referred to.

Graduation in Public Health.—Degrees (B.Sc. and D.Sc.) are also conferred in Public Health. Candidates must be graduates in medicine and must matriculate for the year in which they proceed for examination. They must (1) have worked at least twenty hours a week during a period of eight months in a recognised Public Health laboratory—five of these months must be spent consecutively in the Public Health Laboratory of the University of Edinburgh; and (2) have attended a course of lectures on physics in addition to that qualifying for graduation in medicine, and one on geology.

Candidates for the second examination are not admitted until eighteen months have elapsed after having passed M.B., Ch.B., or sooner than six months after the first examination. They must have attended two courses of Public Health, one dealing with medicine, the other with engineering in relation to public health. They must also have studied practical sanitary work under a Medical Officer of Health for six months, have had three months' instruction in a fever hospital, and three months' instruction in mensuration and drawing.

Fees for Science Degrees: B.Sc., first examination, £3 3s.; B.Sc., second examination, £3 3s.

Diploma of Tropical Medicine.—Every year an increasing number of candidates avail themselves of the University Diploma of Tropical Medicine and Hygiene, which is conferred only on those possessing a degree in medicine. The course includes practical bacteriology, tropical diseases and hygiene, the zoological character and life history of disease-carrying insects and venomous animals, clinical instruction at an hospital for tropical diseases. The examination is held in January and July, the fee being £4 4s. A special certificate in Tropical Diseases is also granted under less stringent regulations, and after a shorter course.

Diploma in Psychiatry.—The course of study extends over one year, during which candidates must attend classes on (1) Anatomy and (2) Physiology of nervous system, (3) Pathology, (4) Bacteriology in relation to nervous system, (5) Psychology, (6) Clinical Neurology, (7) Psychiatry, (8), Clinical Psychiatry. There are two examinations, one on anatomy, physiology, pathology and bacteriology; the second on the remaining subjects. The fees amount to about thirty-seven guineas.

University Hall, Edinburgh.—In an educational number it is worth while calling attention to the advantages offered to students coming to Edinburgh to study, in the shape of social residences, in which students can live in a self-governing community. In each house there are private studies with or without bedrooms, and common sitting and dining rooms. The charges vary from 7s. 6d. to 22s. 6d. per week. The residents elect a treasurer from among

their number who acts as intermediary between them and the housekeeper or servants. It is a satisfactory indication of the comfort of the Hall that many graduates live in it and are willing to help or coach the undergraduates for moderate fees. To gain admission two references must be produced from past or present residents, or other suitable person. These are considered and voted on at a house meeting. The Hall is an admirable place for parents to send their sons to. Any unruly member may be expelled by a meeting of the residents similar to that held for elective purposes.

Medical School for Women.—Classes for women are carried on in the College of Surgeons and the New School, by Lecturers recognised by the University.

Information may be obtained, on application to the Dean, School of Medicine of the Royal Colleges, College of Surgeons, Edinburgh. Session begins October 1st, 1912. The classes qualify both for the Edinburgh University degree and for the Licence of the Triple Board, and are for women alone. The University of Edinburgh does not recognise certificates presented by female candidates for mixed classes without special cause shown. Women students are eligible for the benefits of the Carnegie Bequest.

UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and an examining body, but admits to examination only those candidates whose course conforms to its own regulations. Within certain limits provision is made for accepting instruction given by recognised medical schools and teachers; but not less than one half of the subjects other than clinical must be taken in this or some other recognised University entitled to confer the degree of M.D., and at least two years of the course must be taken in Glasgow University. Four degrees, open both to men and to women, are conferred—M.B. and Ch.B. (always conjointly), M.D. and Ch.M. A preliminary examination must be passed in (1) English, (2) Latin, (3) Mathematics, and (4) an Additional Language, namely, Greek, French, German, Italian, or other approved language, with possible option to students whose native tongue is not English in the case of the fourth subject, and, on passing, students must register in the books of the General Medical Council. For M.B. and Ch.B. a curriculum of five years is required. A syllabus with full details of the curriculum and of the preliminary examination may be had, post free, on application to the Registrar.

The fees for M.B. and Ch.B. are £23 2s.; for M.D. £15 15s., and for Ch.M. £15 15s. For hospital attendance there is an initial fee of £10 10s., with a further fee of £3 3s. for each winter session, and £2 2s. for each summer session, of clinical instruction. There are three very extensive general hospitals in the city, which afford exceptional opportunities for clinical work, while the Royal and other asylums, the City Fever Hospitals, the Maternity Hospital, the Sick Children's Hospital, the Eye Infirmary, &c., give facilities for the study of special branches.

The degrees of B.Sc. and D.Sc. in Public Health and of B.Sc. in Pharmacy, are also now conferred. Of late the University has made considerable efforts to extend its laboratory accommodation and equipment, to augment its teaching staff, and to encourage post-graduate and research work. Within recent years there have been provided new laboratories in the departments of pathology, anatomy (costing £13,000), chemistry, and surgery (costing £9,900); while new laboratories, to cost, with equipment, upwards of £50,000, have been erected for the departments of physiology, materia medica, and medical jurisprudence and public health.

Bursaries and prizes to the annual amount of about £1,000 are appropriated to medical students, including an Arthur bursary for women, £20 for three years.

Several bursaries open to students in any faculty are not infrequently held by medical students, and Scholarships and Fellowships to the annual amount of £1,600 may be held by medical students who have gone through the Arts course,

Queen Margaret College' for Women.—Founded in 1883 (by the Glasgow Association for the Higher Education of Women, which was formed in 1877 with the object of bringing University instruction, or its equivalent, within the reach of women), Queen Margaret College in 1890 added to its faculty of Arts a School of Medicine for Women. This was organised entirely on University lines, and with the view of preparing for University degrees; and when, in 1892, in consequence of the Ordinance of the University Commissioners authorising the Scottish Universities to admit women to instruction and graduation, Queen Margaret College became the Women's Department of the University of Glasgow, its classes in medicine taken previously to its incorporation with the University were recognised as preparing for the degree. A full course of study for M.B. and Ch.B. is given by University professors and lecturers, with excellent facilities for hospital and dispensary work in the Royal Infirmary and other hospitals. A Hall of Residence for the students was founded in 1894. Fees for the classes at Queen Margaret College may be paid by the Carnegie Trustees; and several bursaries are open to women students of medicine.

The Winter Session begins on 14th October. The prospectus can be obtained from the Mistress, Miss Melville, Queen Margaret College, Glasgow.

UNIVERSITY OF ABERDEEN.

The University of Aberdeen possesses under its charters the amplest privileges claimed or enjoyed by any academical institution. It confers degrees in the five faculties of Arts, Science, Divinity, Law, and Medicine. It also grants diplomas in Public Health, Agriculture, and in Education. It is, moreover, a teaching body equipped with twelve distinct chairs in the various branches of medicine and surgery. The majority of the professors devote their whole time to the work of the chairs. There are fully-equipped laboratories, the accommodation for which has recently undergone considerable extension. The degrees of M.B. and Ch.B. are conferred together; they cannot be obtained separately. The curriculum of study is nearly the same as in the University of Glasgow; the regulations in the preceding columns will therefore apply here. Two years must be passed at Aberdeen. With regard to fees, each candidate for the degrees of M.B. and Ch.B. must pay a fee of £5 5s. in respect of each of the first three professional examinations, and £7 7s. for the final examination. Total cost, exclusive of the fees for degrees, is about £120. Besides the Royal Infirmary, students have the opportunity of attending several other local institutions where special courses of instruction are given. Perpetual fee for hospital practice is only £6. The professional examinations are held twice in each year, namely, in March and July, directly after the close of the winter and summer sessions.

BURSARIES.—Bursaries, Scholarships, and Fellowships to the number of fifty, and of the annual value of over £1,180, may be held by students of medicine, (See "University Calendar.")

THE DEGREE OF M.D.—The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degrees of M.B. and Ch.B., is of the age of twenty-four years, and has been engaged subsequently to his having received the degree of M.B. for one year in attendance in a hospital, or in scientific research bearing on his profession, or in military or naval medical service, or for two years in medical practice, and has presented a thesis which has been approved of by the Medical Faculty. Candidates are required to pass an examination in clinical medicine in addition to presenting a thesis. Similar regulations apply to a degree of Ch.M. (Master of Surgery).

A Diploma in Public Health is conferred after examination on graduates in medicine in any University in the United Kingdom. Regulations may be seen in the "Calendar," or obtained on application to the Secretary of the University.

Aberdeen Royal Infirmary.—This is a well-equipped institution, containing 250 beds, and affords excellent opportunities for clinical study to students at

the Aberdeen University. The city, moreover, offers inducement in the way of cheaper living and comparative quiet to that obtained in Edinburgh and Glasgow, and will doubtless be preferred by some on this account.

ST. ANDREWS UNIVERSITY.

UNITED COLLEGE, ST. ANDREWS, AND UNIVERSITY COLLEGE, DUNDEE.

This University (session opens October 14th) grants the degrees of M.B., Ch.B., M.D., and Ch.M. The degrees of the University are open to either sex. For the degree of M.B., Ch.B., two of the five years of medical study must be spent in the University of St. Andrews; the remaining three may be spent in any University of the United Kingdom, or in any foreign, Indian, or Colonial University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. The preliminary examination and the professional examinations are of the same character as in the other Scottish Universities. A Diploma in Public Health is also granted by the University of St. Andrews to graduates in medicine of any University in the United Kingdom. Twelve months must elapse between the date of graduating in medicine and entering for the examinations for the diploma. The course of study required consists of (1) a six months' course of practical chemistry, bacteriology, and the pathology of diseases transmissible from animals to man in a laboratory of the University of St. Andrews; (2) six months' work with a medical officer of health; (3) three months' clinical instruction in infectious diseases. Subjects for first examination:—Chemistry, physics, bacteriology, and meteorology. Second examination:—Sanitation, sanitary law, vital statistics, medicine in relation to public health.

University College, Dundee, was affiliated and made to form part of the University of St. Andrews in 1897, and the whole medical curriculum may be taken at the medical school of that College. The United College, St. Andrews, offers classes for the first two years of professional study.

BURSARIES AND SCHOLARSHIPS.

United College, St. Andrews.—Nine T aylour Thomson bursaries for women, of the annual value of from £15 to £25 each—tenable for three years—preference to women medical students. Two Malcolm bursaries of the value of £25 each, tenable by men or women, for five years. Seventeen additional bursaries, including two of £50, one of £40, one of £30, six of £20, one of £15, and six of £10, are open to competition by students of medicine, arts, or science.

University College, Dundee.—Twelve entrance bursaries of the value of £15 each, and fourteen second and third year's bursaries of the value of £20 and £15 are open to competition. Two fourth and two fifth year's bursaries of £20 each are open to students who take the complete curriculum in Dundee. These are all tenable for one year. Other bursaries, of which the patronage is vested in trustees, are available.

The fees for the complete course, exclusive of the examination fees, amount to about £130.

Preliminary Examination.—The preliminary examination in Medicine will take place at the United College, St. Andrews, on September 13th, 14th, 16th, 17th, and 18th. Each candidate must apply to the Secretary for a schedule, to be filled up and returned not later than August 31st. The subjects of examination are: English, Latin, Elementary Mathematics, and Greek, or French or German, and the fee is half-a-guinea.

Fees.—Clinical medicine and clinical surgery, £4 4s. winter session; clinical medicine and clinical surgery, £3 3s. summer session; clinical obstetrics, £3 3s. winter session; £2 2s. summer session.

Fees for Degrees.—Total fees for M.B., Ch.B., are the same as at other Scottish Universities—i.e., 22 guineas (payable in instalments). Fee for the degree of M.D., and also for that of Ch.M., is 10 guineas in each case. For the Diploma of Public Health examinations the fee is £5 5s. for each of the two examinations.

Class Fees.—The fee payable in each of the following

classes is 4 guineas, *viz*:—Chemistry, physics, zoology, botany, physiology, anatomy, materia medica, pathology, forensic medicine, and public health, medicine, surgery, and midwifery. The fee for the practical classes in these subjects is 3 guineas each. In clinical surgery and clinical medicine, the fee is £4 4s.; ophthalmology, diseases of the throat, nose, and ear, diseases of the skin, and mental diseases, the class fees are 2 guineas each. The fee for Public Health chemistry required for the D.P.H. is 7 guineas. A special class in Bacteriology is also held for the D.P.H. for which the fee is 3 guineas.

Dundee District Asylum.—The appointments include two qualified resident assistants and two resident clinical clerks. Clinical instruction is given.

Dundee Royal Infirmary.—Clinical instruction is given at the Infirmary which contains 400 beds, with an annual average number of over 4,000 in-patients, and an annual daily residence of 280, with special wards for maternity cases, diseases of women, diseases of children, diseases of the eye, diseases of the ear, throat and nose, cancer, incipient insanity, and for cases requiring electric treatment. Five resident qualified assistants and an outdoor obstetric assistant are appointed annually. Clinical clerks and dressers are attached to the physicians and surgeons, and students are appointed to assist in the post-mortem room. The instruction given at the Infirmary is recognised for purposes of graduation by the Scotch Universities, the University of London, the University of Cambridge, the Royal University of Ireland, and by the Royal Colleges of England and Scotland. Hospital Tickets for the Infirmary, £2 2s. each session, or £3 3s. a year. Perpetual, £10 in one payment, or £10 10s. by instalments.

Further information will be found in the Calendar of the University published by Messrs. Blackwood and Sons, Edinburgh, the "Calendar of University College," Dundee (obtainable from the Secretary), or can be had from the Dean of the Medical Faculty, Professor J. A. Kynoch.

THE COLLEGES.

The Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow have arrangements by which the student may obtain the diploma of the co-operating bodies, and can register three diplomas under the Medical Acts—*viz.*, Licentiate of the Royal College of Physicians of Edinburgh, Licentiate of the Royal College of Surgeons of Edinburgh, and Licentiate of the Faculty of Physicians and Surgeons of Glasgow.

The three bodies grant their *single* qualifications only to candidates who are already registered as possessing another and opposite qualification in medicine and surgery as the case may be.

REGULATIONS OF THE CONJOINT BOARD OF THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH AND THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH AND THE ROYAL FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW.—The candidate must produce certificates of having attended the following course of lectures, the certificate distinguishing the sessions and the schools in which the courses were attended. Anatomy, six months; practical anatomy, twelve months; chemistry, six months; practical chemistry, three months; materia medica, three months; physiology, six months; medicine, six months; clinical medicine, nine months; surgery, six months; clinical surgery, nine months; midwifery, three months; medical jurisprudence, three months; pathology, three months. The candidates must also produce the following certificates:—(a) Of having attended six cases of labour under the superintendence of a registered practitioner. (b) Of having attended for three months' instruction in practical pharmacy. The teacher must be a member of the Pharmaceutical Society of Great Britain, or the Superintendent of a laboratory of a public hospital or dispensary, or a registered practitioner, or a teacher to a class of practical pharmacy. (c) Of having attended for twenty-four months the medical and surgical

practice of a hospital, containing eighty patients, and possessing distinct staffs of physicians and surgeons. (d) Of having attended for six months the practice of a public dispensary, or of having assisted for six months a registered practitioner. (e) Of having been instructed in vaccination.

First Examination, Fee £5.—The First examination shall embrace chemistry, physics, and elementary biology, and shall take place not sooner than the end of the first year, including a winter and summer session. Candidates who desire to enter for the first professional examination must produce certificates of attendance on chemistry, practical chemistry, anatomy, and six months' practical anatomy.

Second Examination, Fee £5.—The Second examination embraces anatomy and physiology and shall not take place before the termination of the summer session of the second year of study. Candidates must produce certificates of attendance on anatomy, practical anatomy, and physiology.

Third Examination, Fee £5.—Comprises the subjects of pathology, materia medica, and pharmacology and advanced anatomy.

Final Examination, Fee £15.—The Final examination embraces medicine (including therapeutics and medical anatomy, clinical medicine); surgery (including surgical anatomy and surgical pathology); clinical surgery; midwifery and gynaecology, medical jurisprudence and hygiene; and shall not take place before the termination of the full period of study.

Subjects of Preliminary Education: (1) English grammar and composition; (2) Latin, grammar, translation from specific authors and easy unseen translation; (3) (a) arithmetic, to vulgar and decimal fractions; (b) algebra, to simple equations; (c) geometry, to the first two books of Euclid; (4) elementary mechanics of solids and fluids, comprising the elements of statics, dynamics, and hydrostatics; (5) one of the following:—(a) Greek; (b) French; (c) German; (d) Italian; (e) any other modern language; (f) logic; (g) botany; (h) zoology; (i) elementary chemistry.

Qualification in Public Health.—The College of Physicians, in association with the Royal College of Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow, confers a certificate of competency in public health. The examinations are held in April and October. Fee, £10 10s.

For the special regulations of the Royal College of Surgeons of Edinburgh, intending candidates should apply to Mr. James Robertson, 48 George Square, Edinburgh; and for those of the Royal College of Physicians, to the Secretary.

The Fellowship of the Royal College of Physicians of Edinburgh is conferred only by election, and the candidate must have been a member of the college for at least three years, and have attained the age of twenty-seven years.

The Membership is conferred only on a licentiate of a college of physicians or graduate in medicine of a British or Irish University, provided he shall have attained the age of twenty-four years and shall have passed an examination on: (1) medicine, including therapeutics; (2) on one of the following optional subjects, in which a high standard of proficiency is expected:—(a) a department of medicine specially professed; (b) psychological medicine; (c) pathology; (d) medical jurisprudence; (e) public health; (f) midwifery; (g) gynaecology. The examination is of a searching character.

The fee for membership is 35 guineas, for fellowship 38 guineas, with a stamp duty of £25—£101 13s. in all.

The licence, or single qualification in medicine, is conferred on candidates who already possess a recognised qualification in surgery. The examinations for this licence are held on the first Wednesday of each month, save those of September and October, in medicine, materia medica, midwifery and medical jurisprudence. The fee is £15 15s., and intending candidates should communicate with the Secretary of the College at least eight days before the date of examination.

The Fellowship of the Royal College of Surgeons of Edinburgh is conferred (except under certain conditions as to age and professional standing) only on candidates

who have passed a special examination, and have previously obtained a diploma from the college, or from either of the Colleges of Surgeons of England or Ireland, or the Royal Faculty of Physicians and Surgeons of Glasgow, or the surgical degrees of the Universities of Great Britain, and who are twenty-five years of age. The subjects for examination for those who are already Licentiates of the College are on the principles and practice of surgery, clinical and operative surgery, and one optional subject.

Those who are not Licentiates of this College: on principles and practice of surgery, clinical and operative surgery, surgical anatomy, and one optional subject; and in such supplementary subjects as have not, in an adequate manner, been included in the examination for the registrable surgical qualification possessed by such candidates, and which are required in the examination for Licentiates of this College.

The optional subjects shall embrace: (a) Surgery, special branches; (b) advanced anatomy and physiology; (c) surgical pathology and morbid anatomy; (d) midwifery and gynaecological medicine and surgery; (e) medical jurisprudence and hygiene; (f) practice of medicine and therapeutics. The examinations are written, oral, and practical. Three weeks' notice must be given to Mr. James Robertson, from whom full particulars as to certificates required may be obtained. The fee is £30 for those who hold the diploma of Licentiate of the College, and £45 to others (no stamp duty is payable on the diploma). Registered practitioners, aged not less than 40, who have been in practice for not less than ten years, and who have highly distinguished themselves by original investigations, may under special circumstances be elected without examination. Women are not admitted to the Fellowship of either college.

LICENCE.—The examination embraces the principles and practice of surgery (including operative surgery and surgical pathology), clinical surgery, and surgical anatomy, and shall not take place before the termination of the full period of study. Fee, £15 15s.

DENTAL DIPLOMA.—Every candidate for the dental diploma must have attended the general lectures and courses of instruction required at a University or an established medical or dental school recognised by the College as qualifying for the diploma in surgery. The fee is £10 10s.

Edinburgh Royal Infirmary.—Clinical instruction is afforded at this institution, which contains 900 beds under the supervision of professors of the University and the ordinary physicians and surgeons of the Infirmary. Special instruction is given on diseases of women, physical diagnosis, diseases of the skin, eye, ear, throat and teeth, and anaesthetics. Separate wards are devoted to venereal diseases, diseases of women, diseases of the eye, also to cases of incidental delirium or insanity, and three wards are specially set apart for clinical instruction to women students. Post-mortem examinations are conducted in the anatomical theatre by the pathologists. The perpetual fee, on one payment, £12; the annual fee, £6 6s.; half-yearly, £4 4s.; quarterly, £2 2s.; monthly, £1 1s. Separate tickets amounting to £12 12s. entitle the student to a perpetual ticket. No fees are payable for any surgical or medical appointment.

The appointments are as follow:—

1. Resident physicians and surgeons are appointed and live in the house free of charge. There is no salary. The appointment is for six months.

2. Non-resident physicians and surgeons (in the special subjects and for out-patient work) are appointed for six months. These appointments may be renewed.

3. Clerks and dressers are appointed by the surgeons and physicians. These are open to all students and junior physicians holding hospital tickets.

4. Assistants in the pathological department are appointed by the pathologists to conduct post-mortem examinations in the anatomical theatre.

ROYAL HOSPITAL FOR SICK CHILDREN.—During the year three courses of clinical instruction are given by the staff of the hospital, who are recognised as University Lecturers on the subject. The course consists

of clinical lectures, ward clinics, attendance at *post mortems* and out-patient clinics. Hospital tickets, £1 1s.

SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, EDINBURGH.

The government of this school, established in 1505, is now vested in a board which is equally representative of the two Royal Colleges and the Lecturers, the school being styled "The School of Medicine of the Royal Colleges, Edinburgh." The present number of lecturers is about sixty, of whom the greater number deliver qualifying courses of instruction of the same duration and scope as those delivered within the University, while a large number of non-qualifying courses on special subjects of interest to medical science, but which are not required for graduation, are delivered both in the winter and summer sessions. The students who attend the classes of the School of Medicine are largely students proceeding to the University degree, as well as those who are intending to take other qualifications, such as the triple qualification of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow; that of the Royal College of Physicians of London, and the Royal College of Surgeons of England, and the degrees of the different Universities. The number of students attending the school averages 1,300 annually. For particulars apply to the Dean of the School, 11 Bristo Place, Edinburgh.

The minimum cost of the education in the School of Medicine for the triple qualification of physician and surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow, including the fees for the joint examinations, is about £120, which is payable by yearly instalments during the period of study.

The Winter Session opens October 8th.

GLASGOW EXTRA-MURAL SCHOOL.

St. Mungo's College and Glasgow Royal Infirmary.—This college was incorporated in 1889 under its present title, being formerly known as the Glasgow Royal Infirmary School of Medicine. The Medical Faculty occupies buildings erected for the purpose of the medical school in the grounds of the hospital. The college is equipped with a complete electric light installation, and a powerful electric educational lantern. Attendance on the classes in St. Mungo's College qualifies for the medical degrees of the Universities and the medical and surgical colleges in accordance with their regulations. A syllabus, giving details as to classes, fees, &c., may be had on application to the Secretary of the Medical Faculty.

The Royal Infirmary, which is at the service of the College for teaching purposes, is one of the largest general hospitals in the kingdom. It has 600 beds available for clinical instruction, in addition to an ophthalmic department, and it has special wards for diseases peculiar to women, venereal diseases, burns, and diseases of the throat, nose, and ear. At the dispensary special advice and treatment are given in diseases of the eye, ear, teeth, and skin, in addition to the large and varied number of ordinary medical and surgical cases which in a great industrial centre daily require attention. Students at the college and hospital get the benefit of dispensary experience free of charge, and no better or wider field for seeing hospital practice and receiving clinical experience can be found than in the Glasgow Royal Infirmary.

Appointments.—All appointments are open. There are five physicians' and ten surgeons' assistants, who obtain free board and residence in the hospital and act in the capacity of house physicians and house surgeons. There is also a house surgeon for the ophthalmic department. These appointments are made for six months, and are open to gentlemen who have a legal qualification in medicine and surgery. Clerks and dressers are appointed by the visiting physicians and surgeons. From the large number of cases of acute diseases and accidents of varied character received, these appointments are

valuable to students. Assistants are also appointed for the pathological department.

Fees.—The fees for Lectures, including hospital attendance necessary for candidates for the Diplomas of the English, Scotch, and Irish Colleges of Physicians and Surgeons, amount to about £80.

Royal Infirmary.—Fees: (1) Hospital attendance, dispensary, &c., perpetual ticket, £7; season ticket, six months, £2 2s.; three months, £1 1s. Separate payments amounting to £7 7s. entitle a student to a perpetual ticket on returning previous season tickets. (2) Clinical instruction, six months, £3 10s.; three months, £1 15s.

Dental Curriculum.—Students studying with a view to the dental diploma can obtain instruction in the following subjects: Physics, chemistry, anatomy, physiology, surgery, practice of medicine, and materia medica. The special dental courses may be obtained in the Dental School, 15 Dalhousie Street, Glasgow. Particulars may be had from D. M. Alexander, Esq., 97 West Regent Street.

Anderson's College Medical School, Glasgow.—Founded in 1800. The modern, excellently equipped buildings of this school are situated to the west of the entrance to the Western Infirmary, and within four minutes' walk of the University. Extensive laboratory accommodation is provided for practical anatomy, practical chemistry, practical botany, practical zoology, practical physiology, practical pharmacy, operative surgery and public health.

The various courses of instruction qualify for all the Licensing Boards in the United Kingdom, and for the Universities of London, Durham, Edinburgh, and Glasgow, under conditions stated in the calendars. The courses in public health (laboratory and lectures) are also recognised by the Universities of Cambridge, London, etc. Session opens 14th October, 1912. For syllabus, apply to the Secretary of the Medical Faculty, Anderson's College Medical School, Glasgow, W.

The Carnegie Trust pays the fees of students at Anderson's College on conditions regarding which particulars may be obtained from Sir W. S. McCormick, LL.D., Carnegie Trust Offices, Edinburgh.

Class Fees.—For each course of lectures (anatomy, ophthalmic medicine and surgery, aural surgery, diseases of throat and nose, mental diseases, and public health excepted), first session, £2 2s.; second session (in Anderson's College), £1 1s. For practical classes (except anatomy, chemistry, and public health), namely, botany, zoology, physiology, pharmacy, operative surgery, first session, £2 2s.; second session, £2 2s. **Chemistry.**—Lectures, £2 2s.; practical chemistry, £3 3s. **Botany and Zoology.**—Reduced fees for lectures with laboratory work in botany or in zoology, during same summer session, £3 3s.; for lecture class or practical class separately, in botany or in zoology, £2 2s. **Ophthalmic Medicine and Surgery** (including hospital practice), aural surgery, diseases of throat and nose, and mental diseases, fee for each course, £1 1s. **Anatomy Class Fees.**—Winter.—First session, lectures and practical anatomy, £5 5s.; practical anatomy alone, £2 2s. Second session, lectures and practical anatomy, £4 4s.; practical anatomy alone, £2 2s. Summer.—Regional course or special dental course (each including nervous system) and practical anatomy, £3 3s.; regional anatomy course or special dental course alone, £2 2s.; practical anatomy alone, £1 11s. 6d.; osteology and practical anatomy, £2 12s. 6d.; osteology alone, £1 11s. 6d. **Public Health Laboratory.**—Fee for six months' course £12 12s. **Matriculation Fee.**—For the year, 10s.; for one class alone in winter, 5s.; for summer session alone, 5s.

Western Medical School, Glasgow.—Situated in University Avenue, opposite the principal entrance to the University, this School is also near the Western Infirmary. The subjects taught are chemistry, anatomy, medicine, surgery, midwifery and gynaecology, ophthalmology and dermatology. Some of the classes qualify for graduation and for Scottish diplomas. The fee for most of the subjects is £2 2s.

There is no matriculation fee. Further particulars may be learnt from the Secretary, Mr. I. N. Morton.

Glasgow Maternity and Women's Hospital.—This institution is of ancient foundation, but the present buildings, containing 104 beds, with a large out-patient department, were only opened four years ago. Erected with due regard for the most modern requirements, and staffed by physicians of reputation, it affords excellent facilities for acquiring a complete knowledge of the art and practice of obstetrics. There is also a students' residence in connection with the hospital, in which board and residence can be had at very moderate fees. The hospital fee is £5 5s. Full particulars from House Superintendent.

Glasgow can boast of several other important medical institutions, such as the Western Infirmary, with a staff representative of the best in medicine and surgery of the second city of the Empire, and having no fewer than 500 beds. There is also the Victoria Infirmary, with 260 beds, in which leading specialities, such as ophthalmology, aural surgery, diseases of the throat, diseases of women, diseases of the skin, etc., are taught; the Glasgow Eye Infirmary, with 100 beds; the Royal Hospital for Sick Children, with 74 beds, etc.

FRANCE.

Paris, Sept. 7th, 1912.

THE GLANDS OF INTERNAL SECRETION.

THE researches of modern physiology have proved that certain vascular organs—as the thyroid, pituitary, ovaries, testicles, supra-renal capsules—are endowed with an internal secretion essentially necessary to the economy. Thus the total ablation or destruction of these endocrine glands is followed by the death of the animal in a very short time, accompanied by diverse phenomena, as convulsive movements, paralysis of the lower limbs, puffiness of the eyelids, hypothermia, dyspnoea, etc. The effect of the ablation of the thyroid body in man consists in general puffiness of the tegument. The skin is the seat of hard, elastic pseudo-œdema, uninfluenced by pressure of the finger; at the same time it is dry, rough and pale, while the hairs become fragile and fall in abundance.

The repartition of the pseudo-œdema produces a modification of the facies and the external habitus—swelling of the eyelids, tumefaction of the tongue, enlargement of the nose, thickening of the lips, general deformity of expression, giving to the face an aspect of stupidity and indolence. In the child may be added an arrest of the development of the skeleton.

In the functional point of view, the nervous system is particularly affected. Intelligence diminishes in the child, education is slow and almost impossible, and to this intellectual apathy is added physical apathy characterised by general indolence in the movements.

In 1884 Schiff assured having obtained different results according as he practised thyroidectomy on dogs or rabbits, the operation causing the death of the dogs, while the rabbits survived. These results provoked researches which completed the anatomical notions relative to the thyroid body. It was perceived that to the thyroid gland were annexed small organs of extremely reduced dimensions, to which the name of parathyroid gland was given, and in 1891 Glegg proved that the death of the rabbit was produced by the removal of these little organs as well as the thyroid gland. Hence ablation of the thyroid gland alone is consistent with life, but not so when the whole thyroid system is removed.

Later researches tend to attribute to a trouble in the function of the parathyroids infantile tetany, puerperal eclampsia, and Parkinson's disease.

Ablation or destruction in animals of the supra-renal capsules provoked rapid wastings, asthenia, lowering of the arterial pressure, acceleration of the

heart, and death followed in 10 to 20 days; pigmentation was never observed. All these symptoms are present in a modified form in Addison's disease.

Ablation of the ovaries during the active period of life is followed by atrophy of the breasts, obesity, heat waves, congestive phenomena, bearing principally on the lungs, headache, vertigo, palpitations, neurasthenia.

Ablation of the testicles is too well known to need repetition, for the somatic and physiological modifications have been observed from time immemorial in eunuchs.

Castration in the dog determines atrophy of the prostate. It was on this fact that was founded some years ago a method of treatment of hypertrophy of the prostate, a method now completely abandoned. The results obtained on animals by grafting the thyroid gland directed the physiological researches on the rôle of sanguineous vascular glands.

From the fact that thyroidectomy lost its dangers in animals on which was grafted a thyroid gland of another animal of the same species, it was permitted to conclude that it was by a product of internal secretion that the grafted gland warded off the dangers of thyroidectomy; that this product was contained in the juice or extract of the gland; and lastly that the injection or ingestion of this juice or extract would have similar and more permanent effects than that of the graft, which finishes by being absorbed or is transformed into a fibrous mass, deprived of all vitality. According to Sauvé, the grafted portion can never re-establish the internal secretion of the gland, and hence its inutility.

Of the two methods, injection or ingestion of the extract of the thyroid gland, ingestion should be preferred, and the same might be said of the other glands, except, perhaps, as regards the supra-renal capsules, of which the active principle, adrenaline, is well known since the discovery of takanine.

Injections of the capsular extract provoke an increase of the arterial tension, produce mydriasis, glycosuria, and improve the condition of rickets or osteomalacia.

Ingestion of the extract of the pituitary gland raises the arterial tension, slows down the pulse, increases diuresis, suppresses disagreeable sensations of heat and sudation, improves the appetite and sleep, exercises on the nutrition as well as on the osseous and muscular development a stimulating action.

Ingestion of fresh ovaries increases the strength of certain asthenic women, and possesses a dynamogenic action similar to that of the testicle.

Injection or ingestion of juice of the testicles of animals was introduced into the medical world by Brown-Séquard, who made known its dynamogenic action, both physical and physio-psychic.

All of these glands possess evidently an antitoxic action, for the troubles following the ablation or destruction might be compared with those provoked by the introduction of different poisons into the organism. Hence it is rational to admit that the endogenic poisons resulting from the normal function of the economy are neutralised by the product of secretions.

Positive proofs of this antitoxic action are not as yet obtainable, but it may be inferred from the fact that serum of animals subjected to ablation of a gland is toxic, and the curative effect of an injection of an extract in an animal from which the corresponding gland had been removed, and finally the defensive reaction of glands consecutive to infections or intoxications manifested by the histological aspects of the gland, revealing hyper-function due to an increase in the product of internal secretion capable of neutralising the toxins directly or indirectly introduced into the organism. (Gley.)

GERMANY.

Berlin, Sept. 7th, 1912.

AT the Medizinische Gesellschaft, Hr. Goldmann gave a note on

CLOSURE OF THE ABDOMEN AFTER SIMPLE CHOLECYSTECTOMY.

He said that in the great majority of patients who

came under treatment for gall-stones, the affection was limited to the gall-bladder. It was sufficient in such cases to do a simple cholecystectomy without opening the common bile duct at all. Instead of tampons and drainage in the majority of such cases the abdomen could be closed at once, as was already practised by a number of surgeons.

He would demonstrate a modification that had been practised by Professor Rotter for four years, one partly built up on observations made in acute inflammations of the cæcum.

Professor Rotter had determined that after operation for appendicitis, even when there had been diffuse peritonitis the abdomen could be closed at once if three indispensable conditions were present—there must be no defect of peritoneum, no gangrenous spot must be left behind, or in which any suppurative infiltration was present, and, lastly, the hæmorrhage must have been effectually stopped. In this case, when there could no longer be place for any secretion in the abdominal cavity the abdomen could be closed at once without drainage or tampons that rendered recovery so lingering.

He had also shown that drainage of the abdomen could only be effective for a very short time at most; adhesions soon formed even in a few hours that arrested all drainage.

Tampons had a similar effect, the part so treated at once became practically extraperitoneal. They were also superfluous so soon as the conditions laid down by Professor Rotter were fulfilled. In the case of the gall-bladder, however, two further conditions had to be satisfied. First the site of the gall-bladder must be so treated that no secretion from it could find its way into the peritoneal cavity, and, secondly, the cystic duct must be so closed that under no circumstances could bile from it enter the peritoneal cavity. In order to fill the first condition, it was necessary that the removal of the cyst should be entirely subserous. It was formerly a custom to remove the bladder direct, and this entailed a good deal of parenchymatous hæmorrhage, some small bile passages also were opened, from which a flow of bile could take place. When, on the other hand, the removal was entirely subserous, these passages were not opened as the whole process took place in a layer of connective tissue. In this way it was possible to arrest all bleeding as the points could be treated separately. The mode of procedure was the following: The serous covering of the gall-bladder was incised all round at about the distance of 1 cm. from the bladder, and the bladder removed from its connective tissue bed below. After removal, the serous edges around the wound were brought together and sutured by a continuous suture. The second condition was the closure of the cystic duct. This was accomplished by ligaturing the free end, forming a loop, so that the ligatured free end should lie over the spot at which it debouched into the common duct, where both were enclosed in a fresh ligature. The procedure was rendered more secure by a further detail. The peritoneum was removed from the cystic duct as far as its entrance into the common one, after the ligatures had been applied as mentioned, the peritoneal covering was again drawn carefully over the whole and secured in position.

They had never had any trouble in cases treated in this way. As a matter of course, if the cystic duct was at all diseased or there was any suspicion that it would not be safe to treat it in the way described, one would remove it down to its entrance into the common duct. During the four years that had elapsed since the introduction of the procedure there never had been any trouble that could in any way be attributable to the duct.

If the operation had been aseptic throughout, the sutures should be passed through all the layers of the abdominal wall, through peritoneum, muscle, fat and all.

If, on the other hand, there had been any infection during the operation, the peritoneum only had been closed at the time, the muscles were only brought

together by a few interrupted sutures, small strips of iodoform gauze were placed in the interspaces, and the fatty parts were broadly tamponed. As a rule, no abdominal hernia followed this method of treatment. In about one-third of their cases, however, they had been obliged to insert tampons, so that the method was not one that could be relied on absolutely. These were cases, in the first instance, in which the bladder could not be entirely removed through connective tissues, where it was atrophied it was very difficult to do this. Secondly, in cases of recent inflammation the peritoneum was soaked in œdematous infiltration, and became so tender that sutures would not hold easily. In such a case a tampon must be made use of.

The speaker then related in detail a number of cases in which the plan, above described, had been successfully carried out.

AUSTRIA.

Vienna, Sept. 7th, 1912.

THE ORIGIN OF SCLEROSIS.

At the Gesellschaft für Innere Medizin, Marburg discussed the various causes of sclerosis, and concluded by affirming that it was endogenic in nature, with a degeneration of the ganglionic cells, the parenchymaphase following as a secondary. Primary glia growths were only to be found in tumours, which he attributed to vascular injury in the foetal or infantile state, progressing slowly afterwards. The next group of cases were those coming under the head of multiple and diffuse sclerosis, recognised as inflammatory. The first of these usually commence in the infantile period after infectious diseases, such as measles, diphtheria, scarlet fever and pertussis, and is characterised by a slow, insidious growth, and intermittent and nonfebrile in its course, according to the site affected. This form is accompanied at an early stage with loss of abdominal reflex, indicating a degeneration of the central structure of the nerve, which is identified as parenchymatous toxic of the periphery. The diffuse sclerosis is associated with primary imbecility or idiocy, followed by spastic paraplegia. The commencement of this form has no typical course, but the absence of inflammation in its genesis is noticeable. To this class Merzbach's disease belongs, which he distinguished from sclerosis by being, in his opinion, a family hereditary disease. Its anatomical peculiarity is an intermitting degeneration observed along the axis cylinder of the nerve, and followed by the secondary sclerosis, which Merzbach entitled "aphasia axialis extracorticalis congenita." Pseudo-sclerosis may also be included in this group, as it has all the somatic phenomena of diffuse sclerosis with or without the psychic symptoms, but the tremor is never absent. The histological testimony is in favour of a chemical change in the brain, as there is great absence of fluid in the tissues. The so-called tuberoser sclerosis is only a conglomeration of large cells, probably ganglionic, with increase in the glia locating itself sometimes in the centre, other times on the margin or pendign, but always associated with epilepsy, imbecility or other nervous disturbances. These tumours are usually found on the skin, kidneys, or neighbourhood of the heart. Here again we are bound to recognise this change as a defect in the central system similar to those of the amaurotic idiot. This hereditary form of mental degeneration, with general marasmus and paraparesis, is an affection unknown in the Jewish race, but is undoubtedly a degeneration of the ganglionic cells.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

MEDICAL SERVICE IN THE HIGHLANDS.—The committee which was recently appointed to inquire into the conditions of medical attendance on the inhabitants of the Highlands and Islands of Scotland has held a number of sittings in different localities during August.

It consists of Sir John Dewar (chairman), the Marchioness Tullibardine, Mr. J. C. Grierson, Dr. Leslie Mackenzie, Dr. McVail, Dr. Miller, Mr. Orricks, Mr. Lindsay and Dr. Robertson, Inspector of Schools. At the first meeting in Edinburgh, on August 15th, evidence was given by various officials of Government and other departments which are in touch with the problems at issue. The evidence bore chiefly on the high percentage of uncertified deaths in certain parishes, the heavy rates, the low salaries of the Medical Officers, and the unsatisfactory conditions as to housing and security of tenure. The next sittings of the Committee were in Inverness, where evidence was given by the Medical Officers of Health of the adjacent counties and practitioners in the neighbourhood as to the difficulties of travel in these outlying districts, the inability of the inhabitants to pay fees which cover the time and cost of locomotion, and the consequent disinclination to call in a doctor until absolutely driven to do so. Evidence was also heard from the public authorities, including the Lord Lieutenant of Inverness-shire (the Mackintosh of Mackintosh), and Lord Lovat, which went to prove that the burden of local rates was already almost intolerable, and it was urged that some form of Government subvention was imperative. The large majority of the people in the Highlands were stated to be outside the compulsory section of the Insurance Act, and the question of modifying the weekly contribution so as to make medical benefit available for them was considered. At the next sitting of the Committee the tuberculosis problem was under consideration. Especially in the West, phthisis is one of the chief difficulties in connection with medical attendance, particularly as regards early detection and adequate treatment. Dr. Maclean, Superintendent of the Seaforth Sanatorium, founded by Colonel Stewart Mackenzie, of Seaforth, at a cost of £10,000, suggested that a tuberculosis officer, to co-operate with general practitioners, should be appointed. The majority of cases brought under his notice were too advanced for complete recovery. Further evidence was also given as to the inadequacy, at present, of the medical service in such outlying parishes and glens as Glenmoriston and Lochbroom. At the next sitting, held in Thurso, the same facts were urged: the difficulties in that sparsely populated county being nearly as great as in the more mountainous region of the Highlands. On August 26th the Committee met at Kirkwall to investigate matters in Orkney. Here the difficulties of providing adequate attendance on even comparatively well populated islands, separated by dangerous seas, were discussed. Even when several islands are constituted a parish they seldom can offer adequate salaries, and in addition there are difficulties about houses which make it impossible to retain the services of an efficient doctor for any length of time. The experiment of appointing medical women to these parishes is not satisfactory, as the conditions of practice are too severe. The advantage of having trained nurses, connected with the doctors by a system of telephones, was pressed. Pulmonary tuberculosis is said to be declining in frequency. Less than half the infants born are now vaccinated. The Committee is still occupied in taking evidence, and it can hardly be doubted that the state of matters revealed by its investigations will ensure some more adequate provision being made in the future for medical service in the Highlands.

CHAIR OF PATHOLOGY, UNIVERSITY OF EDINBURGH.—The Curators have appointed Professor Lorrain Smith, occupant of the Chair of Pathology in Manchester, to the Chair of Pathology rendered vacant through the resignation of Professor Greenfield. The appointment has been well received in Edinburgh, where Professor Lorrain Smith is well known and much liked. He is an old Edinburgh student, and was a Resident Physician in the Royal Infirmary under Sir James Affleck, in 1891. He has had a most distinguished career at Oxford, Cambridge, Strassburg and Copenhagen, and previous to his appointment at Manchester he was Professor of Pathology in Queen's College, Belfast. It is not yet known what changes are in prospect in the relation between the holder of the

Chair of Pathology and the Royal Infirmary, but it may safely be said that the department will undergo a complete reorganisation in the hands of the new incumbent of the chair.

CHAIR OF MIDWIFERY, ABERDEEN.—The King has been pleased, on the recommendation of the Secretary for Scotland, to appoint Dr. R. G. McKerron to be Professor of Midwifery in the University of Aberdeen, in place of Professor William Stephenson, who has resigned. Dr. McKerron is 49 years of age, and has been in practice in Aberdeen since 1891. He has for many years acted as assistant to Professor Stephenson, and for five years has acted as Physician to the Maternity Hospital.

BELFAST.

REPORT ON THE HEALTH OF BELFAST.—The report of the Medical Superintendent Officer of Health for the city for 1911 has just appeared this week, and forms a notable advance on previous reports, both as to the matters included in it and the manner in which they are presented. Since Dr. Baillie has been severely criticised in the past, it is only fair to acknowledge the excellence of the present report in most respects. It runs to about 170 pages, and includes some sixty or seventy tables and a good index. The introductory summary gives the population of Belfast as 386,449, the births as 28.4 per 1,000, and the deaths as 17.2 per 1,000. The gradual decline in the birth-rate during the last 31 years is shown in Table 9: it was 35.5 in 1890, and for the last four years has been below 30. Owing, however, to the greatly reduced mortality, the natural increase in population was last year 4,339, the largest it has ever been. Particulars of the death-rate are given in a number of very clear tables, the most interesting and satisfactory being No. 17, which shows the rate for the last four quinquennial periods, beginning in 1892, as 24.6, 22.4, 20.3, and 19.0. There is every indication of a further fall, as the various town improvements have time to produce their effects. Referring to zymotic diseases, an interesting table gives the proportion of these treated at home and in hospital during the past eleven years, and it is astonishing to note the change. The percentage of scarlatina cases treated in hospital has risen from 14 per cent. to 78 per cent., of diphtheria from 23 per cent. to 71 per cent., and of typhoid from 43 per cent. to 84 per cent. Apart from all other precautions, such a change must have an excellent effect on the general health. Typhoid, once the scourge of Belfast, has been greatly reduced of late, and only 85 cases were notified last year. There is good reason to hope that a real decrease in the death-rate from tuberculosis is also taking place. The rate last year was 2.1 per 1,000, while seven years ago it was 3.1. About 700 patients were treated in the wards of the Abbey Sanatorium and the Forster Green Hospital, but if further accommodation were available it could easily be utilised. The question of infantile mortality is considered at length, and many tables are given. It is explained that infantile mortality means the number of deaths of infants under one year old, compared with the number of births registered. Last year it was 128 per 1,000, the lowest for 37 years, except in 1884, when it was 126. The main cause of this mortality is no doubt the employment of the mothers in the mills and factories: after confinement the mother stays at home for about a month, then returns to work, and the child is fed artificially. Under the Notification of Births Act, no less than 6,422 cases were investigated, and upwards of 15,000 visits paid; some were helped by the Municipal Milk Fund, some reported to various charitable societies, and many warned to clean their houses, etc. It cannot be doubted that the effects of these visits will be very far-reaching.

A report by the City Veterinarian on the work of the public abattoir affords some rather startling and unpleasant reading. Tuberculosis in cattle is still alarmingly prevalent, especially in the cows, which are old animals, as a rule. Of these 14,711 were slaughtered in the abattoir, and among them 2,852, or 19.38 per cent. were affected. No less than 235, or 1.59

per cent. were destroyed, as being affected with general tuberculosis, and the remainder were passed after the affected parts were removed. It is not pleasant to think of the meat supply from sources where no careful inspection takes place. The National Schools of the city, numbering some 300, are severely, and justly criticised. Unfortunately the powers of the Corporation authorities are limited in dealing with them, and in very many of them extremely bad conditions prevail. On one subject, on which we have for years past asked information, a strange silence still continues, and that is upon the work of the mysterious refuse destructor erected at great expense. Does it work, and if so, what does it destroy? In most things Dr. Bailie does his best to maintain the good name of the city, but in one thing he is less than just, and that is in his aspersions on our much abused climate. He gives a table, No. 57, of the rainfall for ten years past, showing an average fall of 36.84 inches, but he omits to explain that this is measured on the side of the hills to the west of the city, where the fall is naturally much heavier than in the city generally.

HOSPITAL ABUSE.—At a meeting of the Belfast Medical Guild, held in the Medical Institute on September 5th, the question of hospital abuse was discussed. Many speakers took part, and as usual in such discussions, there was a clearer recognition of the abuse than of the remedy. The best contribution to the debate was made by Dr. A. P. B. Moore, who knew his facts, and had considered them well before he spoke. The members of the hospital staffs professed sympathy with their brethren, but blamed their committees, and specially those on which working men are represented.

THE INSURANCE ACT.—The Belfast papers of Saturday published a long account of the resolutions of the local medical men regarding the working of the Insurance Act, giving the names of all those who have signed the agreement to adhere to the three cardinal points:—Free choice of doctor, wage limit of £2, and payment of 8s. 6d. The names appended number 217, and include practically every man in active practice in Belfast. The document has been sent to the various societies involved, giving notice that all arrangements for contract practice will terminate on December 31, and will only be renewed on these terms.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

PART II. OF THE INSURANCE ACT AS AN INCENTIVE TO MALINGERING.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—A medical man reading the second part of the National Insurance Act will recognise at once that malingering will be increased through its glaring defects.

Had the Committee of the House of Commons who are responsible for the unemployment section of the Act set themselves the deliberate task of devising a legislative measure calculated to suggest and encourage malingering on the part of employees with the connivance at least of their employers, they could not have done more to secure their purpose than that which they have accomplished in this part of the Act.

The unemployment benefit consists in the payment of seven shillings for fifteen weeks during any one period of twelve months. Men under seventeen receive nothing. Those between seventeen and eighteen years obtain three and sixpence during each week of unemployment. Sickness benefit means the payment of ten shillings a week for twenty-six weeks (minors obtaining less, except under certain circumstances).

Employers are entitled to be refunded one-third of their share of contributions paid in respect of an employee who has been for not less than forty-five continuous weeks regularly at work in their "service."

This leaves a margin of seven weeks in each year. Service does not mean employment. An employee may be absent from work without pay, and yet is held to be in service if he is to return to his original employer.

During slack periods an employer might grant his servant leave of absence for seven weeks, without wages and without losing the advantage of retaining the latter in his service for the purpose of the refund mentioned above.

Again, in the case of an employee of sixty years of age, or whose death has occurred after reaching that age, and provided that he has paid not less than five hundred contributions, he, or his personal representatives, shall be entitled to be repaid the amount by which the total amount of his contributions have exceeded the total amount received by him out of the unemployment fund, together with compound interest at 2½ per cent. per annum. This certainly will prove a strong incentive to unscrupulous persons, such as the type malingerers are, to try and substitute the sick benefit of ten shillings a week for the seven shillings provided under Part II. of the Act, and thereby preserve their claims for a large refund at some future date. Part I. does not permit of any similar refund, and the employee forfeits nothing by drawing upon the funds of his Society. (Deposit contributions are an exception in this respect.)

No doubt the vast majority of employers and employees will not be influenced by the opportunities afforded in Part II. of the Act of those of sharp business practices and dishonest natures, I fear, there will be in the future, as in the past, a number who will gladly avail themselves of every defect in an Act to take advantage of such as much as possible.

It is difficult to suggest anything that would prove a check to malingering arising out of the above causes. An honest employer can frequently assist a scrutineer or inspector by giving his opinion of any particular individual's character, but this assistance could not be relied upon in the above cases. Possibly the danger of malingering might be lessened if all employees entitled to unemployment benefit had to state when applying for sick benefit whether they were or were not in actual employment at the time of their becoming invalided, and also if their posts were open to them as soon as they were declared physically fit to resume work.

I am, Sir, yours truly,

SEYMOUR STRITCH.

13 North Frederick Street,
Dublin.

THE TUBERCULOSIS CAMPAIGN IN IRELAND.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In a previous article I outlined a scheme for the establishment of tuberculosis dispensaries with the erection of sanatoria in the coming campaign against the White Scourge. Subsequent reflection has confirmed me in the opinion that the suggestion I then threw out regarding the erection of one large sanatorium for a combination of counties and districts is one that should commend itself to the public. The anxiety displayed by a great many county councils to take an active part in the campaign and discharge the duties devolving upon them in an efficient manner induces me once again to trespass upon your space, and ventilate the conclusions to which I have on mature consideration come. In a complete scheme for the suppression of tuberculosis we must make arrangements for (1) the provision of sanatoria, (2) the establishment of tuberculosis dispensaries, (3) the carrying out of domiciliary treatment.

The education of the public has now reached a high standard through the organisation of the Women's National Health Association, which has been doing such excellent work during the past four years. The passing of the National Insurance Act has brought home to the general public the pressing necessity that has arisen for immediate action, and the funds rendered available through that Act have placed at the disposal of the public bodies the means whereby that

necessity can be largely met; whilst the generosity of the Government in offering large subsidies for the erection of sanatoria, and the promise on the part of the Treasury to meet one-half of the expenditure incurred in the treatment of the disease, have still further placed us in a position of vantage which must be occupied without any immediate delay. The statutory authorities upon whom will devolve the chief work of organisation and administration have thus by education and the grant of financial assistance been presented with the strongest inducements to do their share in the noble work, and the entire public looks forward with hope and confidence to the approaching struggle.

The establishment of a tuberculosis dispensary in every county will form the major part of the organisation. This can be done forthwith, the appointment of a chief tuberculosis officer being the first essential. The officer selected for this post must be one who by reputation and experience and position in his profession can command the confidence and invite the co-operation of his fellow practitioners. His duties will not be confined to the supervision of the dispensary arrangements; he will direct the general treatment and act as consultant and specialist to the general practitioners, who will be entrusted with the domiciliary care and treatment of patients in their own homes. He will also act as superintendent of any sanatorium that is erected by his council, and should be required to act as adviser to the county insurance committee. I regret, however, that the salaries hitherto offered by the majority of county councils are not such as to induce men of proper standing and experience to throw up their present positions and practices and accept these appointments. They will thus fall into the hands of perhaps young men, who may have acquired their experience in the treatment of fifty or a hundred selected cases in small sanatoria, and who are not qualified to act as consultants to men who during the course of their practice have watched the progress of thousands of cases of tuberculosis, and obtained experience of the treatment in all stages of the disease from its earliest development.

With regard, however, to the erection of sanatoria— and this brings me to the chief purpose of this letter— £145,000 have been placed by the Treasury to the credit of Ireland for this specific purpose. Of this sum £25,000 have been placed in the hands of the W.N.H.A. to make temporary provision for the treatment of patients pending the building of permanent structures. The £120,000 is to be allocated to the different county councils in proportion to the population of the county, and the sum thus allocated to each, while fairly large, would only be sufficient to build a sanatorium of very moderate dimensions. Under the provisions of the Public Health (Ireland) Act, 1878, and the Tuberculosis Prevention Act it is permitted to two or more councils to combine and construct a joint sanatorium, but in only two instances has this arrangement been carried out. Now, a very little reflection will show how much more efficient and economical it is to have one large, well-staffed, up-to-date institution, suited to all requirements than a multiplication of several small ones, each with its own administrative organisation and corresponding expenditure. This is self-evident, so that I need not use your valuable space to dilate upon it further. But under the National Insurance Act it is possible to take a further step, and by a still wider combination erect a provincial sanatorium suitable for the requirements of all the counties in a province, and equipped with 200 or 300 beds. Such an institution could be laid out on the lines of the Frimley or Benenden sanatoria in England, or the memorial one to his late Majesty, which is being erected in Wales. Under section 64 (3) the Local Government Board have the power for the purpose of facilitating co-operation to make on their own initiative an order for the establishment of joint committees or joint boards consisting of county councils, county borough councils, or other local authorities (except Poor-law authorities) to carry out the scheme for the provision of sanatoria. Such an order may provide

how, in what proportions, and out of what funds or rates the expenses of providing such institutions, "so far as they are not defrayed out of grants under this section," are to be paid, and may contain such other provisions as appear necessary. The £120,000 used thus for the erection of a provincial sanatorium in each of the four provinces of Ireland would, I believe, do far more for the suppression of tuberculosis in this country than 30 or 40 county hospitals maintaining an independent and unreliable existence. Such institutions would command the confidence of every practitioner in the country, the treatment therein would be of the highest order, and the results proportionate. With one in each province, and a dispensary in each county under the charge of a capable and experienced tuberculosis officer, the general body of practitioners who, as the main fighting units, would carry out the domiciliary treatment of the patients in their own homes, could be relied on to do their part in stamping out the disease.

I am, Sir, your truly,
SAMUEL AGNEW.

Lurgan, September 2, 1912.

"ANOTHER RESIGNATION."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—You will regard my contributions as a "standing dish"; I assure you, however, that such is not the case. If you continue to publish matter so stimulating to reflection, I feel it my duty to respond, lest from lack of enthusiasm on the part of your readers you fall from your high estate. "A Resignation from the B.M.A.;" this title at once arrests our attention. Such a calamity 12 months ago would not have been recorded, but a great many things have happened during the last year. Mr. Lloyd George has launched his little ewe lamb, jealously safeguarding its career by stopping the mouth of any gainsayer, and pointing out its future possibilities in order to hide its present hideousness. It has been duly christened disendowment of the medical profession, vote catcher; and it has been registered as an Act. Unfortunately it has already belied its name, it certainly is not a vote catcher, and the medical profession refuses to be disendowed. Already, therefore, this marasmic infant is under a cloud. Your cheery optimism, Mr. Editor, has been replaced by pessimism. You regard the resignation of Dr. Forbes as ominous. One swallow does not make a summer, one black sheep does not contaminate a whole flock. So, cheer up, there are very many men in the profession who are not M.O.H.'s, and who have not any chance of being appointed tuberculosis officers, even if they wished for such an appointment. Men who are general practitioners, who have been aptly termed the backbone of the profession, who owe nothing to this or any other Government, but to whom each Government in turn owes a debt which it can never repay. These are the men most concerned in the working of the Insurance Act. I should be far more depressed if I read of the resignation of one of the G.P.'s of Manchester. Then I should wonder whether we were beginning to suffer from osteomalacia—but not yet! Besides our profession there are many other bodies who doubt the benefits which are supposed to flow from this Act. Think of the 17,000 in Birmingham, who are withstanding the generous offer of 9d. for 4d. Think of the farmers of Beds. and Bucks, and take heart! We are not the only unbelieving Thomas's.

I am, Sir, yours truly,
S. J. ROSS.

Bedford, September 9th, 1912.

OBITUARY.

MR. L. A. BIDWELL, OF LONDON.

It is with the deepest regret that we have to record the death of Mr. Leonard Arthur Bidwell, F.R.C.S., Senior Surgeon to the West London Hospital and Dean

of the West London Post-Graduate College, which took place on the 2nd inst., consequent upon an operation for appendicitis, at the age of 47. Educated at Blackheath School, Mr. Bidwell, who was the son of a former chief clerk in the General Post Office, received his medical training at St. Thomas's Hospital and in Paris. He qualified as L.S.A. in 1886, M.R.C.S. in 1887, becoming F.R.C.S. in 1890. To say that he will be sorely missed at the West London Hospital is but feebly to express the truth, for Mr. Bidwell was the very life and soul of the post-graduate college connected with the institution. All his best energies were devoted whole-heartedly to the interests of the College, which, largely owing to his untiring efforts, has attained a position of the first rank as a post-graduate centre of instruction, its high level of efficiency being fully recognised by the Government medical services. As Dean of the College and Lecturer in Intestinal Surgery therein, Mr. Bidwell commanded the respect and won the affections of all with whom he was brought into contact. He was President of the Chelsea Clinical Society, Surgeon to the Hospital for Invalid Ladies, Lisson Grove, and Consulting Surgeon to the City Dispensary and to the Blackheath and Charlton Hospital. He was also a Medical Referee under the Workmen's Compensation Act and Surgeon-Major in the Royal Bucks Hussars, Imperial Yeomanry. His book on "Intestinal Surgery," a subject on which he was an authority, has already established for itself a well-deserved reputation, and his "Minor Surgery" was published last year. Mr. Bidwell married Dorothea, the eldest daughter of Sir Roper Parkington.

DR. G. GARLICK, OF LONDON.

We regret to record the death of Dr. George Garlick, of Gordon Square, Bloomsbury, and Heathfield, Thakeham, Pulborough, Sussex, which took place last week at Worthing, as the result of an accident. The deceased, who was educated at University College, London, became M.R.C.S. Eng. in 1874, and L.R.C.P. in the following year, taking the M.D. Lond. in 1876. Dr. Garlick was Medical Referee of the Teachers' Provident Society, and formerly Registrar of the Hospital for Sick Children, Great Ormond Street. He was also Clinical Assistant at the Consumption Hospital, Brompton, and held an appointment at University College Hospital. He devoted special attention to the treatment of children's diseases, and contributed to medical publications "Ophthalmoscopic Observations in the Tubercular Meningitis of Children," "Tubercular Peritonitis in Children," and other articles, including one on "A Case of True Diaphragmatic Hernia."

SURGEON-MAJOR KENDALL.

The death took place last week, at 8 Harold Road, Upper Norwood, at the age of 81, of Surgeon-Major Bernard Kendall, a survivor of the Indian Mutiny. Surgeon-Major Kendall married, 1855, Barbara, the daughter of Captain Lucas, of the Hon. East India Company. At that time he was Assistant Surgeon in the service of the Company. Later he was appointed Assistant Surgeon in the General Hospital at Calcutta and at the Fort, and in 1857, when the Mutiny broke out, was stationed with the 2nd Oude Infantry at Secroora, about 50 miles from Lucknow. He remained with the regiment until it mutinied, when he escaped with Sir Charles Wingfield and other officers. Mrs. Kendall had previously gone into Lucknow with the other women and children. Surgeon-Major Kendall remained in the Indian Medical Service for 21 years and then retired.

REVIEWS OF BOOKS.

THE CAUSE OF CANCER. (a)

The late Sir Henry T. Butlin once stated that three requirements were necessary in an individual before

(a) "The Cause of Cancer, being Part III. of 'Protozoa and Disease.'" By J. Jackson Clarke, M.B., F.R.C.S., Senior Surgeon to the Hampstead and North-West London Hospital and Surgeon to the Royal National Orthopaedic Hospital. Fep. 4to. Pp. xii., 112. London: Bailliere, Tindall and Cox. 1912. Price 7s. 6d. net.

he could lay claim to speak with any authority upon the subject of cancer, a knowledge of the protozoa, experience of experimental investigation of cancer, and experience of the clinical pathology of cancer in the human subject. The author of this book certainly fulfils these requirements, so that his views on malignant disease are entitled to serious consideration, not only by public bodies competent to weigh evidence in a scientific fashion, but also by every practitioner of medicine to whom the question of cancer is a subject of interest. The reader will find, plainly stated, the evidence from which Mr. Jackson Clarke deduces the protozoic origin of the commoner forms of cancer, and the report of the Morbid Growths Committee of the Pathological Society of London in 1893, upon his labours is critically examined. The author's reply, published, with his account of cancerous disease, first in THE MEDICAL PRESS AND CIRCULAR, September 30, 1893, is added in the form of an appendix. An earnest plea is made for the careful reconsideration of his work and of the relations of the protozoa to cancer by such a body as the Imperial Cancer Research Fund. The work of this Fund, in the opinion of the author, has been lacking because he has not seen any evidence that "any of the workers have made a special study of the protozoa" in their relationship to malignant disease. The time may yet arrive when the merits of Mr. Jackson Clarke's researches will receive their due recognition, and in the end it may prove that "the protozoa are deadlier enemies of man even than the bacteria."

SAVILL'S CLINICAL MEDICINE. (a)

THE appearance of the third edition of this excellent manual will be welcomed amongst a large circle of medical readers with whom the book has been from the first deservedly popular. Owing to the death of the author by a lamentable accident, the task of editing the present edition has devolved upon his wife, Dr. Agnes Savill. The task of bringing the book up to date has been well and conscientiously performed, and fully sustains the progressive reputation already gained. One secret of its attractiveness is to be found in its careful condensation, whereby the wide subject of clinical medicine is dealt with in the space of a single volume of something under 1,000 crown octavo pages. The medical practitioner will find here a clear account of most of the points as to which he is likely to need a reference. For the senior student reading for the higher examination it would be difficult to imagine a more generally useful volume. The late author's position as Examiner in Medicine enabled him to bring out leading and neutral points in clear perspective—a gift that comes more or less naturally to the ideal examiner. Dr. Savill's special work as a dermatologist and a neurologist is reflected in the conciseness with which both these subjects are dealt with. In the present edition Mrs. Savill has secured the revision of various well-known authorities in several of the sections. Such names as those of Dr. Ford Caiger, Dr. F. M. Sandwith, Dr. Leonard Williams, Dr. Angus MacGillivray, Dr. R. H. Cole, Dr. Harry Campbell, Dr. L. Garrett Anderson and Dr. Frederick Langmead appear on the list. Two polygraph tracings of the heart have been contributed by Dr. James MacKenzie; and Dr. Gordon B. Ward has contributed a chapter on diseases of the blood. The general turnout of the book is excellent, and the coloured illustrations reach a high level of technical excellence.

THE EXTRA PHARMACOPEIA. (b)

THE fifteenth edition of this well-known work has just appeared, and the publishers have found it neces-

(a) "Clinical Medicine: A System of." By Thomas Dixon Savill, M.D. London: Third Edition, revised by Dr. Agnes Savill. London: Edward Arnold, 1912. Price 25s. net.

(b) "The Extra Pharmacopœia." By Martindale and Westcott. 15th edition in 2 volumes. Fcap. 8vo. Vol. I. xxxi., 1,114. Price 14s. net. Vol. II. viii., 370. 1912. London: H. K. Lewis. Price 7s. net.

sary to issue it in two volumes owing to the immense growth of the subject matter during the last two years. In spite of the division, however, the size of the first volume has been kept down to practically that of the last edition. This portion of the work contains, in addition to the complete pharmacopœia of official remedies and all the principal non-official chemicals and drugs with their properties, modes of administration, and references to current literature, valuable chapters on vaccinotherapy, the Poisons and Pharmacy Act, and a comprehensive therapeutic index of diseases and symptoms. The general posological index referring to the two volumes, contains some twelve thousand headings. Briefly to indicate only a few of the new or enlarged features of this volume, we may mention the twenty-five pages devoted to salvarsan; the methods of spinal anæsthesia; anserine mulls; iontophoresis; tuberculin administration; and the newer cell-proliferants.

The second volume, one-third of the size of the first, contains analytical memoranda, bacteriological notes, an account of home and foreign mineral waters, glossaries, and an organic analysis chart. A succinct analysis of patent medicines is given, and there is a note upon the Select Committee upon patent and proprietary medicines which met for the first time on May 9th, 1912. In this volume standard bread is introduced, and some new data are given with regard to beri-beri and leprosy. The salient features of the last annual report of the Imperial Cancer Research Fund are also given and some recent diagnostic methods are described.

To say that the "Extra Pharmacopœia" is a mine of information is feebly to express the truth. It is rather a never-failing treasury, whose inexhaustible stores are all-sufficient to meet the demands of the most exacting inquirers as well as to satisfy the needs of the humblest seeker after therapeutic truth. No practitioner should remain a single day without possessing a copy.

THE MEDICAL ANNUAL. (a)

THE reviewing of Wright's *Medical Annual* is always a pleasant task. Whatever may be his interests, the reader is sure to find them roused in turning over its pages. The anonymous editors, as usual, do not content themselves with merely giving a *résumé* of the year's work in the various fields of medicine and surgery, but they include special articles of much detail on certain subjects. The most noticeable of these articles in the present volume is that on salvarsan. The author treats fully of the method of administration and the toxicology of this drug, and its uses in syphilis and in other diseases. His tone is cautious throughout, and the author maintains that "Ehrlich's hope of curing the disease by a single administration of the drug has proved fallacious." He believes, too, that salvarsan has made nerve relapses more common.

The article on vaccines is disappointing, considering the interest generally felt at present in this method of treatment. A good deal of space is taken up with the description of a mixed and modified vaccine of the blunderbuss type, made from growths of seven or more organisms, and to be used in infections of unknown cause! It is this sort of thing which excites the prejudice still felt against vaccine treatment in certain quarters. We hope that the editors will next year see fit to give adequate consideration to this important subject.

Many readers will turn with interest to the article by Dr. Bedford Pierce on psycho-analysis. He gives a summary of recent work on the subject, but sets forth fairly the dangers which possibly lurk in the method. He seems to regard it as of more utility in diagnosis than in treatment.

Space forbids us to deal with more of these articles. No one can turn over the pages of the book without

finding much that is both interesting and instructive. Every general practitioner should make it his duty to study the volume with care, and even the specialist who reads the pages dealing with his own line of work will not waste his time. We congratulate the editors on keeping their volume for 1912 up to the high standard of its predecessors.

MEDICAL NEWS IN BRIEF.

A New Hospital for Women.

A MOVEMENT has been set on foot to add to the number of hospitals which admit women on their honorary staffs, and a strong committee, including, among others, Lady Chance, Miss Chadburn, M.D., the Hon. Mrs. Franklin, and Miss Davies-Colley, M.D., F.R.C.S., has been elected. It is proposed to erect the new women's hospital in South London, and that it should consist of an in-patient department, with (1) general wards and (2) private wards, the latter being intended for women of small means who cannot afford medical attention in a nursing home and yet should not be occupying the free wards intended for the very poor in ordinary hospitals. These private wards will be provided for patients paying at an inclusive rate of from one to three guineas a week. There will be a well-staffed out-patient department with a woman almoner or inquiry officer. A site has already been secured, consisting of three acres of freehold ground with a large frontage on Clapham Common. The out-patient department is separate, and will be situated in the main thoroughfare near the termini of the great southern railways. It is hoped that this department will be opened in the autumn. The scheme is being loyally supported by medical women and by those interested in the woman movement, including Mrs. Garrett Anderson, M.D., the Lady Robert Cecil, the Lady Cowdray, Sir Bryan Donkin, F.R.C.P., Sir James Goodhart, M.D., F.R.C.P., Miss Hamilton, M.D., the Bishop of Kingston, Lady Roberts, Mrs. Scharlieb, M.D., the Bishop of Southwark, the Lady Templemore, Miss Jane Walker, M.D., the Bishop of Winchester, and many others.

Death of a Pioneer Woman Physician.

AT the age of 78, Dr. Sarah F. Wells, one of the first women physicians of the United States, has recently passed away in her native State of Ohio. Dr. Wells spent a considerable portion of her life in Turkey and India, being the first qualified woman physician to be appointed to a harem in Turkey. She also devoted many years of her career to securing proper medical treatment for the Indian women and children, and stirred the public conscience on their behalf by giving lectures in the large cities in India.

Sad Death of a Medical Man.

THE body of Dr. Alfred Harris, recently appointed Tuberculosis physician for Swansea and district under the King Edward Memorial scheme, was found dead in bed at one of the leading Swansea hotels last week. The deceased had been staying at the hotel since Tuesday prior to taking a house. It is believed he had taken an overdose of morphine. Dr. Harris, who came to Swansea from the Municipal Sanatorium at Shirley, Southampton, had had a brilliant career, being M.D., Ch.B., and D.P.H. At the inquest it was stated that prussic acid, in addition to morphia, was the cause of death. The usual verdict was returned.

School Clinics at Newport.

AT a recent meeting of the Monmouthshire Elementary Education Committee the question of school clinics was again discussed. The recommendations of the Committee were adopted. Altogether there will be 15 clinics, engaging four nurses, one whole-time ophthalmic surgeon, and one whole-time dental surgeon. The initial outlay will be £11,000, and annually the upkeep will cost £2,000.

(a) "The Medical Annual: A Year Book of Treatment and Practitioner's Index." 1912. Thirteenth year. Pp. cxx. and 887. Bristol: John Wright and Sons, Ltd. Price 8s. 6d. net.

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature* or *Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8 Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

NOTICE TO HOSPITALS AND COLLEGE DEANS.

THE Editor wishes to thank the above gentlemen attached to the various Schools and Hospitals for supplying him with the information from which the foregoing pages have been composed.

NOTICE TO OUR READERS.

As this number is mainly devoted to information necessary for students intending to join one or other of the various medical colleges, and for those who, having passed their curriculum, are about to enter the ranks of the profession, much of the ordinary matter which usually fills our columns is necessarily deferred till next week.

GRATUITOUS COPIES.

A VERY large number of copies of this issue are being sent gratuitously to all the educational establishments, hospitals, reading-rooms, clubs, and large hotels in the United Kingdom, and to a large number in America, India, the Colonies, and on the Continent; should any of our readers desire to present a copy to a patient or friend who contemplates sending his son to a medical school, our publisher will be happy to supply him with a duplicate free of cost on receipt of address.

F.R.C.S. EDIN. (Beds).—Electrolysed fluid for disinfecting purposes has been in use for the last six years by the Poplar Borough Council, the annual cost last year being about £100 for the manufacture and distribution of 55,000 gallons. It forms a cheap, clean, and efficient chlorine solution which may be recommended for most purposes where this form of disinfectant is favoured.

COMMON SENSE COOKERY.

A SERIES of lectures has been organised by the secretary of the Society of Medical Officers of Health on "Common Sense Cookery in Health and Disease." The lectures are designed to assist the work of fighting consumption in the homes of the poor, for whom the knowledge of the preparation of cheap and appetising meals is not only an economic but an important hygienic consideration.

THE MEDICAL HERB CROPS.—It is reported that English growers of peppermint, lavender, and other medicinal herbs have suffered serious loss from the recent rains. In all cases crops are considerably below the average, and in some instances growers report that the crops will be the smallest on record.

WORKMEN'S COMPENSATION ACT, 1906.

THE Home Secretary gives notice that in consequence of the resignation of Mr. James Mungle, the appointment of Medical Referee under the Workmen's Compensation Act, 1906, for the Dunfermline with Kinross District is now vacant. Applications for the post should be addressed to the Private Secretary, Scottish Office, and should reach him not later than the 27th September.

THE HISTORY OF AMBULANCE.

MEDICAL men engaged in teaching first aid and ambulance will find Mr. Charles H. Miles' little brochure on "An Historical Outline of Ambulance from the Earliest Times" (Bristol: John Wright and Sons, 3d. net) both interesting and instructive. A brief sketch is given of the art and practice of ambulance from the times of the ancient Greeks to the foundation of the St. John Ambulance Association in 1877.

Appointments.

BUTCH, A. G., M.B., Ch.B. Vict., House Physician at the Manchester Royal Infirmary.
JEFFERSON, J. C., M.B., Ch.B. Vict., Senior House Surgeon at the Manchester Royal Infirmary.
MACKLIN, A. H., M.B., Ch.B. Vict., House Physician at the Manchester Royal Infirmary.
MIDDLEY, P. H., M.B., Ch.B. Vict., Junior House Surgeon at the Manchester Royal Infirmary.
MOLAN, CORNELIUS, L.R.C.S. Irel., Junior House Surgeon at the Stockport Infirmary.
RADCLIFFE, FRANK, M.B., Ch.B. Edin., Assistant House Physician at the Devonshire Hospital, Buxton, Derbyshire.
SAYILL, AGNES F., Assistant Physician to the London Skin Hospital, Fitzroy Square.

SAWDON, G. E., M.B., Ch.B. Vict., Senior House Surgeon at the Manchester Royal Infirmary.
SEPFELT, NORBERT E., L.R.C.P. and S. Edin., Junior House Surgeon at the Stockport Infirmary.
THOMPSON, H. HYSLOP, M.D. Glasg., Medical Officer under the King Edward VII. Welsh National Memorial Scheme.
VINCENT, W. H., L.M.S.S.A., House Surgeon at the Evelina Hospital for Sick Children.
WHITAKER, H., M.B., Ch.B. Edin., House Surgeon at the Stockport Infirmary.

Vacancies.

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointment:—Long Sutton (Lincs.).
Royal Victoria Eye and Ear Hospital.—Two House Surgeons. Salary £40 per annum with board. Applications to the Hon. Secretary, Adelaide Road (see advt.).
Birkenhead Borough Hospital.—Senior House Surgeon. Salary £100 per annum, with board and laundry. Applications to the Secretary at the Hospital.
Powick (Worcester) County and City Asylum.—Junior Assistant Medical Officer. Salary £160 per annum with board, furnished apartments, washing, and attendance. Applications to Medical Superintendent.
The Royal Infirmary, Hull.—Senior House Surgeon. Salary £150 per annum, with board and furnished apartments. Applications to Chairman, House Committee.
Royal Isle of Wight County Hospital, Ryde.—Resident House Surgeon. Salary £100 a year. Applications to the Secretary.
The Royal National Hospital for Consumption and Diseases of the Chest, Ventnor.—Senior Resident Medical Officer. Salary £250 per annum, with board and lodging in the Hospital. Applications to the Secretary, 13 Buckingham Street, Strand, London, W.C.
Stirling District Asylum, Larbert.—Junior Assistant Medical Officer. Salary £140 per annum, with board, lodging, and laundry. Applications to the Medical Superintendent.
Dundee District Asylum.—Junior Resident Medical Officer. Salary £120 per annum, with board and apartments. Applications to Robert Allan, Clerk, Dundee District Board of Lunacy, Chambers, West Bell Street, Dundee.

Births.

BENNETT.—On Sept. 1st, at Staverton, 35 Vancouver Road, Forest Hill, S.E., the wife of Colin E. Bennett, M.R.C.S., L.R.C.P. Lond., of a son.
CURWEN.—On Sept. 1st, at The Elms, Frome, Somerset, the wife of H. Curwen, M.B., Ch.B., D.P.H., Medical Officer Zanzibar Government, of a son.
HARRISON.—On Sept. 1st, at The Priory, St. Neots, the wife of Ernest H. Harrison, M.A., M.D. (Cantab.), of a daughter.
O'GRADY.—On Sept. 5th, at No. 1 Merrion Square, Dublin, the wife of Major Standish de C. O'Grady, R.A.M.C., of a son.

Marriages.

COOMBS—MILNE.—On Sept. 4th, at All Souls', S. Hampstead, Percival Charles Coombs, M.R.C.S., L.R.C.P., of the Surrey County Asylum, Brookwood, to Susie May, daughter of the late David Braick Milne, of Liverpool, and of Mrs. Milne, of Belsize Crescent, Hampstead.
COWELL—MILLER.—On Sept. 3rd, at Holy Trinity Church, New Barnet, Ernest Marshall Cowell, M.D. Lond., F.R.C.S. Eng., to Dorothy Elizabeth, only daughter of Arthur and Christiana Miller, of Lime Hurst, New Barnet.
DOBSON—KING.—On Sept. 4th, at St. Olave's Church, London, Maurice Rowland Dobson, M.B., B.S. Lond., L.R.C.P., M.R.C.S. Eng., younger son of Jabez Dobson, Woodbank, Ilkley, to Ethel May King, granddaughter of the late William Wells King and Mrs. King, of Malton.
LIPSCOMB—MILMAN.—On Sept. 7th, at St. Albans Abbey, Eustace Henry Lipscomb, M.B. Cantab., J.P., of St. Albans, to Mildred Charlotte, fourth daughter of the late Lieut.-Colonel Everard Stepany Milman, R.M.A.
NESFIELD—BAIRD.—On Aug. 31st, at All Saints' Church, Norfolk Square, London, W., Capt. V. B. Nesfield, I.M.S., son of J. C. Nesfield, M.A. Oxon., of Ealing, Middlesex, to Grace Baird, daughter of the late Dr. J. T. W. Baird, of Congleton, Cheshire.
SECCOMBE—LANG.—On Sept. 5th, at Egguckland, Captain J. W. Seccombe, R.A.M.C., eldest son of Paymaster-in-Chief J. W. Seccombe, R.N., and Mrs. Seccombe, of Southsea, to Beatrice Martha, second daughter of the late Captain H. B. Lang, R.N., and of Mrs. Lang, Hartley Avenue, Plymouth.

Deaths.

COVEY.—On Aug. 31st, Edward Charles Covey, M.R.C.S., L.S.A., of Alesford, Hants, aged 71.
COX.—On Aug. 28th, at Corsham, Wilts, Fleet-Surgeon A. H. Lissant Cox, R.N.
KENDALL.—On Sept. 3rd, suddenly, at "Secrora," 8, Harold Road, Upper Norwood, Bernard Kendall, Surgeon-Major, Retired List I.M.S., aged 81.

DR. THOMPSON lately returned from Cordoba, Argentina, is requested to communicate by letter, with "A.B." c/o., H. Green, 120 Chancery Lane, E.C.

NOTES AND COMMENTS.

An Over-burdened Medical Officer of Health.

THE acceptance of the superintendency of the Brighton Sanatorium by Dr. Duncan Forbes opens up a question of public importance, apart from its bearing upon internal professional politics. If Dr. Forbes is prepared to withdraw from his pledges and to flout the opinion of an overwhelming majority of medical men, it is to be hoped that his shoulders will be broad enough to bear the burden he has apparently assumed in so light a fashion. Time will settle that aspect of the affair; but there is another which demands the thoughtful attention of all interested in the responsible administration of public health. Of late years, as everyone knows, the duties of the medical officer of health have been greatly multiplied. The control of infectious disease, the medical inspection and care of school-children, health visitation, the control of milk supply, and advances in many other directions have entailed a great amount of additional work on that officer. In any large centre of population, it may be asserted without hesitation that the duties of his responsible post are enough—and, as a rule, more than enough—to occupy the energies of any one man, who, be it remembered, has also to keep abreast of current scientific advances in his branch of special work. Under such circumstances, is it possible for a busy man to undertake the control of a sanatorium full of consumptive patients? If he is to look after sick folk effectually, he cannot devote much time to the discharge of the multifarious duties of his office and *vice versa*. The ratepayers cannot have it both ways. If they make a dual appointment of the kind that has found favour with the Brighton authorities, they must seriously handicap either their public health or their sanatorium service. To saddle one man with two heavy burdens of that kind is to repeat the folly which in the past has rendered contract medical work a conspicuous failure—namely, to strike a bargain for service which it is physically impossible for any one man efficiently to render.

Death After Tooth Extraction.

At a Bethnal Green inquest last week a qualified chemist was censured for not having kept his tooth-extracting instruments clean. The incident deserves wide notice for various reasons. The facts disclosed in court were that deceased, a girl, 22 years of age, went for a visit to Margate, where she had a tooth extracted by a local chemist. Her mouth swelled, and on her return

home, after visits to two private medical men, she went to the London Hospital, where a second tooth was extracted, and she was sent to the infirmary. A few days later she left the latter institution against the doctor's wishes, and died three days later. The inevitable deduction from this account is that of general sepsis following the removal of a tooth. The details of the causation, however, are by no means clear. It was alleged that the chemist kept his instruments in brown paper, and did not clean them before use; but he himself declared that he "usually" boiled his forceps in carbolic lotion after use, and "often" used an antiseptic before operation, but could not say he did so in that particular case. He kept them in chamois leather. The medical evidence was of the kind one would expect under such circumstances. A medical witness remarked "if a girl's mouth were septic, the taking out of the tooth might have caused the trouble." At the wish of the jury the coroner severely reprimanded the chemist for not having kept his instruments clean. As the jury had the whole evidence before them, it is likely they had sufficient grounds for that opinion. As regards the local infection, clearly it may have arisen either from septic instruments or from a previously septic oral condition complicating the operation. In either case, the deplorable result would in all probability have been avoided by a skilful expert. At any rate, operation under such circumstances by an unqualified dentist is undesirable in the interests of the public, for it subjects the patient to avoidable risks of the most serious nature. In a word, it defeats the whole aim and object of the Dental Acts.

Unqualified Dental Practice.

THE intention of the Legislature was to protect the public against the practice of dentistry by ignorant and unskilled persons. It is based on the fact that dental science has reached a high pitch, and to be competent in its practice it is necessary to be educated in anatomy, physiology, the principles of medicine and surgery, and to possess a great amount of mechanical and technical skill and training. For a man without the requisite qualifications, as obtained by examination and vouched for by a State diploma, to deal with a septic mouth is to court disaster. Why, then, is not the highly desirable statutory protection of the safety of the citizen afforded by the Dental Acts supported by the corollary of the suppression of the quack? Why, indeed? And why is he not similarly protected against the medical quack? The pith of the present position is that the Dental Acts are a dead letter. It is open to every ignorant person to set up as a dentist, and there is no one to stop him doing so. The Penal Committee of the British Dental Asso-

ciation is not only impotent, but to such an extent are their hands weakened by the facilities open for unqualified practice that it is only with difficulty they are able to keep up a show of discipline in the ranks of the duly qualified practitioners. The latter find themselves terribly handicapped in the battle of professional life. After a long and expensive education, they are called upon to compete with an army of unqualified charlatans, who attract patients by every sort and species of advertisement, which, of course, cannot be used by the qualified dental surgeon. The present position is preposterous and absurd. It is infinitely worse than the state of affairs before, inasmuch as the number of quacks has increased a hundredfold. So far as the qualified chemists are concerned, it is a pity that members of an honourable body should be found engaging in a task which the Legislature has decided should, in the interests of the public, be handed over to a special trained class of men. The better kind of qualified chemist has long since abandoned the extraction of teeth.

Law for Lawyers and Law for Doctors. At a London police-court last week was once more illustrated the efficiency of penal clauses of the Acts which regulate the profession of solicitor. A solicitor's clerk was fined £10 and costs for "counselling and procuring" a qualified solicitor to perform some trivial legal service for him. It appeared that the solicitor in question, who was ordered to pay a nominal penalty of 10s., had not renewed his certificate, and his name was temporarily off the rolls. The Law Society being informed instituted the prosecution. When will similar powers to enforce similar laws be conferred upon the General Medical Council? At present the most fraudulent of unqualified quacks can assume the title Dr. with impunity; and not only may a qualified man practice when unregistered, he may with impunity go on practising and using medical titles after his name has been struck off the Register for infamous conduct of any degree of gravity.

Johne's Disease. THE name of John's disease, although familiar enough to farmers and stock owners, who have been great losers from it, is probably unknown to the average medical reader. It has hitherto been impossible to diagnose the malady until so far advanced as to render the affected cattle useless for breeding or milch purposes, and of very little value to the butcher. The flesh of animals suffering from the disease is not unfit for human consumption, but in the later stages emaciation becomes extreme, and the carcasses practically lose all value. Early diagnosis of the disease would prevent this loss, and it is now stated that Mr. F. W. Twort, M.R.C.S., and Mr. G. L. Ingram, M.R.C.V.S., of the Brown Institution, have just obtained a diagnostic reagent which will effect this purpose. This reagent injected subcutaneously causes a rise of temperature of from $4\frac{1}{2}$ to $5\frac{1}{2}$ degrees Fahrenheit in an animal in which the disease exists, but does not affect the healthy. As so often happens in similar instances where a national service is performed, the work has been paid for from virtually private endowments, not by Government. In the present case the Royal Society and the Trustees of the Henry Dixon Fund have found the money. The Development Fund Commissioners, we are told, were twice asked for a grant of £1,000, which each time was refused.

LEADING ARTICLES.

CERTAIN ECONOMIC POINTS IN MEDICAL PRACTICE.

RECENT events in the medical world have given rise to a more generally critical attitude with regard to its collective interests. Whatever may be the outcome of the present dispute, it has brought home to medical men an intense conviction of the value and the necessity of professional unity. For many years past it has been a commonplace amongst a certain class of medical writers to deprecate the introduction of the spirit of trades unionism amongst the members of the profession. Such views were for the most part uttered by men who had never come into contact with the conditions of practice amongst the poorer classes of the community. Had any general and effective combination existed for the defence of the collective interest of medical men been in existence, it may be safely asserted that the gross evils of abuses of contract medical practice would never have attained the rank growth which characterised them at the time of Mr. Lloyd George's insurance legislation. With the experience of the Insurance Act still galling their shoulders, medical men are reminded that on previous occasions the Legislature has taken advantage of an unorganised profession and thrust upon it the burden of unpaid, yet responsible, service. A standing instance of that kind is the death certificate, which must be signed by the medical practitioner under pains and penalties, but which he is compelled to furnish free of cost. The certificate thus issued by him, it must be borne in mind, constitutes a weighty official document, upon which important issues of descent, inheritance and identification may depend. So important to the community is the principle therein involved, that we find dating from the early days of the Norman dynasty the important office of coroner. Where medical testimony is not forthcoming, it is the duty of the holder of that judicial position to inquire into the cause of death, with the help of a jury. In spite of this. State recognition of the vital necessity of identification of bodies and systematic supervision of the cause of death, it provided no fee when, at a later date, the further safeguard of the judicial death certificate was introduced. The medical practitioner from whom the vital part of the document, that is to say, the signature, was demanded, was awarded no fee for his service. So deeply-rooted, indeed, appears to be the attitude of Parliament with regard to the sweating of medical men, that when Mr. Burns brought in his measure for the Early Notification of Births, not only was no fee allowed for the certifying medical attendant, but he was rendered liable to imprisonment if he neglected to furnish the certificate. Manchester has lately adopted that particular Act, and its medical practitioners accordingly become subject to the penal clauses of the Early Notification of Births Act. The situation thus created, as one can readily imagine, is not likely to

be stomached by men of the Manchester temperament and more is likely to be heard about the matter. The events of the last few years with regard to the insurance legislation have illustrated the deeply-grained parliamentary habit of sweating the medical profession to the utmost limit. With the medical benefits of the Insurance Act coming into force in January next—that is to say, within the brief space of three and a half months—no satisfactory agreement has been arrived at with regard to the terms offered to medical men. The original bargain offered by the Chancellor of the Exchequer has been contemptuously rejected by the profession. The Government appear to be resolved, on their part, to maintain a sullen silence, and the question has been freely mooted in the newspapers whether there will be enough "blacklegs"—as the phrase goes—to enable Mr. Lloyd George to go behind a hostile profession. The situation thus disclosed is remarkable, and it says much for the mental robustness of a politician who, in view of the comparatively near approach of a General Election, can thus lightly alienate the sympathies of a great and powerful profession, which, by the nature of its work, is brought into daily and hourly contact with all classes of the community, and which regards the conditions imposed upon medical men under the Act with a sense of rankling injustice. Whatever be the upshot of our collective protest, we trust that members of the hospital staffs will not permit their good nature to be imposed upon by the Government. Large numbers of insured persons are certain, as heretofore, to flock to the voluntary medical charities for the treatment of every possible kind of malady. No provision whatever has been made for payment of the medical men whose services are given gratuitously to those institutions. There is one point on which they may enter a strong and effective protest—namely, by refusing to sign any certificate for any hospital patient required for the purposes of the Insurance Act, unless an adequate fee is forthcoming for every such document. The unpaid medical certificate has had its day. It rankles now as a solid grievance that birth, death, and many sickness and other certificates carry no fee. It is indefensible that the State should take advantage of overworked members of honorary hospital staffs to extract from them without fee certificates essential for administrative purposes. On this point of refusal of unpaid certificates, at any rate, it may be hoped that hospital consultants and specialists will be clear, united and emphatic.

CURRENT TOPICS.

The Future of Medicine as a Profession.

THE future is a subject about which there can be a considerable and legitimate difference of opinion, and some of the members of the medical profession share with a proportionate number of the members of other learned professions the belief

that the best days of professional prosperity are passed. Life differs from logic in that it is difficult to argue from premises unless the conclusion is known, and as yet the conclusion lies in the years ahead. Impelled by a sense of stern duty to parents and students, a prominent Irish surgeon has addressed a letter to the press pointing out that as a result of the Insurance Act Irish students will no longer be able to obtain lucrative practices in England. Between two and three hundred medical men qualify in Ireland each year, and of these not more than half are likely to obtain Government employment. Those who go to England will find that all the industrial workers will be enrolled under other practitioners for insurance purposes, and they will not be able, therefore, to obtain a footing. On the other hand, if free choice of doctor is permitted every three months, there is always a good chance of a new doctor being chosen. Moreover, patients do not always wish to go to the club doctor, neither can they be expected always to stick to the practitioner first chosen. We fail to see that the Insurance Act will cause a great change in the prospects of Irish doctors in England, certainly not a sufficient change to warrant us cutting off the supply of students to any great extent. The new Act must, however, interfere with the sale of practices, and when practices become non-transferable, there will be an opening for the new man. Few people ever consider medicine as a money-making profession, and if the Insurance Bill has not made it more lucrative it cannot be held as yet that it has made it less.

The Persistence of Racial Characteristics.

By the study of any given characteristic, be it mental or physical, we tend to throw some light on the general subject of heredity, and to add another fundamental principle to the science of eugenics. Several papers have been published recently in the *New York Medical Record* on the persistence of certain racial characteristics in the distant offspring of white and coloured people. Kintzing came to the conclusion that there is no positive sign whereby a much diluted strain of negro blood may be discovered. It has long been held that the offspring of even the most attenuated mulatto and a pure white always has some trait, such as a peculiar distribution of pigment around the genitalia, or some peculiarity of the finger nails, which reveals itself to the expert. The conclusions published by Kintzing are interesting in relation to the old laws of the French West Indies. In this region there was an exact legal definition of white and coloured. The offspring of a white and an individual with 1 in 256 negro blood was considered white, and could not be held as a slave. So the empiric reasoning of a hundred years ago is substantiated by the scientific investigation of to-day. If negro characteristics unreinforced by new negro blood thus die out in posterity, it is possible that other undesirable characteristics will also become so attenuated as to be at least beyond recognition. As has been frequently pointed out, Nature tends to eradicate the undesirable elements in mankind and to build up gradually a pure stock.

The efforts of the eugenists should be to help Nature and not to take the process out of Nature's wise hands.

Local Government Board Report.

The first part of the annual report of the Local Government Board was issued on Friday last. It contains some matters interesting to the medical reader, including statistics, some crude, some more or less digested. The number of insane persons who on January 1st, 1912, were chargeable to Poor Law unions shows a considerable increase. In every year since 1888 the number has been larger than in the previous year. In 1888 the total was 74,090; in 1912 it was 123,149. As so often pointed out, these figures cannot be taken alone to prove that there has been a real increase in mental diseases; they prove only that a greater number of cases have certified under the Poor Law. The report draws special attention to the problem of the feeble-minded. Many boards of guardians recognise the desirability of removing from the workhouses the feeble-minded, the imbeciles, and the epileptics. Many of them agree that combinations of unions could be formed for providing the necessary accommodation. But they fear the expense; they hesitate to take action; or they think that the matter is one for the county authorities to take up. The Colony, which, as was notified in these columns at the time, was established near Birmingham a few years ago, provides accommodation for 252 patients at an average cost of 12s. a week. This institution has proved an unqualified success, and the committee of management contemplate an early extension of the colony, with provision for children. The circular just issued by Mr. J. Burns reminding boards of guardians of their powers in segregation of all classes of workhouse inmates, ought to stimulate activity in this direction.

Medical Men and the Practice of Cosmetics

A CORRESPONDENT in the *Daily Mail* has recently been much exercised because he happened to consult a dermatologist for the removal of some facial blemish, a procedure which the specialist told him he did not undertake. "Is it possible," he asks, "that the medical profession, which is constantly urging the importance of correct surgical procedure and strictest antiseptic precautions for even the slightest operation, is willing to see its patients pass into the hands of unqualified beauty quacks rather than break through its old-time prejudice against treating anything but an absolute disease?" There is little doubt that the medical profession has, in the past, fought shy of treating minor facial defects through some mistaken idea that such practice would be derogatory to their calling. Most skin specialists nowadays fully recognise that the treatment of naevi, moles, superfluous hair, etc., upon the face comes legitimately within their province. Indeed, there are signs on every hand that the art of cosmetics as a branch of dermatology is gradually being reclaimed from the hands of the unscrupulous and unqualified persons who were formerly its chief exponents. It is not too much to say that operations for electrolysis and the manipulation required for treatment by solid carbon dioxide

demand as much medical training as the performance of an appendicectomy. Medical practitioners should, therefore, think twice before allowing even a minor portion of their practice to be wrested from them and their knowledge exploited by all sorts of false pretenders to medical skill.

The Dublin Congratulatory Addresses.

ONE of the most interesting functions at the Dublin School of Physic Celebrations last July, was the presentation of congratulatory addresses from various universities and other learned bodies. Owing to the number of these addresses and the stress of time, the addresses were merely handed in, and the public had no opportunity either of reading them, or of admiring their artistic embellishments. The Committee of the Celebrations has, however, arranged to give residents in Dublin, at any rate, the chance of examining these documents, and they have been put on show in convenient order in the School of Anatomy in Trinity College. We understand that the exhibition will be open daily until early in October. Most of the addresses are couched in choice Latin, though a few learned bodies have not been ashamed to use the vernacular. The perusal of the documents is as interesting as the study of their decorative features. Several learned bodies pick out for special mention the names of various of Dublin's great men. Those who stand out pre-eminently are naturally Graves and Stokes, but many others, from Stearne, Dunn, and Cleghorn, down to George Fitzgerald and Daniel Cunningham, receive honourable remembrance.

Swansea Hospital Staff and the Insurance Act.

At a meeting of the Swansea Hospital Committee last week a strong position was taken up by the consulting and acting medical staff with regard to the Insurance Act. It was stated that they had, with one exception, pledged themselves not to attend insured persons through the service of any voluntary medical charity except in cases of urgent necessity, after the medical benefit under the Act became due and until the profession had approved of the terms which should govern its administration. It was urged on behalf of the staff that the scandal which they wanted to stop, and which for years they had been unable to stop, was the continuance of underpaid contract work. The very class which they were told would be affected if the action of the medical staff were carried into effect were those who for years had been victims of a system which they regarded as deplorable. The medical staff declare that they have seen the results of the underpaid contract work outside the hospital, and feel that though their action may inflict a certain amount of inconvenience, it is nothing compared with the evil which they are trying to bring to an end, and which the Government is seeking now to perpetuate and extend. The staff insist that no work is so bad as sweated work; the terms given throughout the kingdom by friendly societies. Further consideration of the question has been put off until the end of November.

The *Ætiology* of Pellagra.

SINCE the day when it was believed that the observations and experiments of Lombroso had demonstrated the causation of pellagra to be due to the consumption of unsound maize, further attempts to arrive at the truth in this research have been periodically chronicled in these pages. In 1911 Dr. Sambon and Dr. A. J. Chalmers discovered a new protozoal organism in the brain and spinal cord of a pellagra case, and they also found other minute organisms, possibly related to this parasite, in the blood and cerebro-spinal fluid, and in the liquid from skin lesions in victims of the disease. Through the munificence of Mr. Henry S. Wellcome, who has borne the expenses of all subsequent work, Dr. Sambon and Dr. Chalmers have been enabled to continue their research in Egypt, in Italy, and especially in the islands of the Venetian lagoon. The exact systematic position of the new protozoon and its relation to pellagra are matters which still require further investigation; but a great step has been taken towards the elucidation of the true cause of the disease. It has been proved that the island fishermen contract the disease whilst fishing along the mainland coast, where it is everywhere prevalent. The fishermen gave evidence that from March to May, whilst fishing near the outflows of rivers and streams, they are attacked by minute flies called "mosciolini." This fact has been verified, and the flies in question, *Simuliidæ*, are proved to be abundant in all local rivers and many streams. The immunity of the great bulk of the inhabitants who remain on the islands affords corroborative evidence of the insect-borne origin of the malady, and if this is not yet scientifically demonstrated there is left very little doubt about it. In view of the triumph of practical science in the similar instance of the Panama Canal zone, the extinction of pellagra seems now merely a question of money, of energy and of time. The disease is most prevalent in Italy. The Italian Government has been for many years devoting more and more attention to questions of public health; it will, if called upon, surely provide the further funds needed to carry on to the end a work of such vital importance to its people.

PERSONAL.

THE prizes at the Middlesex Hospital will be distributed by Sir Charles Wyndham, M.R.C.S.

DR. W. S. LAZARUS-BARLOW will speak on the "Genius of the Infinitely Little," and at the subsequent dinner Dr. H. Campbell Thomson will occupy the chair.

PROFESSOR NORMAN DALTON will preside at the inaugural dinner of King's College Hospital at the Waldorf.

AT St. Mary's the Lord Mayor will deliver a short address, and in the evening Dr. W. J. Gow will preside at a dinner at the Prince's Restaurant.

AN introductory address on "Common Sense" will be delivered by Miss Jane Walker, M.D., at the London School of Medicine for Women.

THE LORD MAYOR, Sir Thomas Crosby, is to take the chair at a dinner of old students of St. Thomas's Hospital, to be held at the Hotel Cecil.

IN the Great Hall of St. Bartholomew's Hospital a similar dinner is to be held for old students, when the chairman will be Dr. Lewis Jones.

ON Prof. Sir Almroth Wright has been conferred the title of Professor in Experimental Pathology in the University of London.

SIR BERKELEY MOYNIHAN, F.R.C.S., of Leeds, opened a tuberculosis exhibition in the Town Hall, Huddersfield, last week.

LIEUT.-COL. A. E. TATE, R.A.M.C., has been selected for appointment as Honorary Physician to H.E. the Viceroy and Governor-General of the East Indies.

CAPT. A. B. SMALLMAN, R.A.M.C., has been selected for appointment as Clinical Pathologist to the Queen Alexandra Military Hospital, London, on the departure of Major J. C. B. Statham.

DR. GEORGE SENTER, Lecturer on Chemistry at St. Mary's Medical School, has the distinction of being the only lecturer on that subject appointed Reader of Chemistry in the University of London.

AT a recent dinner in honour of the occasion, a handsome silver loving-cup was presented to Dr. Handfield-Jones by the staff of St. Mary's Hospital, to which he has been attached since the year 1874.

AT the London Hospital, the Schorstein Memorial Lecture will be delivered by Professor T. Wardrop Griffith. In the evening a dinner will be held at the Savoy Hotel, Mr. Jonathan Hutchinson in the chair.

AT St. George's the inaugural address on "The Present Duty of the Medical Citizen" will be delivered by Mr. H. B. Grimsdale. In the evening there will be a dinner at the Prince's Restaurant, at which Dr. F. C. Penrose will preside.

COL. SIR GEORGE T. BEATSON, K.C.B., M.D., on vacating the appointment of Assistant Director of Medical Services of a Territorial Division, and resigning his commission, is granted permission to retain his rank and to wear the prescribed uniform (dated September 11th, 1912).

ON October 2nd the session is to open at the Charing Cross Hospital with a distribution of prizes by the Bishop of Peterborough and Lady Mary Glyn, and to celebrate the opening at University College Hospital, a dinner is to be held later at the Café Royal, when Sir Rickman J. Godlee, President of the Royal College of Surgeons, will preside.

H.M. THE KING has given Mr. Robert John Gordon, M.A., M.B., B.Ch., B.A.O., R.U.I., of the Irish Presbyterian Mission, his authority to wear the insignia of the third class of the Third Grade of the Order of the Double Dragon, conferred upon him by the Emperor of China in recognition of valuable services rendered by him as Plague Prevention Medical Officer at Hulan, Heilungchiang.

H.M. THE QUEEN visited the Royal Hospital for Sick Children, Aberdeen, last week. Sir Alexander Ogston, Honorary Surgeon to the King, and the members of the medical staff of the hospital, had the honour of being presented to Her Majesty.

LORD STRATHCONA will lay the foundation-stone of the Queen Alexandra wing, which is being erected as part of the scheme to celebrate the jubilee of the British Home and Hospital for Incurables, Streatham, on Saturday, October 19th.

SIR WM. TURNER, K.C.B., F.R.C.S., Principal of Edinburgh University, has been honoured by the Emperor of Germany with the insignia of the Royal Prussian Order of Merit, in the department of science.

FRENCH CLINICAL LECTURE

ON

AN INFECTIOUS DISEASE CHARACTERISED BY JAUNDICE AND A MENINGEAL SYNDROME.

By Dr. GEORGES GUILLAIN,

Professeur Agrégé à la Faculté de Médecine de Paris.

[SPECIALLY CONTRIBUTED TO THIS JOURNAL.]

In conjunction with M. Charles Richet (*fils*) I called attention, in 1910 (*a*), to an affection specially characterised by jaundice and a meningeal syndrome, which had not hitherto found a place in our accepted nosology. At that time we searched carefully through the medical literature both of France and of other countries for recorded associations of meningeal and icteric syndrome, but failed to find such co-existence. Accordingly, we were much struck by observing four cases of such coincidence in the summer of 1910; all of which had evolved in almost identical fashion, and all had recovered. Thus it seemed to us interesting to group together those observations of a clinical entity not previously described (*b*).

To our own four cases we have added one observed by MM. Laubry and Foy (*c*), and another by MM. Laubry and Parou (*d*). The former case was that of a man, *æ*t. 27, who presented a meningeal syndrome with cerebro-spinal polynucleosis, accompanied by gastro-intestinal troubles and sub-icterus; the latter was a youth of 17 who also showed a meningeal syndrome with cerebro-spinal lymphocytosis, and accompanied by sub-icterus. It must be noted that neither of these two cases caused loss of colour of the *fæces*, which was present in the cases which I had observed with M. Charles Richet (*fils*).

At the same meeting of the *Société Médicale des hôpitaux de Paris*, at which we reported these cases, an epidemic of meningeal derangements, accompanied by clear and non-microbic cerebro-spinal fluid was reported by MM. F. Widal, A. Lemierre, Cotoni, and Kindberg (*e*). The memoir prepared by these authors contains two observations closely analogous to ours. One of them was the case of a man, *æ*t. 30, who presented an infected condition accompanied by a meningeal syndrome and icterus; the latter was fairly well pronounced, and accompanied by choluria and loss of colour of the *fæces*, and it had appeared at the moment of the fall of temperature and the cessation of meningeal symptoms. The second of their cases was that of a youth of 17 who presented a corresponding condition; but the sub-icterus of this patient was accompanied by the presence of abnormal pigments in the urine, and lasted but two days (the most acute period of the symptoms). Each of those cases recovered in a few days.

MM. Noël Fiessinger and Sourdel reported to the same society, in March, 1912, a meningeal case accompanied by infective icterus, and on that occasion M. de Massary briefly related the features of an analogous case. Accordingly, there now exists a serial record of cases of the clinical type which formed the subject of our observation in 1910.

The affection described by us has, in all the cases hitherto published, presented a symptomatology almost identical. The onset is usually sudden, and

is characterised by headache more or less severe; with pain in the back, prostration, vomiting, and elevation of temperature. When developed, there are two groups of symptoms: meningeal and hepatic. Others are added as the case progresses: Digestive, urinary, and cardiac. The meningeal syndrome is distinguished by headache, which is often extremely violent, rigidity of the neck, nystagmus, and vasomotor lines. Diminution or abolition of patellar reflex developed, but we have never noticed paralysis. In one of the observations published by MM. Widal, Lemierre, Cotoni, and Kindberg, it was noticed that the reflexes of the upper limbs were feeble; in another they were diminished; in the case of MM. Fiessinger and Sourdel they were unaffected; in that of a patient of MM. Laubry and Parou, the patellar reflexes were exaggerated. Lumbar puncture allows the determination of the hypertension of the cerebro-spinal fluid, which remains limpid—sometimes with an increase of albumen, but always with a very distinct cellular reaction, polynuclear or lymphocytary; the polynuclear cells, more or less altered, disappear rapidly; and are replaced by the lymphocytes. The meningeal reaction may persist for many weeks. We have not been able to detect microbes in the cerebro-spinal fluid of any of our patients, either by direct staining, or by *æ*robic and *anæ*robic cultures. The fluid has remained inactive, too, when inoculated in the mouse, rabbit, and guinea-pig; and even when injected beneath the *dura mater* of a monkey (*Macacus Cynomologus*). The other observers also failed to find any microbic agent in the cerebro-spinal fluid, except that MM. Noël Fiessinger and Sourdel obtained, by cultures of the blood and cerebro-spinal fluid, a slender bacillus of slight motility which did not take the Gram stain; this bacillus could not be grown on any media, *æ*robic or *anæ*robic, so that its vitality must have been very feeble. Accordingly, these observers wisely refrained from making any conclusion regarding its pathogenic action.

The icterus usually presents the character of a benign infective type. In our first patients it was fairly intense, with loss of colour of the *fæces*, cholæmia and choluria; it lasted for a good number of days, and disappeared rapidly. It was, doubtless, hæmatogenous; it was not hæmolytic, but rather an icterus by retention—or, indeed, *with retention*. In the case of the patients of MM. Laubry and Foy and of MM. Laubry and Parou, was not accompanied by loss of colour of the *fæces*. We have already noted that in the case of one of the patients of MM. Widal, Lemierre, Cotoni, and Kindberg there was choluria and loss of colour of the *fæces*; and that in their second patient there was merely a sub-icterus, with abnormal pigments in the urine, which only lasted for 48 hours, and during the most acute stage of the symptoms. In the case observed by MM. Fiessinger and Sourdel, the icterus had graver complications; there was purpura, with diminished coagulability of the blood and non-

(d) *Ibid.*, October 21st, 1910.

(e) *Ibid.*, October 25th, 1910.

contractility of the clot; there was also, besides the grave icterus, a very active infective hepatitis; nevertheless, the patient recovered rapidly, as in the cases in which the icterus presented symptoms much less serious. In the observation recorded by M. de Massary, the icterus, in contrast to that of the other cases, was the first sign to appear; it was when convalescence was expected that the meningeal phenomena presented themselves.

There are other indications, besides the meningeal and hepatic ones, which go to show the infective nature of this clinical entity. Fever is always present, and the thermic curves are all of the same type: a rapid ascent to 102° or 104°, followed by a gradual defervescence, reaching the normal in six to eight days. Herpes has often been observed. Examination of the blood has generally shown a slight leucocytosis (polynuclear neutrophiles; 80-90 per cent. polynuclear). Granular *hematies* are absent, the globular resistance is normal, and neither auto-hemolysin nor hetero-hemolysin is present. Albuminuria was noticed in each of our patients, constant but transitory; a slight disc of albumen was found in the cases recorded by MM. Fiessinger and Sourdél. In one of our patients the cardiac complication looked serious at first; the patient was extremely asthenic, and with a tendency to syncope; there was a condition of embryocardia, with extremely pronounced tachycardia and very low arterial pressure. MM. Fiessinger and Sourdél also noted in their patients: "Heart sounds dull and feeble, with a tendency to embryocardia (115-120 beats per minute). Arterial hypotension appears to be frequent; the asthenia possibly depends on suprarenal trouble. At first, the general condition may seem grave (typhoid aspect, high temperature, hyperpyrexia, meningeal symptoms), but amelioration is soon observed, and the febrile period lasts but from six to eleven days." All our own patients have recovered without visceral complications or any nervous sequelæ, and so also those of the physicians above referred to. In three cases there was a slight relapse at the end of a few days.

The prognosis appears to be favourable, although it is, perhaps, desirable not to express too great confidence. In one of our cases, the cardiac symptoms of bulbar or myocardial origin were really alarming, and might have been fatal; and the hepatic symptoms were grave in the case observed by MM. Fiessinger and Sourdél.

The diagnosis of *Icterus with a Meningeal Syndrome* is easy when we have come to recognise its existence as a clinical entity. Accordingly, we found the diagnosis difficult in our first two cases, but the previous experience made it easy in the later ones. Two of our patients had been sent to hospital with a diagnosis of *cerebro-spinal meningitis*. The onset is, indeed, suggestive of cerebro-spinal meningitis, and we usually thought of this disease first. The results of lumbar puncture establish the absence of the meningo-coccus. The cerebro-spinal fluid remains limpid, and this is comparatively rare in cerebro-spinal meningitis. The meningo-coccus is also easily discoverable in the naso-pharynx in cases of the latter.

It is distinguished from *tubercular meningitis* by the clinical course, the rapid tendency to recovery, and the absence of Koch's bacillus. The clinical course easily distinguishes it from *syphilitic meningitis*. Wassermann's reaction should always be tried, but it must always be remembered that a syphilitic patient may derive the reaction from a source other than meningeal. There are meningeal cases unaccompanied by icterus, to which M. Widal has drawn attention, which are distinguished by the absence of the hepatic syndrome; and the menin-

geal reaction observed by MM. Widal and Abrami in a fatal case of infective icterus, with uræmia and urea in the blood, differs in every respect from those we are now studying. Of course, the headache, fever, asthenia and digestive disorder which accompany the onset may suggest *influenza*, *typhoid fever*, a *paratyphoid infection*, or *alimentary intoxication*. In one of the cases above referred to, the medical attendant at first suspected poisoning by tunny fish; and another physician sent the patient to hospital, some days afterwards, with a diagnosis of mucous fever. When the diagnosis is doubtful, recourse should be had to the various laboratory procedures: blood cultures, sero-diagnosis, and hæmatological examination. In some cases the possibility of mushroom poisoning may be suspected. But when the period of coincidence of the icterus and the meningeal syndrome is reached, the diagnosis may be made with certainty.

With regard to ætiology and nosographic position, we must indicate that all the patients were young (18 to 25 years), and were of the male sex. Then, as we pointed out in 1910, we are not dealing with cases of cerebro-spinal meningitis. The presence of the coccus was never revealed by direct examination of the centrifuged clot of the cerebro-spinal fluid; nor by cultures, or by inoculation. Other observers have had similar experience. Besides, icterus is very rare in cerebro-spinal meningitis; MM. Netter and R. Debre have recently informed us (*La Méningite Cérébro-spinale, Paris, 1911*), that Dr. Besseron (of Algiers) formerly observed this syndrome; but attributed it, not to a cerebro-spinal meningitis, but to the effects of an extremely bilious constitutional condition which then prevailed at Algiers. Icterus has since been observed in cerebro-spinal meningitis. Cassel has reported three cases. We have ourselves observed one.

M. Netter, after the communication of MM. Widal, Lemierre, Cotoni, and Kindberg, and our own, pointed out that the benign meningitis of 1910 sometimes presented a recrudescence corresponding to that of poliomyelitis. I do not, however, believe that the *icterus with a meningeal syndrome* falls under the heading of the disease of Heine-Medin. None of our patients showed paralysis, either medullary or bulbo-ponto-peduncular. Poliomyelitis may, indeed, accompany any visceral disorder; but, so far as we know, the association of icterus with symptoms indicative of lesion of the neural axis has not been recorded in epidemics of poliomyelitis. With regard to the epidemic of meningeal conditions associated with clear cerebro-spinal fluid free from microbes, we have the testimony of MM. Widal, Lemierre, Cotoni, and Kindberg: "Epidemic poliomyelitis seems to us to be without assignable cause. None of our patients have shown any trace of paralysis; besides, we have never observed at Cochén any except isolated and very rare cases of poliomyelitis, the latest dating from four years." The patient recently observed by M. de Massary belonged to a part of Paris where no epidemic of either cerebro-spinal meningitis or poliomyelitis existed, and M. de Massary adds: "The question of epidemicity, which was raised by M. Netter after the communication made by MM. Guillaïn and Charles Richet (*files*) in October, 1910, should not, then, be raised in connection with this last case."

Icterus with a meningeal syndrome appears to be contagious. One of the patients whom I observed with M. Charles Richet (*files*) worked in the same room with another artisan who was similarly affected; whose case was reported by MM. Widal, Lemierre, Cotoni, and Kindberg. We found on inquiry that this patient had replaced the other, and had actually used his tools. These cases

have, perhaps, some relation to those of benign meningitis referred to by the various authors mentioned, and also by MM. Rist and Rolland. In discussing our communication, M. Rist observed that he had been greatly struck in the summer of 1910 by noticing, at the same time as the occurrence of a number of cases of benign acute meningitis, an unusual number of benign cases of infective icterus by retention. "I had not dreamed," said he, "of establishing a connective bond between these cases of icterus and those of meningitis of which I spoke the other day, but the observations of M. Guillain are very suggestive in this regard."

In summarising, I would say that there seems to exist among the benign forms of meningitis, the meningeal conditions to which M. Widal has called attention, a special clinical type which deserves to be individualised; this is characterised by the association of a meningeal syndrome and an icteric syndrome. The infection which produces the *icterus with meningeal syndrome* would seem to be a septicæmia. This septicæmia may affect the heart, the lungs, or the suprarenal capsules, but it specially determines hepatic and meningeal troubles—troubles apparently serious, but which, in every case hitherto recognised, have terminated in recovery.

Not knowing the microbic agent which determines the genesis of this disease, we are unable to oppose it with a pathogenic therapeutics. But, apparently, this *icterus with a meningeal syndrome* may be cured without medicaments. Lumbar puncture is useful for diminishing the hypertension of the cerebro-spinal fluid, for removing a fluid which is surely injurious to the neural axis, and for modifying the meningeal circulation.

Urotropin, benzoate and salicylate of sodium, aspirin, salts of quinine are medicaments which have an influence on general infection, and especially in case of hepatic localisation. Cold lavements are of real benefit during the icteric phase. Adrenalin does great service when the blood-pressure is low, and suprarenal trouble appears to exist. In the grave infective conditions, I would advise the use of collargol and electrargol. It is, however, useless to give a patient too many drugs, for "*icterus with a meningeal syndrome*" habitually tends to a spontaneous cure.

NOTE.—A *Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by H. L. McKisack, M.D., M.R.C.P., Physician to the Royal Victoria Hospital, Belfast. Subject: "Syphilis of the Nervous System; Illustrated by Three Cases."*

ORIGINAL PAPERS.

ON A CASE OF MIGRATION OF THE CÆCUM PRODUCING OBSTRUCTION OF THE ASCENDING COLON.

By SIR JOHN BLAND-SUTTON, F.R.C.S., ENG.,
Surgeon to the Middlesex Hospital.
FROM NOTES BY SOMERVILLE HASTINGS,
F.R.C.S., ENG.,

Formerly Surgical Registrar to the Middlesex Hospital.

I was interested in Mr. Gordon Taylor's admirable article on "Volvulus of the Small Intestine" in the Archives of the Middlesex Hospital (Clinical Series, No. X., p. 45), because one of these dangerous cases of volvulus in which the small intestine, cæcum, and ascending colon are slung on a common mesentery came under my observation in the hospital in 1908. I was puzzled by it, and published a description of the case in the *Lancet*

(1908, vol. i., p. 1837). By a singular mischance when the index was prepared the reference to it was omitted. On these grounds I venture to reprint it.

The following is the reprint of my article:—

"When the cæcum is provided with a long meso-cæcum it may lie in any region of the abdomen; perhaps the most unusual situation for a displaced cæcum to occupy is the left kidney pouch, behind the mesentery. When a cæcum migrates in this way it gives rise to a puzzling set of symptoms, as the following case will serve to illustrate:—

"A poorly nourished man, 48 years of age, came under my care in the Middlesex Hospital for abdominal pain and vomiting. A week before admission he had been seized suddenly with griping pains in the abdomen, particularly on the right side; these were sufficiently severe to confine him to bed, and were followed by anorexia and vomiting. The vomit was bile-stained and watery. On admission the abdomen was somewhat distended, but moved evenly on respiration; no tumour could be felt, and there was not much tenderness. The temperature ranged about 100° F. As these signs indicated the existence of intestinal obstruction, celiotomy was performed. On making a free median incision several ounces of purulent fluid escaped and the intestines appeared inflamed and moderately distended. Attention was first directed to the right iliac fossa, but the cæcum and appendix were not there. A tense band of gut extended from the right extremity of the mesentery upwards and to the left, overlapped by mesentery and coils of small intestine; when traced upwards it led to the ileo-cæcal junction in the left kidney pouch. A loop, consisting of the last few inches of the ileum and the ascending colon with the cæcum and appendix, had been twisted on its own axis through half a circle and displaced upwards and to the left. The cæcum had become adherent in its new situation, and when drawn down a large necrotic area with two perforations was seen, through which liquid fæces issued. The necrotic area was excised, and the edges of the hole thus made in the gut were approximated with sutures. The free fluid in the abdomen was swabbed out, a large rubber tube was introduced into the pelvis, and the incision was closed with silk sutures. The man died 16 hours after the operation.

[The relations of the parts were identical with those represented in Fig. 4, p. 55, of Mr. Gordon Taylor's article.]

"The patient whose clinical history and fate I have described came under my observation in October, 1906. I was interested and much puzzled by the condition found at the operation; my interest was increased by reading a valuable contribution by Mr. Jonathan Hutchinson, jun., on 'Volvulus of the Entire Small Intestine and Ascending Colon.' This communication was founded on a case which is in its leading features like the one which I have endeavoured to describe, but Mr. Hutchinson fortunately saved his patient; he also made his paper valuable by furnishing an analysis of nine other similar cases of volvulus. Mr. Harold W. Wilson has since published an account of a case of migration of the cæcum producing obstruction of the ascending colon which occurred in St. Bartholomew's Hospital in the practice of Mr. Harrison Cripps, which resembles my case in its main features.

"This complication connected with the cæcum is worth the attention of surgeons, as descriptions of it are not to be found even in monographs dealing with intestinal obstruction. Its importance is obvious from the fact that the majority of the patients in whom it has occurred have died. Judging from a study of the recorded cases it would

appear that the chief variations in the degree of the displacement depend upon the extent to which the twist or rotation involves the mesentery. For example, the extreme condition occurs in patients in whom the intestines, including the third part of the duodenum, the cæcum, and ascending colon, are attached to a common mesentery. When such an anatomical condition exists, and it is a recognised anomaly, the whole of the small intestines, the cæcum, and ascending colon may be concerned in the volvulus. In my patient the parts implicated included the terminal 12 inches of the ileum, the cæcum with the vermiform appendix, and half the ascending colon. The condition of the third portion of the duodenum was not noted either at the operation or post-mortem. During the operation the absence of the cæcum from the right iliac fossa was detected as soon as the abdomen was opened, because it is with me a matter of routine in operations for intestinal obstruction to ascertain the condition of the cæcum as the primary step after exposing the abdominal viscera.

"I think the fatal nature of this form of volvulus is mainly due to delay on the part of hospital patients in seeking advice. The signs are not so urgent as in acute obstruction of the small intestine, and when the patients are admitted the obstruction may not be absolute, for enemata bring away small quantities of flatus. Abdominal distension is not a marked feature. In the case under my own care the diagnosis seemed to lie for the first few hours between perforation of the appendix and intestinal obstruction; then the indications of obstruction prevailed. The signs of perforation were not counterfeited, for, as has already been mentioned, there were two holes in the wall of the cæcum. The man was gravely ill at the very hour of his admission."

Since studying this case I have examined the disposition of the cæcum carefully when performing pelvic operations, and have found that the predisposing condition, which allows the cæcum to pass behind the mesentery and lodge in the left kidney pouch, is by no means uncommon, and I have often demonstrated it in the operating theatre to those assisting at or witnessing operations.

Mr. Gordon Taylor made his article more useful by collecting reports of cases in which patients had recovered after the removal of more than six feet of small intestine. I add two to his series.

In 1905 I was asked one midnight to see a woman who had been curetted eight hours previously with the hope of relieving painful menstruation. In the course of the operation the uterus was perforated by a dilator, and a coil of ileum protruded through the hole. The medical attendant thought this was a product of conception and withdrew more than six feet of intestine. He cut off one end and forcibly pulled out the other, and returned the patient to bed, thinking she would quickly die. At midnight he recovered his presence of mind and asked me to help him. I opened the abdomen, swabbed out the effused blood, closed the rent in the uterus, resected that portion of the mesentery which had been deprived of intestine, and joined the cut end of the ileum into the cæcum at the ileo-cæcal valve, for the ileum had been torn out of the cæcum. The patient recovered. I saw her six years afterwards in excellent health and quite ignorant of the nature of the serious ordeal through which she had passed.

These facts prove, if any facts were needed, that the loss of a long segment of ileum does not seriously impair the health of the individual.

Some years ago Mr. F. J. Shepherd, Professor of Surgery, McGill College, Montreal, showed me a large globular tumour weighing eight pounds which he had removed from the mesentery of a

Newfoundland fisherman, æt. 28. The extirpation of the tumour involved the resection of nearly eight feet of small intestine. Three years later, and one week previous to my visit to Montreal, the patient had reported himself at the hospital in robust health.

AN INQUIRY INTO THE CAUSES OF FAILURE OF X-RAY TREATMENT IN DEEP-SEATED CANCER. (a)

By FRANCIS HERNAMAN-JOHNSON,
M.D. ABERD.,
Darlington.

MUCH may be learned in an inquiry of this nature by a study of rodent ulcer. It is easy to cause the disappearance of a rodent; difficult to prevent relapse. Relapse is commonly believed to be due to the fact that some of the deeper malignant cells have not been killed; until we can learn how to destroy such cells at a depth of a few millimetres, it is useless to look for success in visceral cancer.

In the first place, why do X-rays cause a rodent to heal even temporarily? The usual theory is this: X-rays are, to a certain extent, injurious to all cells. Malignant cells are of lower vitality than normal cells; hence, a dose from which normal cells will recover will prove fatal to cancer cells. The action is thus held to be similar to that of carbon-dioxide snow; or, as Dr. Bashford put it in an article now famous through the daily press, X-rays and radium are the best caustics known, but still, simply caustics. Such a view is worthy of the days when all the phenomena of absorption and secretion were held to be explicable by the ordinary laws of diffusion and osmosis. No known caustic can produce at one and the same time stimulation and depression; yet this is accomplished by X-rays. In the case of a chronic varicose ulcer, we see an action wholly stimulating. A surface epithelioma not yet ulcerated shows under rays a gradual absorption, chiefly due to depression and death of malignant cells. A healing rodent displays to us both these processes simultaneously—destruction of cancer cells proceeding coincidentally with increased activity of normal epithelial and connective tissue elements.

If we accept the biological view of the cancer cell, regarding it as a reversion to an earlier type, its behaviour under Röntgen irradiation is seen to be only what might be expected from what we know of the effects of radio-activity on cell-life in general. Röntgen rays, even in minute doses, are injurious to young cells, or to cells retaining the peculiarities of extreme youth. Now the cancer cell is a cell which has resumed certain embryonic characteristics. It has become simple in structure and function, tends to divide and subdivide with great rapidity, and, like the fertilised ovum from which it sprang, seeks to live upon its immediate surroundings. According to the views of Mr. Hastings Gilford, as set forth in a recent work, (1) such cells are the subjects of a regressive variation. They are prematurely senile, and therefore present a kind of anarchic caricature of their infancy. Why X-rays should be destructive to embryonic cells it is not my purpose to discuss; but it is because the cancer cell is of this type that the X-ray seeks it out amid its normal brethren—seeks it as definitely as quinine does the parasite of malaria, or mercury the spirochæte of syphilis. Quinine, if too much is given, will kill the patient, as also will mercury; yet we do not therefore deny the selective action of these remedies on the causative organism of malaria and

(a) Read before the Section of Electro-Therapeutics, British Medical Association Annual Meeting, Liverpool, 1912.

syphilis. Absolute selection does not exist in medicine; but the action of X-rays on embryonic cells is truly selective as any known to therapeutics.

I have dwelt on this theory of reversion to embryonic type because it seems to me that it furnishes us with a clue to the therapeutic action of X-rays in cancer, rheumatoid arthritis, spinal cord degenerations, leucæmia, and other maladies classed by Gilford among "Disorders of Post-natal Growth and Development." Not only has it enabled me to fortify an instinctive belief in the selective action of X-rays by sound biological arguments, but it has also allowed me to banish from my mind the fear of actually stimulating deep-lying malignant cells by insufficient dosage. This has been suggested as a possible cause of failure by well-known authorities, notably Professor Rowntree. (2) That moderate doses of X-rays have a stimulating effect on normal tissues is, fortunately, beyond doubt; but it does not follow that even very small doses will have a similar effect on malignant cells. Approaching the matter from a clinical side, I have endeavoured to determine the smallest dose of rays which would benefit a rodent ulcer; and I have seen distinct improvement from the employment of only one-fifth of a milliampère of secondary current for seven minutes twice weekly, the anticathode being 25 c.m. from the skin. Biological experiment also tends to discredit the deep-stimulation theory as an explanation of therapeutic failure. Dr. J. F. Gaskell, in the course of a paper read last year before the Royal Society, (3) states that even very small doses of X-rays have a retarding effect on the cell mitosis of developing chicks. It is true that a chronic Röntgen dermatitis may become malignant, but in this case the skin is first broken; the influences at work are not limited to X-rays, and bacterial toxins may in reality be the exciting cause. On the whole, it appears fairly evident that the Röntgen dosage received by the deeper parts of a tumour, though it may not be enough altogether to inhibit the growth of cancer cells, certainly does not increase their vitality.

In every case of rodent ulcer which heals satisfactorily on the surface, it is probable that the superficial cancerous tissue has been killed, and sufficient rays have reached the deeper malignant cells to hold their proliferating activity in check during the actual course of treatment. But in many instances the dosage received is insufficient actually to kill these cells, and relapse inevitably follows. That the mitosis of embryonic cells can be inhibited for long periods without permanently damaging them is a matter beyond doubt. Dr. Gaskell, in the paper above referred to, tells us that for each day of development there is a certain "critical dose" which kills the embryo; whereas from anything less than this it will, in time, recover. This critical dose varies with what is known as the *Mitotic index*, this being the number of divisions per 1,000 cells occurring in a given time. As the index diminishes, so does the critical dose. Instances are on record of radiologists who have been sterile for months or years, (4) but who have quickly recovered so soon as they took proper measures of protection. Moreover, even with deliberate intention, it is often difficult or impossible permanently to sterilise women not near the menopause.

If I am right in believing that X-rays depress cancer cells because they have become embryonic in type, then the above quoted experiments and observations may help to explain the cause of failure or relapse in some cases of cancer. We shall not, I think, exceed the bonds of legitimate hypothesis if we assume that for the cells of any given tumour there exists a critical dosage of X-rays from which

they are unable to recover. This dosage will vary according to the mitotic index of the growth concerned. The mitotic index, again, will differ in various tumours, even such as closely resemble each other from a clinical standpoint, and will not remain a constant even for the same tumour. I use the term "critical dosage" rather than "critical dose," because the amount need not necessarily be all delivered at one sitting; whichever term is used, the idea to be conveyed is one of definite quantity within a definite time. Thus, the determination of the number, strength, and frequency of irradiations is seen to be a matter of the utmost importance. *For a dosage below that which is critical for the cells of a given tumour will never kill these cells, no matter if it be administered for months, or even years.*

To treat a rodent ulcer with unfiltered rays from a medium tube is to invite failure. For the surface receives a bombardment wholly disproportionate to that sustained by the deeper layers. Not only are numerous soft rays emitted from the anticathode, but a vast number of *adventitious primaries* are given off as a result of electrons striking on the glass of the bulb. All these are highly active physiologically within narrow limits, and, as a consequence, the ulcer heals rapidly on the surface. Cessation of treatment will almost certainly be followed by relapse; while persistence will result in surface irritation.

No case of rodent ulcer should relapse because the deeper layers have received a relatively feeble dose of rays. Bulbs can be obtained whose radiation, after being filtered through 2 mms. of aluminium, will penetrate at least 3 to 4 cms. of tissue before falling half value, and they can be excited by any good modern coil worked from the main. The fall in value at a depth of 1 cm. is so trifling that it may be disregarded. For the past year I have employed in the treatment of rodent ulcer hard filtered rays intensified by the specific secondary radiation from silver or zinc, and am well pleased with the results so far; but it is as yet much too early to form any conclusion as to whether this modified *technique* materially reduces the tendency to relapse. In the meantime, I am not unmindful of the possibility that, even though we convey a critical dose of rays to every cancer cell in a given tumour, we may not thereby cure the disease. For it is conceivable that, at any rate in a proportion of cases, some irritant remains which continually provokes fresh normal cells to premature senile degeneration.

To attack the problem of the treatment of deep-seated cancer by observations on rodent ulcer is open to anyone possessing an X-Ray apparatus. Another method, recently made possible by the success of Carrel and Burrows in the growing of human tissues *in vitro*, requires the collaboration of a skilled pathologist. By the irradiation of living neoplasms under experimental conditions outside the body, we should be able to ascertain:—

(1) The minimum dosage required permanently to stop growth.

(2) Whether recovery is complete from any dosage less than this.

(3) Whether the minimum dosage varies according to the rate of growth.

Put in other words, does there exist for all malignant tumours a "Critical Dosage," and, if so, is it determined in every case by the "mitotic index" of the tumour concerned.

By the coincident exposure to X-Rays of normal tissues and their malignant derivatives it may be possible to obtain direct experimental proof of specific vulnerability in cancer cells. From this it is but a step to the determination of the maximum depth at which an efficient dose can be delivered

without permanent injury to superjacent healthy structures.

Meanwhile, we, as physicians practising a speciality, are called on to do our best for inoperable, or recurrent, cases of internal cancer. Knowing what we do of the relative susceptibility of the cancer cell to X-Rays, we may assume that a dose equal to half, or even one-quarter, the maximum which can be tolerated by the integument is still effective as a depressant to such cells. Existing methods enable us to give this amount at a depth of between 3 or 4 cms., even when only one skin path is available. But we may often reach a deep-seated lesion by two or more such paths. It is my own practice to irradiate with two tubes connected in parallel, and so placed that their normal rays either meet at right angles or are in opposition. A "cross-fire" effect is thus obtained. The anticathode should be not less than 35 or 40 cms. from the surface of the body, so that for practical purposes we may disregard loss of energy owing to divergence of the incident rays after they enter the tissues.

In treating rodent ulcers we can look out for and deal with small relapses, and there is little likelihood of dissemination. But in cancers of the viscera we cannot see what is going on, and it is, therefore, necessary always to give the largest amount of X-Rays which the skin will stand. *The risk of metastasis can be forestalled only by a careful study of the sites peculiar to each form of cancer, and by their prophylactic irradiation.*

When very stout subjects are concerned, the hardest existing bulb is not always capable of delivering an effective dose to an internal tumour without grave injury to the skin. We must, therefore, demand from the makers an increase in the penetrative power of their tubes. We should aim at a penetration at least double the maximum now attainable.

Rays of such extreme hardness can be utilised to the best advantage only by converting their energy at the site of the lesion. Secondary ray therapy, at present only in its infancy, may eventually enable us to do this effectively. At present we are quite unable to irradiate, say, a gastric carcinoma as freely as a rodent ulcer; until we can do so with safety to the intervening structures X-Rays, *per se*, cannot be said to have been given a fair chance in deep-seated cancer.

THE VACUUM ELECTRODE IN NEVRODERMITE. (a)

By J. GOODWIN TOMKINSON, M.D.,

Physician for Skin Diseases to the Out-Patient Department, Glasgow Western Infirmary; Medical Electrician (Dermatological) Glasgow Western Infirmary; Consulting Dermatologist, County Council of Lanark, &c., &c.

In recent years the curative and palliative value of X-rays and of radium in certain itching affections has been recognised, but the application of these potent physical agents is not invariably successful. The value of high frequency currents in pruritic conditions has not, in my opinion, received that general recognition which it deserves. My attention was directed some years ago to their use by Lacapère in the out-patient department of L'Hôpital Saint Louis.

(a) Abstract of paper read before the Dermatological Section of the British Medical Association, July, 1912.

The first case in which I employed the vacuum electrode for the relief of localised intense itching was one of pruritis ani. The patient was a man in the early prime of life. The condition had become chronic, and was markedly rebellious to ordinary therapeutic measures. I think I am justified in regarding the condition as permanently cured, for after a slight relapse, nine months after the first course of treatment, I have not been again consulted by the patient.

Professor Gaucher, in volume XIV. of the "Nouveau Traité de Médecine et de Thérapeutique" (Brouardel et Troinot), says: "L'application des courants de haute fréquence est aussi un excellent mode de traitement du lichen simplex chronique, comme d'ailleurs de tous les épaissements lichénoïdes de la peau."

In the affection variously described as lichen simplex chronicus, Névrodermite, etc., the most arresting clinical feature is that form of induration to which the names *lichenification* and *lichenisation* have been given by the French school. The accompanying itching is of severe type, often very intense, and doubtless is the most frequent cause of the patient's seeking medical advice. The first case of this kind in which I employed the vacuum electrode was that of a young miner. The lesion was situated in the lumbo-sacral region. An ointment of salicylic acid and oil of cade was applied daily, and the vacuum electrode once weekly. The itching soon yielded to the treatment, and in several weeks the plaque disappeared. The patient has not again sought relief.

My second case was that of an East India merchant, about 40 years of age, who had several plaques about the region of the neck and shoulders and a keratotic condition of both palms. It may be mentioned that I had previously treated his son—a boy about 5 years of age—for xeroderma. The patient was in a depressed condition, having recently lost his wife. During the local treatment he took from time to time such tonics as iron, arsenic, and strychnine. Various preparations of salicylic acid and oil of cade, etc., were employed locally, and eventually ointments of these drugs and accompanying treatment with the glass electrode of low vacuum. The condition was somewhat rebellious to treatment, but ultimately all the body lesions disappeared. The X-rays, however, with boric acid wet dressings proved the most effective in dealing with the palmar condition.

My last case was that of a French lady. Nearly the whole of the neck was encircled by the lesion, which also extended on to the right mastoid area.

Previous to consulting me she had had X-ray and radium treatment, and, judging from the telangiectasis which had replaced portions of the lesion, the treatment had been somewhat heroic. The local treatment consisted of a salicylic acid and oil of cade ointment—the strength of which was progressively increased—and three vacuum electrode séances weekly. At the commencement of treatment the itching was decidedly distressing, seriously disturbing the patient's rest. It was, however, rapidly alleviated after a few applications of the electrode, and somewhat later the induration began to disappear. The patient is now on a visit to the south of France, and at the time of leaving was almost well. Unfortunately the telangiectases persist. It might be suggested that the induration was part of the result of irradiation. It was, however, undoubtedly that clinical variety known as lichenification, and not the keratotic condition resulting from excessive irradiation. The general treatment consisted of careful regulation of the diet, the exhi-

bition of alkalies, and the free drinking of Vichy water.

To sum up, careful regulation of the diet, the adoption of that mode of medical treatment suggested by the general condition of the patient, together with the use of ointments of salicylic acid and oil of cade in progressively increasing strength and the application—sufficient to produce a transitory erythema—of a low vacuum electrode twice or thrice weekly, will, I believe, in most, if not all, instances clear up the condition.

PRELIMINARY LARYNGOTOMY IN OPERATIONS UPON THE TONGUE.

By G. P. NEWBOLT, F.R.C.S.ENG.,
Hon. Surgeon, Royal Southern Hospital, Liverpool.

It is only after carefully noting the results of his work for several years that a surgeon decides on a definite plan of action. If we take up a surgical treatise and read the accounts of the different operations performed on the tongue, for instance, the result of our study will most probably be absolute confusion; and the same remark applies to the descriptions of operations on the rectum, to gynaecological operations, and to operations for hernia, cleft palate, etc. It is only after we have performed the various operations described that we come to a definite conclusion. Unfortunately, cases of malignant disease of the tongue coming to the hospital out-patient room are usually seen in the later stages, and any operation which is performed must be of an extensive nature. If these cases are to be operated upon with any chance of success, it is essential that the surgeon should see what he is doing, so that he may cut widely beyond the growth. If the operation field is obscured by hæmorrhage, or if the anæsthetist gets in the way, he cannot do this. It is no good doing a brilliant operation on a case of malignant disease of the tongue; for if a portion of the disease is left behind, the operation had better never have been done. Again, there is great danger of blood getting down the trachea and setting up a condition of septic pneumonia. How, then, can we best avoid these occurrences? This question has been answered by one of our leading authorities, Sir H. Butlin, for he, I believe, nearly invariably did a preliminary laryngotomy in cases of extensive operations on the tongue. What are the advantages claimed for this method of operating? They are the following:—

- (1) The surgeon can see exactly what he is doing, and there is no need to hurry.
- (2) No blood gets down the larynx.
- (3) The anæsthetist is not in the surgeon's way.
- (4) It is not necessary to have a skilled anæsthetist, though he is always to be preferred.

During the last four or five years I have done a good many operations on the tongue and jaws, and in the majority of these have performed preliminary laryngotomy. I may as well say at once that I do not advocate this operation in early cases of cancer of the tongue, where the growth is well forward and easy to get at.

The operation is a simple one to perform after an experience of two or three cases.

Having marked the thyroid prominence and the cricoid cartilage, a median incision is made of about an inch long. The sterno-thyroid muscles are separated, and a vessel may or may not need securing. The crico-thyroid membrane is next exposed, and the knife entered transversely and close to the upper edge of the cricoid cartilage so as to avoid the crico-thyroid vessels. The dilators are put in and the points turned upwards; on

opening the blades it is easy to slip the laryngotomy tube in below them. A silk-worm gut suture on either side fixes the tube, and two in the skin, passed deeply, control any superficial bleeding and also hold the tube. In doing this operation it is necessary to open the larynx with the quick thrust of a sharp knife, otherwise the mucous membrane will be pushed in front and will give trouble. At first I used two sharp probes pushed through and then separated, and this is the plan adopted by Sir H. Butlin. In one case I divided a small branch of the crico-thyroid artery which ran directly downwards, but I was able to secure it at once; and I have notched the cricoid cartilage; but since the knife has been lateralised I have had very little trouble, even in patients with very thick necks. The tube can be removed directly the operation is completed, or some hours or days later. Generally speaking, I remove it the following morning. The wound heals without much trouble if carefully dressed. The anæsthetist can now take his position away from the mouth, and the surgeon has the field to himself. Chloroform is given on a piece of lint held over the laryngotomy tube. The tongue having been drawn forward, the string sponge is placed well down the fauces, and no blood is likely to descend into the trachea. The growth on the tongue is removed with scissors, vessels secured, and the parts examined, more tissue being removed if necessary—and it is sometimes necessary. I maintain, then, that the best way of operating on extensive malignant disease of the tongue is by doing a preliminary laryngotomy and removing the growth with scissors. The one exception I make is where the growth is so far back that the sponge plugging the fauces cannot be placed, and here I should do a high tracheotomy and plug the trachea, or use a Hahn's tube. We now come to another condition—that of malignant disease of the upper jaw. In removal of the upper jaw the hæmorrhage is usually very profuse; the patient is better in the elevated position, and it is essential for the surgeon to see what he is doing. With the aid of the laryngotomy the anæsthetist is removed from the field of operation, and the growth is excised more readily. In some very hæmorrhagic cases plugging the cavity left by the removal of the jaw may be necessary, and the tube can be left in the larynx until the plugs are removed. In a desperate case which I operated upon lately, the question arose whether the patient would stand the operation, as she was anæmic and feeble. I did a preliminary laryngotomy, and also exposed and clamped her common carotid on the side of the disease; by these methods her upper jaw was removed with success. Had they not been adopted, I feel sure she would not have left the table alive. Of course, I have operated without taking these precautions. I removed the left upper jaw from a patient who was suffering from malignant polypi affecting the antrum and nostril some eleven years ago. No laryngotomy was done, and this patient is still quite well, and was seen the other day by the dentist who makes his plates.

A very unfortunate case was one in which the patient had an epithelioma involving his soft palate. He was given chloroform through a Junker's inhaler. The apparatus, however, was not working properly, and he received a dose of pure chloroform down his larynx. The anæsthetic was at once stopped and he was inverted, but symptoms of acute inflammation of his lungs came on, and he died forty-eight hours after operation. *Post mortem* there were gangrenous patches in the right lung, evidently due to the direct irritation of the chloroform. Had preliminary laryngotomy

been performed this would never have happened. The growth was easily removed with a pair of scissors. I may here introduce the argument that a hasty laryngotomy has been done many times in cases in which the preliminary operation would have saved the patient from running a great risk or even from death. Erichsen says, "The most serious accident is when the gag slips whilst free hæmorrhage is going on. In a case of this kind I had to perform laryngotomy, as a coagulum formed in the pharynx before the vessel could be secured." Again, when the whole tongue is removed, the laryngotomy saves the patient from the risk of the stump falling back, and from the agony of having it forcibly pulled forward; even if the tube is left in for two or three days no harm results. Though a strong advocate of this method of operating, I have tried all the others except the trans-hyoid pharyngotomy advocated by Carless. One of the best results I ever had was that of removing the right half of the tongue with scissors after a preliminary ligature of the lingual on the same side. On the fifth day this patient had a sharp secondary hæmorrhage in the early morning, apparently from his ascending pharyngeal artery. I cut down and tied his external carotid, at the same time removing some glands I came across. This man is still well, I believe, and it is nine years since his operation.

A word about hæmorrhage. This may occur at the time of operation or afterwards. In the first instance, it can be controlled by drawing the tongue forward by means of the silk, or by pressing it forward with a finger placed behind the root. In two cases I have had of reactionary hæmorrhage occurring after the return of the patient to the ward, one required ligature of the external carotid, and in the other the bleeding was stopped by fixing a gauze pack along the floor of the mouth and sewing the tongue over it to the side of the jaw. A solution of adrenalin will stop oozing from the cut surface. I have mentioned the case of secondary hæmorrhage in which I tied the external carotid. I do not believe in ligature of the linguals before removing the tongue, because I had hæmorrhage after it, and the laryngotomy renders it unnecessary. The only time I should think of doing it would be if I was removing the glands first.

I now propose considering some of the methods advocated for removal of cancer of the tongue, and the first I shall deal with is that of splitting the cheek in order to expose a growth in the posterior part of the tongue. I have performed this operation several times, and have also combined it with a laryngotomy. In one case, on account of the contraction of the man's mouth caused by a burn, it was impossible to operate in any other way. This method gives a good exposure, but leaves an ugly scar. There is the danger of infection of the wound, and in one of my cases a growth appeared in the divided cheek. I remember the same thing occurring in a case under my care many years ago. Splitting the jaw in the middle line gives good access to growths at the anterior part of the tongue. This operation, which is commonly known as Syme's operation, is, however, a very severe one, and there are a great many objections to it from my point of view. In the first place, I have found that the hæmorrhage is just as troublesome as when the scissors alone are used. In the second place, there may be and often is trouble with the divided jaw; it may be that it does not unite, there may be necrosis, and, worst of all, the growth may develop in the divided jaw. I had a case of this sort in my own practice, and a big

tumour formed in the anterior portion of the jaw, though there was no recurrence in the tongue or floor of the mouth. I lost a patient from this operation on the eighth day. The man suffered from profound shock at the time of operation, and though he rallied to some extent he showed no promise of getting well. I understand that Professor Kocher adopts this method now almost invariably, having given up his original operation. This consisted in a dissection of the submaxillary region, with removal of the submaxillary and the lymphatic glands, the diseased half of the tongue being removed through the mouth or through the opening thus made into the floor of the mouth. The advantage claimed was the removal of the disease at one sitting, but this was counterbalanced by the risk of infection of the wound. The fact that its originator has given it up is sufficient to condemn it, and, after doing it several times, I came to the conclusion that other methods were better.

As things are at present, I have no doubt that if cancer of the tongue is seen at its early stage when it can be widely excised, and if the glands on the same side of the neck are also removed, the patient has a good chance of remaining well for some years at least.

There is still some difficulty in persuading patients to undergo the second stage of the operation. The tongue having been removed, they usually want to put the second operation off, naturally concluding that it will be as painful as the first was; and, as there is no doubt that excising of the tongue or a portion of it is a very painful operation, one is not surprised at this. The question of doing both stages at once, I think, may be put out of court, as it adds to the risk, and the glands will probably not be thoroughly removed.

I have removed the glands before doing the operation on the tongue, but patients do not like it, and will often refuse to have it done. In one case in which I performed it, the man only worried until the tongue operation was completed, and he was quite unable to understand why his neck had been operated upon. If the glands are at all palpable, especially in the superior carotid region, it is an open question whether much good will be done, and the cases in which they cannot be felt at all are those in which the operation is chiefly indicated. Practically I have found that the submental and submaxillary glands can be well cleared, but when the glands lying on the carotid and running up to the parotid region are involved, very little chance of dissecting them out remains. The internal jugular vein has often to be cleared away, the pneumo-gastric nerve can usually be separated, but in spite of the fact that arteries are not supposed to be involved, this is not always the case. Now, though the carotids may be treated with scant ceremony in young people, it is not so with elderly individuals like those often attacked by cancer. In one man I had either to remove a piece of his common carotid or leave the growth. I tied the carotid and removed the growth, but he got cerebral thrombosis with paralysis of the opposite side, from which he died. This was a case in which an epithelioma had been removed from the lip two years previously. In another case occurring in a young man who desired to have a mass of malignant glands removed from the left side of his neck, having pointed out the risk, I cut the growth away, with the artery, vein, and nerve, all being involved in the growth. Beyond some hoarseness he suffered very little inconvenience, and made a good recovery from the operation, though it is not probable that he will live for any length of time, as it was a recurrent growth when I operated. In a patient, *æt.* 41, I

ried the right common carotid and internal jugular vein, and cleared the glands from that side of the neck on June 30th, 1910. On March 9th, 1911, I cleared the left side of the neck, tying the internal jugular vein. No bad symptoms followed, but the growth returned in the side of his pharynx. One can only look upon these cases of cancer occurring in men of forty as peculiarly hopeless. Again, when there is a big ulcer on the floor of the mouth, it is often very difficult to make out the extent of the disease until the patient is under an anæsthetic. I have a man under my care at present whose growth seemed inoperable until the parts were relaxed, when I found that there was a space between the jaw and the growth, a point one could not ascertain beforehand on account of the extreme tenderness of the parts. However, if the growth is at all extensive, and if the glands are palpable, the prognosis is very bad, and we only operate because there is at present nothing better. There is always the chance of a brilliant result; the mouth is kept cleaner as a rule after operation, and the mortality is not a heavy one as far as operation goes. Moreover, patients recover very quickly from operation; they get up sometimes on the third day, and though mutilated are able to make themselves understood by those accustomed to them. I cannot understand why, in these progressive days, we do not get cases of malignant disease of the tongue earlier. The first thing that must cross the mind of any doctor who is asked to see an ulcer of the tongue must be "Is this cancer?" and what does he do? In the first case he prescribes antisyphilitic remedies and his patient's chance goes. The only reasonable method is to paint the ulcer with cocaine and snip a minute bit off for examination. If it is clearly put to the patient how necessary it is, he will submit, and in any case the doctor has done his duty. A case now under my care was treated for many months with potassium iodide, and though I have operated upon him it was only as a last chance. In conclusion, I can only repeat that early diagnosis, wide excision, followed by removal of the glands in the neck, offers a reasonable hope of recovery in cases of cancer of the tongue; and where the operation is likely to be extensive, or where the posterior portion of the tongue is affected, preliminary laryngotomy is of the greatest value. I fear malignant disease of the upper jaw is still a very hopeless condition, and the operation of removal a severe one; but I still think these cases are worth operating on if seen in the earlier stages. It is wonderful how little deformity results, and what can be done by the dentist. If the cheek itself has to be sacrificed, a good deal can be done by plastic methods, and I have at present under my care a man whose cheek I am building up by means of a flap taken from his neck. When all is said and done, and we look back upon our cancer results, I fear that though we may relieve many we actually cure but few; and every surgeon looks forward to the time when a cure may be found for a disease which baffles medicine, and though many ingenious operations have been devised for its cure, the surgeon feels that in undertaking them, in the majority of instances, he is predestined to failure.

THE Departmental Committee appointed to report upon the revision of the Poor Law Orders consists of Sir S. B. Provis, Sir J. S. Davy, Mr. W. T. Jerred, C.B., and Mr. Thomas Smith, with Mr. H. W. S. Francis as secretary. The draft Order described in *The Times* recently has been referred by the Committee to various bodies interested in the Poor Law, and has not yet been officially issued by the Local Government Board.

RETIREMENT OF PROF. HEUBNER.

THE announcement is made that Geh. Rat. Professor Heubner will vacate his post as Director of the Kinderheilklinik of the Charité, on the attainment of his seventieth year, which will be at the close of the present Semester. The announcement has been received with the general regret that might have been expected of all those to whom the name of Heubner is familiar as one of the most outstanding figures in the realm of medicine of the present day. We may perhaps be permitted to express the hope that in his retirement the distinguished Professor will be able to enjoy all the amenities of a vigorous and healthy old age.

MESOTHORIUM.

In the discussion that followed the reading of the paper on "The Action of Mesothorium," by Hr. Sticker, Hr. Pinkuss (amongst others) took part. He said he would only briefly relate his experiences with mesothorium in inoperable cancer. As already reported to the Society in March last, on the occasion of Hr. Bickel's address, he had observed good effects from irradiation of superficial returns of cancer. He then showed a woman who had several ulcerated nodules after a second operation for cancer of the breast, and where a marked cicatricial process had taken place under the influence of the mesothorium rays. Since then the cicatricial changes had become still more marked. This favourable influence, however, he had only observed in ulcerations that were superficial, and not in any cancerous nodules that lay at all beneath the skin; these, in spite of the raying, developed in the usual manner. As regarded *technique*, he would only say that he made use of very active capsules, and kept up the applications for an extended period. Now, as on the previous occasion, he could only say that mesothorium could only be looked on as an aid in the treatment of inoperable cancer, where surgical measures were no longer practicable, but that in such cases they were of equal value with X-rays and radium. In cases where he had used mesothorium in sub-vaginal recurrences of cancer he had observed a diminution in size for a time, or there was an arrest of growth for a longer or shorter period, but in the end he was not able to prevent a further advance of the disease, or the development of metastases. He must say that he almost envied Hr. Sticker his cases in which the development of metastases was prevented, his own cases had not been so fortunate.

Hr. F. Krause had sent for a patient that the meeting might see him, but he had already been given a dose of morphia, so could not come. He first saw the case last January. The man then had a small sarcoma on the shoulder, which could have been removed without any necessity for removing the arm, and the extremity would have been a quite useful one. The day was fixed for the man to come into hospital for the operation, when he underwent radium treatment instead, not only X-rays, but treatment by injection of radium, and not by an unknown or inexperienced practitioner, but by one of the first rank in Germany, so that the treatment would be carried out in the best manner possible.

He would have liked to show the man. In the morning he would unfortunately have to remove the whole shoulder girdle, the clavicle, the scapula, and the whole upper extremity; the tumour had grown so rapidly that it was now the size of a man's head. The gentleman had told the patient when the tumour softened that this was favourable, the softened mass was withdrawn by an aspirator. Every surgeon knew the condition, and knew that if such a tumour softened it was the more dangerous. A soft sarcoma was a hundred times more dangerous than a hard one, as it grew more quickly and metastases formed the more readily.

In view of such cases he must take the firmest stand on surgical grounds, and demand that no tumour that could be operated on should be submitted to either radium or X-rays or mesothorium. It was a step backwards—not to use a stronger expression. It was, however, an advantage to be in possession of such means—to be made use of in their proper place.

Hr. Isaac, who had at first worked along with Sticker, had continued in his own klinik. He had treated quite a number of skin cases with mesothorium, nævi, angiomata, lupus erythematosus, some cancroids, lupus vulgaris, also a case of lupus pernio. They had treated such and similar cases with radium previously, so that they were in a position of being able to compare the effects.

Whilst the application of even a few milligrammes of radium caused a deep destructive effect on the diseased tissues it was quite the opposite with mesothorium. Here a kind of inflammation was set up, which raised the diseased tissue up out of the skin, so that there was frequently a superficial exudation, and not infrequently the formation of vesicles. This inflammatory action was excessive when the dosage was large, so that the action had to be stopped unless one was ready to run the risk of doing a considerable amount of mischief. This tendency of mesothorium to act exudatively had the effect of causing cancroids to heal quickly, whilst in lupus erythematosus and nævus angiomaticus the effect was not so good.

Hr. Saalfeld said that he had applied carbonic acid snow to the part first to lessen sensibility, and he had found that the effects of both radium and mesothorium were increased by it.

Then for the protection of surrounding parts, for the sake of simplicity, he had used Belgian and Japanese coins which had a small hole through the centre.

Hr. Schönstadt wanted to know in how many of the cases the treatment failed, and in how many cases of carcinoma it had been successful? A large number of relapsing cases recovered without any special treatment, as any one knew who treated large numbers of cases. A few successes in treatment were not a proof of the value of the remedy.

AUSTRIA.

Vienna, Sept. 14th, 1912.

AMTS CONGRESS.

THE Sanitary Congress this year was held in the large hall of the Cracow University, and attended by representatives of all the neighbouring provinces of Prussia and Russia. Czyzewicz, President of the Amtsaerzte of Galicia, welcomed the members to Cracow.

Szarski, in the name of the town, said that they had twelve medical inspectors for the schools of Cracow alone, and had recently added a modern infectious hospital.

Jurasz raised the subject of "Scleroma," giving its history, pathology and clinical aspect. He thought the principal infection spread from Eastern Galicia and South Eastern Russian provinces and gradually extended over Austria. The disease, after affecting one member of the family, slowly spread involving a whole town or district. It was necessary, under these circumstances, that the State should take more energetic measures to check its progress by systematic regulations and stringent notifications, as well as an exhaustive investigation of the pathogenesis of the disease, so that the spread of the plague could be checked in its early course. He then proposed a few regulations for the State, such as:—All the Crown lands of Austria giving statistics once a year of the places affected, with the number and severity of the disease; that central stations for proper treatment and isolation be instituted; that an international "Scleroma" conference of representatives from interested countries, such as Austria, Hungary, Russia, Prussia, Switzerland, Italy, Roumania and Spain should meet and discuss the subject of chronic and infectious acute forms of the disease and the different treatments adopted.

Haus next gave a history of his twenty years' work

as Amtsaerzt, in the large works of the neighbourhood and drew a contrast between his first engagement twenty years ago and the houses and homes of the workers of the present day. All was done by charity in his early experience, but now humanity prevailed and the social struggle for existence was much alleviated. The greatest difficulty he met with was with the capitalist in abating nuisances arising from effluvia and noxious gases.

Eisenberg complained that Austria was not doing her duty in the research for infectious diseases and bacteriology, both of which were of great importance to the medical officer of health; he thought the State should take an example from Prussia, which has provided institutes for examination and research under competent instructors.

Bory referred to the difficulty of differential diagnosis in typhus and typhoid, both in epidemics and sporadic conditions. In tracing the origin of the disease he was convinced that fleas played an active part in transmitting the germ.

Paul complained that the State did not give the medical officer proper assistance in notification to stamp out these diseases, as he thought it should provide subventions and stringent measures.

Winter proposed a thorough reform of the Public Health Act, of 1870, as it was quite out of harmony with the wants of the present day.

Besides the medical officers of health should have two years more of instruction in theoretical work at the expense of the State.

CANADA.

Montreal, Sept. 7th, 1912.

COCKERELS AND CATS IN MONTREAL.

IT has been frequently a cause for wonder to one who, like myself, has resided in New York, that cats have not been indicted as a nuisance and a menace to health by the progressive Board of Health of that city. These domestic members of the feline tribe swarm in New York, and from the extremely unhealthy appearance of some must be to some extent a menace to health. There are diseases which may be conveyed by cats, and furthermore, in New York at least, they are notorious scavengers. Garbage barrels, often filled with an indescribable mixture of unpleasant odds and ends of food and clothing, are the happy hunting ground of cats, who afterwards go into the respective houses to which they belong, and undoubtedly carry on their bodies and in their mouths filthy, if not infectious, material. City cats, as a rule, are not fitting denizens of a house nor appropriate companions of young children. However, it is not from this point of view that the inhabitants of Montreal have been objecting to their cats, but because they are oftentimes a nuisance in that they make unseemly noises in the night, preventing peaceable citizens from sleeping, and perhaps in some instances predisposing to insomnia. From this standpoint there are few city dwellers who will not sympathise with those of Montreal, for who among us has not been at one time or another kept from sleep by these unmelodious nocturnal disturbers? But in Montreal it is not even the cat who is the worst offender. It seems that many of the residents of the city on the St. Lawrence possess rural tastes, and although living in the heart of the Canadian metropolis, gratify their taste by keeping cockerels, hens, geese and turkeys. I was struck when reading the headlines of a Montreal daily paper the other day by the words "The rooster nuisance continues, and the Medical Officer of Health means to take a hand." Now, I have lived in different parts of America for many years, but I must confess I had to think twice before the identity of the rooster with the domestic cockerel impressed itself on my understanding. When I did appreciate the point, I also fully appreciated the good sense of those who objected to this form of music in the early hours of the morning, and also the readiness of the Medical Officer of Health to allow that the continuous crowing of a strong-lunged cockerel in the hours of dawn should constitute a nuisance. Moreover, it is asserted by a sufferer who lives in a

residential street in the centre of Montreal that a neighbour in a flat under him not only keeps hens and a vociferous rooster, but he has turkeys and geese, and is now talking of getting a parrot. As Dr. Laberge, the Medical Officer of Health, pertinently admitted, that while a rooster was all right enough in a farmyard, it was a different matter when he was transferred to a residential street where the back yards were the size of billiard tables, and where every cock crow resounded like a trumpet through the near-by row of flats. Although Dr. Laberge is thus sympathetic and willing to invoke the strong arm of the law to abate the nuisance, he is not yet certain whether the owners of cackling hens and crowing roosters in a residential street can be compelled to get rid of them—that is, so long as they are kept in a sanitary condition. If a test case be brought it is to be hoped, for the sake of humanity at large, that the decision may be against the owners of the roosters.

MONTREAL'S BIRTH AND DEATH RATES.

Montreal has for long been distinguished among the cities of the civilised world for its extremely high birth-rate, but it has been likewise notorious for its appalling death-rate. Last year the birth-rate of Montreal was 37.49 per 1,000, and the death-rate 21.19, which represents a gain in births of 1 per cent., and a decrease in deaths of one and a fifth per cent., as compared with the record of the year preceding. Dr. Laberge, City Officer of Health, recently announced these figures, which will be included in his annual report for 1911, shortly to be issued. The city's population in 1910 was 455,800, and in the present year about 470,000. Dr. Laberge is of the opinion that the decennial census should be replaced by a census every five years, and thinks it would be a good idea if Montreal could make some arrangement with the Dominion Government to that effect. Montreal has had an unsavory reputation for unhealthiness, but is now rapidly improving from the health standpoint. In 1872 the death-rate was 37.36 per 1,000. In 1878 the rate was brought down to 30.51, and since that time, with the exception of the years when small-pox was raging, has been going down steadily. There is, however, as is acknowledged by all, room for great improvements in the sanitary conditions of Montreal. The sewage arrangements and water supply are not so good as they might be, although work in these directions is now going on. Montreal is badly paved and there is much overcrowding, more overcrowding by far than is consistent with good health.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

JAMES MURRAY'S ROYAL ASYLUM, PERTH.—In his annual report, Dr. Urquhart, Physician Superintendent gives the average admission rate since 1865 as 53.13; for the year that has just passed there have been only 27 admissions. Fifteen of these were regarded as curable, and of them eight have recovered or are convalescent. In Dr. Urquhart's opinion the alcoholic patients received are really mentally defective—the insane constitution precedes the drunkenness and causes it. The general recovery rate of the asylum during the years 1865-1911 is 34.33. Last year it was 22.2, as compared with 49.1 in the preceding year. In his general remarks on the Institution's progress, Dr. Urquhart expresses some regret that more has not resulted in the way of treatment from recent researches, and he speaks of the disasters which may befall the Royal Asylums of Scotland through promised legislation. The district asylums were lately provided with pensions, thereby putting them on an equality with similar institutions in Scotland and England. No sooner has this become law than an Amending Act is threatened, which reduces these hospitals for mental diseases to the level of factories in respect of hours of work. The Royal Asylums require no such enactment, nor, indeed, do the

District Asylums. However suitable that may be for the vast asylums of London and Lancashire it is unnecessary and adverse to the interests of patients and staff in every asylum in Scotland.

ROXBURGH, BERWICK, AND SELKIRK DISTRICT ASYLUM.—The report of this asylum for the year ending May 15th, 1912, has now been issued. A considerable part of Dr. Carlyle Johnson's report is concerned with the effects of recent legislation. Although the Asylum Officers' Superannuation Act has only been in force for two years, two Amending Bills are already before the Commons. The Act has been difficult to interpret on account of the obscurity of its terms, and it has entailed hardship on those it was intended to benefit. The "Asylums Officers' (Employment, Pensions and Superannuation) Bill," presented by Viscount Woolmer in February, 1911, is of a hybrid character. While embodying several commendable amendments, it introduces the contentious proposition of fixing the hours of employment of all asylum attendants. While the labours of a Select Committee have improved it, it still involves the new and questionable principle—viz., that the Legislature should fix the hours of work of employees of local authorities. In Scotland, whatever be the case with regard to English asylums, there is no call for this; the nurses and attendants are satisfied with their lot, and realise the efforts made for their comfort; superintendents, on the other hand, appreciate the loyal services of their nurses and have their interests keenly at heart. Hours of duty have been shortened and leave increased, but legislative restrictions, which would lead attendants to regard their legal right as of the first importance and their duties to patients as of secondary importance, are much to be deprecated. If the schedule of hours, recommended by the Select Committee, is imposed, the result will be that in some of the Scottish asylums the hours will be longer than they are at present. A second Bill, the "Asylum Officers Superannuation Bill," has been introduced by the promoters of the principal Act. In this an attempt is made to remedy the anomalies of the Act, without introducing the contentious features of Lord Woolmer's Bill. It is now proposed that every permanent servant shall be pensionable, and that the definition of "first class" established officers and servants shall be considerably extended. The measure will effect a final settlement of the disputes which were aroused by the original Act, and it is hoped that it may pass into law.

THE LUNACY (SCOTLAND) BILL contains one clause which appears to be hurtful to a particular class of the community. This is Clause 3, which provides for the reception of private patients in district asylums. For long it has been the practice to receive into the Scottish district asylums, provided there was accommodation over and above what was required by the pauper patients, private patients at low rates of board. Thus a class of patient was catered for who could afford to contribute towards his maintenance and thus escape the stigma of pauperism, but who could not afford to reside in a Royal Asylum. Under the ægis of the commissioners and superintendents such private patients have enjoyed certain privileges of board and accommodation, as compared with the patients borne upon the rates. The Act proposes to limit the charge to be made for such patients to a sum not exceeding £10 above the amount paid for pauper patients, and, in addition, it is provided that such private patients "shall have the same accommodation, food, and attendance in all respects as the pauper patients." As Dr. Johnstone says, "It is difficult to understand how such a harsh, retrograde, and inconsiderate proposal can have been allowed to find its way into print." It relegates the poor professional man, the village shopkeeper, the small farmer, the decayed gentlewoman, afflicted with mental disease to the status of pauperdom, and, instead of lightening the restrictions which a generous administration has established it enhances them and condemns the patients to pay a prohibitive rate for the privilege of being treated in all respects like a pauper.

HONOUR TO SIR WILLIAM TURNER.—His Majesty the

Emperor of Germany has conferred on Principal Sir William Turner, K.C.B., the Insignia of Knight of the Royal Prussian Order, *Pour le Mérite*, in the department of Science, in recognition of his eminence as an anatomist. The number of Knights of the Order is strictly limited, and the death of Lord Lister in the spring of the year having caused a vacancy Sir William Turner has been selected to fill it.

BELFAST.

REGISTRATION OF MIDWIVES.—At the weekly meeting of the Public Health Committee of the Corporation held on the 12th inst., a deputation from the British Medical Association (Belfast Division) attended in reference to the enforcement of the Local Act, 1911, as concerned the provisions for the registration of midwives practising in the city. Sir John Byers and Dr. H. J. Ritchie, addressed the Committee at length, on behalf of the deputation, and explained that the matter was one of great importance not only to the public, but also to the medical profession. They urged that in the framing of rules and regulations under the Act the members of the profession should be given an opportunity of stating their views, and also that they should have representation on the committee appointed to deal with the question.

SANATORIUM TREATMENT AND THE INSURANCE ACT.—At a meeting of the Londonderry Public Health Committee held last week, a report was received from a sub-committee, which had been considering the question of Sanatorium Treatment. They reported that they had been unable to come to any agreement for joint action with the County Council, and they recommended that a site be selected on Foyle Hill and plans prepared for the erection of a temporary building to be used as a sanatorium and tuberculosis dispensary, and also that a tuberculosis medical officer be at once advertised for at a salary of £350 per annum, to devote his entire time to the duties of the office. Councillor Dr. McCaull said that he would like to see the duties of the medical officer defined before any appointment was made. It would be impossible for them to get a man of experience, and who had proper qualifications, and who would be of advantage to the city, and consulted by other medical men, at a salary of £350 a year. If the medical officer were a junior doctor, without experience, they might not expect the senior members of the profession in the city to consult him. Speaking for himself, he would certainly not do so, and he believed his colleagues would take the same course. If they, on the other hand, wished to procure the services of a thoroughly competent senior qualified man they would not get such an official for the salary suggested, so that if they advertised the sum mentioned in the report, the result would only be harmful, instead of helpful. The Mayor said that Councillor Dr. McCaull's remarks were very wise and thoughtful, and, after some discussion, it was decided to postpone the matter for further information.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE TUBERCULOSIS CAMPAIGN IN IRELAND.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The long, well-written articles of Dr. Agnew, of Lurgan, about the White Scourge should, I think, cause medical men deep thought. Unless the money be usefully spent it might as well not be given. I will take his suggestions—

A Sanatorium for each Province.—The general consensus of opinion is that a sanatorium is of great use in educating patients how to live and how to avoid infecting others and is of benefit to poor people, who, while resident, get good food and proper hygienic treatment, but that the curative effects are greatly overrated by the public, and that thus false hopes are given to patients and friends. Owing to distances, if

there is any good to be derived one for each province is insufficient.

A Tuberculosis Dispensary for each County.—What advantage could consumptives derive from one dispensary, say in Donegal? How could a patient, living on the confines of the county at Bundoran, Ardara, Tory Island or Gwedore on one side, or Lifford St. Johnston or Derry on the other, or in the central parts, which I need not name, attend at frequent intervals any dispensary, no matter in what part situated, and how much infection would be spread in travelling? This brings us to the only practical suggestion—namely, domiciliary visits. Then the question comes, who is to undertake the domiciliary treatment, and there is only one answer, the dispensary doctors, and they are quite capable, their only handicap being the homes of the poor, where it is impossible to isolate or properly feed a case. I have recollections of having had to treat cases in badly built, damp, dark cottages of one or two rooms, where a numerous family had to find sleeping accommodation somehow, and unless legislation can compel the patient to go away to a sanatorium or other isolation place for the rest of his days, isolation is impossible. I cannot see what good a chief tuberculosis officer could do, but I can see a great evil that he will do. He will in the eyes of the people depreciate and lower the status of the medical man in attendance, and they will get to think that their doctor has not the ability to treat them and that the tuberculosis officer has special knowledge and can work miracles. Clinical auscultation, as Szendeffy states, is yet the chief means of diagnosis, and surely the doctors who are seeing such cases daily in their work are the most reliable for spotting the disease and to undertake its extermination, but to do so two things at least are required—small isolation homes in every one or two combined dispensary districts, and legal power to send the sufferer to the home and compel him to remain there, but I fear this is a counsel of perfection that is impossible. Instead of appointing a chief tuberculosis officer, a few men of leading might be nominated as consultants for each district as was done in London during small-pox epidemics, whose services could be had when the attending doctor wished for a second opinion. To exterminate the disease the treatment of cases is, I take it, of less consequence to the country than its prevention. Your report from Belfast of the number of tuberculous cattle found in the slaughterhouses points, I think, to a use that a good deal of the money might be put to, as if it were possible to free the milk and beef from tubercle a considerable source of infection would be abolished. Prof. Whitla, in an illuminating address some four or five years ago, gave some instances of infection by milk from a prize-taking cow. I have great hopes that the improved cottages, erected under the Labourers' Housing Act, will do much to stamp out the disease, but, of course, they are comparatively few, and unfortunately the majority of cottages are far from ideal. Exhibitions, caravans, lectures and literature will do much, but isolation, good housing and proper feeding are required, and my only object in writing this letter is to beg of those who have the country's good at heart to spend the money usefully and practically and not to fritter it away on highly-paid officers, whether medical or otherwise.

I am, Sir, yours truly,

JAMES HAMILTON, M.D., M.CH.

Chelsea, September 15th, 1912.

EIGHTIETH BIRTHDAY OF LORD ROBERTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—On the last day of this month Field Marshal Earl Roberts will attain the age of 80 years, and it is proposed to make a presentation to him on that occasion. Subscriptions are being collected by the branches of the National Service League throughout the Kingdom, and Lord Roberts has intimated that all sums not ear-marked to provide a personal gift for

himself will be utilised by him in furthering the adoption of universal military training by this country.

It is probable that many persons, who are not members of the National Service League, may wish to join in paying a tribute of respect to our veteran Field Marshal, and we desire to inform them that the smallest sums will be gratefully received and acknowledged by the secretaries of the Dublin branch of the National Service League.

We are, Sir, yours truly,
R. K. CRAWFORD,
J. B. STORY,

Hon. Secs. National Service League, Dublin.
6 Merrion Square, Dublin,
September 9th, 1912.

[As a journal which has, since its birth more than 73 years ago, been closely identified with Irish life, we venture to urge our readers to use their influence in supporting the proposed memorial to a great fellow-countryman.—ED. M. P. AND C.]

TUBERCULOSIS: A SANITARY INSPECTOR'S VIEWS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your editorial note on the *Westminster Review* articles concerning tuberculous cows leads me to write to you. My card enclosed will tell you that I am a sanitary inspector in a semi-rural district amidst manufacturing towns. I have held my position for upwards of twenty years. I have kept my eyes and ears open. I have been a constant enough reader of medical papers, including yours, and through friends I get a sight of leading papers, even *The Times*, now and again. My slight scientific knowledge and my experience have taught me many things. Among other things I have learnt that a sanitary inspector dare not, by advice or action, go beyond the wishes of the authority whose servant he is. If he does, he will probably be got rid of on the first opportunity, or his miserable stipend will be docked, or he will risk the loss of a retiring pension. Men of my length of service and age, with no possible other career open, are obliged to keep our mouths shut whilst trying to do our duty so far as we can.

I can see clearly that measures for the prevention are of far greater importance than the treatment of tuberculosis; but this fact does not seem to have been clear to Mr. Lloyd George and his advisers in framing the Insurance Act. And it is clearly much easier to prevent than to cure the disease. Great part of the money put aside for sanatoria, and such like things, ought to have gone towards prevention. In prevention the housing problem comes first. The people who live in slums and in slum dwellings, the latter as common in rural as in urban districts, supply the great bulk of victims to tuberculosis. This evil might have been very much diminished under existing laws; but, as I can testify, the laws have been largely in the hands of the very persons concerned in breaking them. These men often seek seats on the local authority with the intention of protecting themselves and their friends from interference. This is the fault everywhere of the better classes. Men of education and position in sufficient numbers cannot be found to take part in local government. If laws were properly administered, it would be impossible to find Local Government Board reports such as are now quite common. One of these is quoted in a leader in *The Times* last week. I read that in a certain rural district pigs are kept in the same sheds as milch cows, and that in a patched-up shed, containing ten cows, unventilated save through doors, in which milking was being carried on, the air was almost unbearably hot, as well as offensive. "The milker's face and arms were steaming with sweat, drops of which could be seen steadily falling into his milking pail as he worked." As regards foldyards, the general condition is reported to be bad. Manure is accumulated in vast quantities close to the openings of sheds. "In two instances I saw cows plunging through this in order to enter the sheds to be milked, their udders trailing in the filth."

I can confirm the writer's statement that in this description there is nothing exceptional. There are, of course, dairies in which cleanliness is found, and in which care is taken of the milk; but even in these, as a rule, there is no exclusion of cows affected with tubercle, so long as it does not occur in their udders, and we know, from the report of the Royal Commission, that its presence is dangerous to the consumer. As long as the conditions described exist, attempts to cure tuberculosis will be condemned to failure.

The housing problem, enforcement of laws for the prevention of insanitary dwellings, the stamping out of tuberculosis in milch cows, and prevention of the sale of tuberculous flesh of every sort seem beyond doubt the first things to call for attention, and local authorities, when necessary, should be compelled to do their duty.

I am, Sir, yours truly,
"SANITARY INSPECTOR."

THE POSITION OF DENTISTRY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The Dental Profession is under a great debt of gratitude to the MEDICAL PRESS. It has never forgotten the claims of Dentistry as a legally recognised medical speciality. It has never omitted to insist upon the right of Dentistry to be duly considered in all projects of medical law reform. In your last issue you print an excellent letter on the subject by "An Occasional Correspondent." With every word he writes I agree. He has, however, not stated the fact that the failure of dental legislation has, so far as it could, injured the speciality and the public relatively and comparatively to a far greater extent than the failure of the Medical Acts. There are now a greater number of unqualified than of qualified dentists. The unqualified men are either surgically uneducated mechanics, or ignorant quacks of a more or less fraudulent type. The harm they do falls mostly upon the poorer classes. The wealthier people, advised often by their doctors, select qualified men. The victims of the quacks are to be found in numbers among hospital patients; and now that so much attention is being given to "septic mouth," they are constantly being sent to the dental department. It is amazing, for example, to see the number of wretched women whose health is being injured by dental disease. I have just seen such a case. The upper front teeth, being lost, and appearance being of importance in her calling, the woman applied to an advertising firm. Beneath a large denture was found the more or less completely necrosed roots of a dozen teeth, each the centre of a chronic foul abscess. The amount of pus being swallowed daily in such a case is enough to account for serious constitutional disease. Examples by the score of similar cases could be cited. It is quite certain that no qualified dentist, not being a completely heartless rogue, could deal with cases like these in such a fashion; but this is the rule with the unqualified practitioner, who is either merely ignorant or callously dishonest. The cases in which artificial teeth can be properly inserted without preliminary treatment of remaining decayed teeth are not one in a thousand. The quack makes his money by supplying artificial substitutes without surgical consideration of any kind. The situation of men entering practice is very hard. I have a letter before me from a former pupil. He has full medical besides the dental qualification. He made himself a thorough mechanic first of all, and his education filled seven years. He began practice in a semi-rural district having a small town nucleus. He has to compete with two resident local unqualified men, and with three quack firms who visit the town periodically. All these people advertise "dental surgery," "dentistry," and so on, and make the usual fine promises. They get the greater part of the country people who need artificial teeth, and gain big fees from many. The qualified man cannot advertise nor puff himself. To the detriment of the public he is thus robbed of his legitimate practice; and although personally and professionally on a level with

his medical colleagues in the district, he is looked upon socially more or less askance, as "merely a dentist" by the people of the place. My friend loves his profession, of which he is a master, but says he begins to regret having taken it up.

I am, Sir, yours truly,
"A HOSPITAL DENTIST."

London, September 6th.

OBITUARY.

JOHN E. RANKING, M.D. OXON.

WE regret to announce that on the 11th instant, through his motor skidding down hill, Dr. Ranking, of Tunbridge Wells, met with a fatal accident at Bexhill. The driver of the car, in endeavouring to avoid a woman who was crossing the road, applied his brakes rather sharply, but the tyres failed to hold on the tarred road, the result being that the car ran into the bank and overturned. The driver escaped injury, but Dr. Ranking was thrown out and sustained severe injuries. He died two hours later. Mrs. Ranking was also badly injured, but her daughter, who was also in the car, only sustained a few cuts.

Dr. Ranking, who was somewhat advanced in years, graduated as M.B. of Oxford in 1876, and M.R.C.S. and L.S.A. in 1874. He was educated medically at St. Bartholomew's Hospital, and was one of the best-known practitioners in the county.

DR. R. E. THOMPSON, OF LONDON.

WE regret to record the death of Dr. Reginald Edward Thompson, which took place on September 10th, in his 79th year. The deceased who was the son of Mr. Serjeant Thompson, was educated at Brighton College, Trinity College, Cambridge, and St. George's Hospital. He qualified M.B. Cantab., in 1860, and in the following year he went on a shooting expedition to the far Canadian North-West. A few years later he crossed the Rocky Mountains with the late Dr. W. B. Cheadle. Dr. Thompson subsequently returned to his *alma mater*, being shortly afterwards appointed medical registrar at St. George's Hospital. He soon had the opportunity of becoming acquainted first-hand with typhus fever, an epidemic of which occurred at that time among the inhabitants of the tenements adjoining Sloane Street. A personal sufferer from the disease, he contributed a valuable paper on typhus fever to the first volume (1866) of the St. George's Hospital Reports. In 1869 he was appointed Assistant Physician to the Hospital for Consumption, Brompton, becoming Physician in 1880, a post which he held till 1894, being afterwards appointed Consulting Physician. He was also Physician to the Seamen's Hospital, Greenwich. In 1880 Dr. Thompson was secretary of the Royal Medical and Chirurgical Society, becoming Vice-President three years later. He took the M.D. Cantab., in 1863, and was elected F.R.C.P. Lond., in 1868. He had taken an active part in the life insurance world, and in his earlier days he excelled in music and painting.

DR. H. L. A. BARRY, OF BIRMINGHAM.

AN inquest was held on Wednesday last by the Central Warwickshire Coroner, concerning the sudden death, at the early age of 32, which took place at his residence, Aston Manor, near Birmingham, on the previous Monday. From the evidence given by the widow and by the servant, who found him dead in his chair, it appeared that deceased suffered severely from rheumatism, which affected his heart, and sleeplessness, for which he frequently took sedatives. On Monday he complained of want of sleep, and his widow advised him to take another dose of sedative, but he refused.

The servant said that she found the doctor sitting in a chair. She touched his hand and found it was cold, and thought at first he had fainted.

Dr. Hill Norris, who was called in, said that Dr. Barry was dead when he arrived. A *post-mortem* examination showed no trace of poison. Death was

due to heart failure, induced by chronic alcoholism and accelerated by the taking of the sedative.

The jury found that death was due to heart failure, and expressed sympathy with the widow.

OPERATING THEATRES.

WEST LONDON HOSPITAL.

RUPTURED LIVER.—MR. ASLETT BALDWIN operated on a girl, æt. 11, a four-wheeled market cart having passed over the upper part of her abdomen. On admission shock was present to a marked degree, the pulse was rapid and feeble; there were slight abrasions on the chest, but no other external signs of violence; the chest moved well on both sides. The inner ends of probably the third and fourth ribs were fractured. The lungs were normal, excepting for a few moist sounds. The abdomen was not distended and moved well and there was no marked tenderness and no rigidity; the liver dulness was normal, and there was no dulness in the loins.

On the next day the patient was in a good deal of pain, and there was tenderness in the hepatic region. The abdomen was distended and resistant, though not absolutely rigid. There was a tympanic note on percussion with impairment in the flanks. The breathing was short and jerky, and the girl was very pale, with a pulse of 160.

Mr. Baldwin decided to operate at once. Ether having been administered by Mr. Rickard Lloyd, an incision about four inches long was made in the middle line. Free blood was found in the abdomen, and it was discovered that the liver was ruptured on the right side, the tear being situated on its upper surface. A white gauze roll was stuffed between the tear and the diaphragm and the abdomen closed, excepting where the gauze protruded at the upper end of the incision. The other viscera appeared to be normal. Saline solution was transfused subcutaneously to repair the loss of blood.

Mr. Baldwin said that this was a very instructive case of abdominal injury because it showed what a serious lesion may be present, but when the patient is first seen there may be no indication for immediate operation; this had been the opinion of one of Mr. Baldwin's colleagues, who had seen the child on the day before, soon after admission. When Mr. Baldwin saw her she was much worse, in great pain, with tenderness in the hepatic region; the abdomen was distended and resistant, though not really rigid. In front there was a tympanic note on percussion, but some suspicion of dulness in the flanks. The patient was very pale and the breathing was short and jerky. As far as could be counted the pulse was about 160. On opening the abdomen and getting the hand inside, he pointed out that he could feel an extensive star-shaped rupture on the upper surface of the liver on the right side. As it was quite impossible to suture this, and the child's position was one of extreme gravity, all he could do was to stop the hæmorrhage with tight plugging with sterile gauze. He did not attempt to clear out any of the blood in the abdomen as he was afraid the child might die at any moment. The position of the rupture was high up and underneath the ribs, and the gravity of the patient's condition rendered suturing out of the question. He remarked that hasty examination of the spleen and other viscera within reach showed that they were apparently uninjured. The abdomen was closed with through and through sutures, he pointed out, to save time on account of the urgency of the case.

The patient was in a precarious condition the day after the operation, there was slight bleeding which, however, soon stopped. On the next day there was a slight improvement, no bleeding, but a profuse discharge of bile, which continued for the next three days. On the sixth day the gauze plug was removed. About eight weeks afterwards the patient was convalescent, there being then a rosy yellow discharge from the wound. Several pieces of necrosed liver came away during the next three weeks, at the end

of which the girl was sent to a convalescent home, on her return from which in three weeks she was found to be in good health; the wound was quite healed and there was no ventral hernia.

LITERARY NOTES.

WE have received from the Scientific Press a booklet, entitled "Medical Names for Private Patients, 1912; a Classified Directory with Lists of Medical Consultants," published at the price of 6d. net. We have failed to discover on what principle any of the lists in the book have been compiled. The omissions from the lists of "consultants" are as noteworthy as the insertions, but even had the publication any claim to completeness, it could hardly commend itself to the taste of the medical profession.

* * *

MESSRS. D. APPLETON AND CO. announce for publication this week a new eighth edition of "The Principles and Practice of Medicine," by Sir William Osler, Bart., M.D., F.R.S., entirely re-arranged and re-written. All the sections have been revised in the light of recent advances in medicine, and many new sections have been added. Sir William Osler's book is so well-known that students and practitioners will be glad to learn of the appearance of this new, eighth edition.

* * *

MESSRS. J. AND A. CHURCHILL announce the following new works and new editions:—"Mother and Baby," by Selina F. Fox, M.D., B.S., Senior Physician of the Bermondsey Medical Mission for Women and Children. "A Treatise on Tumours," by Arthur E. Hertzler, M.D., Ph.D., Assoc. Professor of Surgery in the University of Kansas. "Meat Hygiene," with special consideration of *ante-mortem* and *post-mortem* inspection of food-producing animals, 2nd edition, by Richard Edelmohr, Ph.D., of Dresden. Translated by John R. Mohler, A.M., V.M.D., and Adolph Eichhorn, D.V.S.

* * *

A REVISED and enlarged second edition of the popular series of articles, entitled "Round the Fountain," has been recently issued. As many of our readers know, this booklet consists of prose and verse collected for the most part from the *St. Bartholomew's Hospital Journal*. It will be of interest to anyone connected with the medical profession, and is sold by the Editors for the benefit of the Nurses' Home Rebuilding Fund, at the *Journal Office*, St. Bartholomew's Hospital. It certainly should, as a matter of course, be in the hands of every former "Barts." student.

* * *

A MOST useful book of reference is Low's "Hand-book of the Charities of London." It is not given to many shilling volumes to attain the highly reputable age of 77 years, for this, the oldest guide of the sort in existence, first saw the light of day in 1834. The information given as to each institution is comprehensive, as it states the object, date of foundation, office, income, expenditure, invested funds, bankers, treasurers and secretaries of over 1,200 charities. The unceasing volume of philanthropy connoted in this record bears a remarkable testimony to the philanthropy of our fellow-countrymen. This useful little work is now in the hands of the well-known firm, Messrs. Charles H. Sell, of Leighton House, Fleet Street, London, E.C.

* * *

THE following new editions are announced:—By Messrs. Longmans: Vols. I., II., III., in the eleventh edition of Quain's "Anatomy," and Vols. I., II. of Cheyne and Burghard's "Surgical Treatment." By Mr. Lewis: Carter's "Elements of Practical Medicine," tenth edition. By Messrs. Macmillan: The second edition of "A New System of Medicine," by many writers, and a "Text-Book of Pathology" by Dr. Geo.

Adami and Dr. J. McCrae. By Messrs. Lippincott: The tenth edition of White and Martin's "Genito-Urinary Surgery and Venereal Diseases." By Messrs. Appletons: The eighth edition of Osler's "Practice of Medicine," and by Messrs. Smith, Elder and Co., a new edition of Marshall and Hurst's "Junior Course of Practical Zoology."

* * *

THE study of diseases of the Tropics has become such an important feature in medical education that we are now promised a new fortnightly journal, entitled the "Tropical Diseases Bulletin," under the general editorship of the Director of the Tropical Diseases Bureau, Imperial Institute, London, A. G. Bagshawe, M.B., D.P.H., Cantab., F.L.S. The first number will appear in November, and will be published by Messrs. Bailliere, Tindall and Cox, at an annual subscription of one guinea. The Tropical and Sub-Tropical Diseases of Man will be grouped in sections, which will be in charge of the following sectional editors:—Fleet-Surgeon P. W. Bassett-Smith, C.B., Lt.-Col. C. Birt, R.A.M.C., Dr. W. Carnegie Brown, Professor George Dean, Dr. H. B. Fantham, Dr. Edward Hindle, Dr. R. T. Leiper, Dr. David Thomson, Dr. C. M. Wenyon. Groups will be taken also by the Director and Assistant Director, and each number will consist of about fifty pages.

NEW PREPARATIONS.

"HYDROQUININE HYDROCHLORIC" (ZIMMER).

A NEW quinine preparation has been placed on the market by Messrs. Zimmer and Co., of Frankfurt. A specimen has been sent us, and from a careful examination we are pleased to say that this new compound would appear to have a good future before it. The formula is dihydroquinine hydrochloric, which differs from quinine in that it contains two hydrogen atoms more than the latter. Its composition is as follows:— $C_{20}H_{26}N_2O_9 \cdot HCl + H_2O$. Hydroquinine occurs in small quantities in the cinchona barks and is very similar to quinine as regards its properties so that it can only with great difficulty be separated from quinine. We have now succeeded in preparing this alkaloid synthetically from quinine, and there is nothing now to impede its therapeutical employment. The difference between quinine and hydroquinine in the treatment of trypanosome infection is said to be striking. Of eleven animals treated with quinine nine succumbed to the infection, whilst there was only one death among the same number of animals treated with hydroquinine. These and analogous experiments show that, all things being equal, hydroquinine is superior to quinine in the protection against the infection. Doses of hydroquinine hydrochloric, on the other hand, injected 1—3 times on consecutive days, result in almost all cases in the complete disappearance of trypanosomes from the circulatory system.

Free trial quantities of hydroquinine hydrochloric as such, or in solution (ampls of $7\frac{1}{2}$ grains, ready for injections) are at the disposal of medical men.

MEDICAL NEWS IN BRIEF.

Death under an Anæsthetic.

THE death under an anæsthetic of Henry Adolf Nidden, aged 14, was the subject of a recent inquest at South Shields by Coroner Graham.

John Petersen, said the deceased, his nephew, complained of pain in the abdomen on Saturday, August 31st, and on Dr. Crichton's advice he was removed to the Wellington Terrace Nursing Home for an operation, which was performed on Saturday last.

Dr. Marks stated that the operation had been in progress four or five minutes when the boy's respiration

suddenly ceased. Death was due to heart failure. He examined the boy before operation, and considered that he was in a fit state to undergo it. The operation was necessary. He had administered chloroform in hundreds of cases, he said, in reply to the Coroner, and this was his first fatal case.

The jury found that death was due to heart failure while the patient was under the influence of chloroform properly administered for the purpose of a necessary surgical operation.

Death under Anæsthetic—Strange Hoxton Case.

At the City Coroner's Court on the 11th inst., Dr. Waldo inquired into the death of Ruth Gertrude Gibbs, æt. 24, which took place at St. Bartholomew's Hospital while undergoing an operation.

Deceased was received into the Hoxton Infirmary on April 10th last suffering from wounds to the throat and right hand. After treatment she was able to leave the infirmary on May 14th, and went to reside at a friend's house. She returned to work as a box-maker, but not having regained the full use of her right arm she, about six weeks ago, consulted a doctor at St. Bartholomew's Hospital, and was advised to undergo an operation. She was admitted on August 28th.

Deceased's husband, William John Gibbs, a packer and ex-soldier, was arrested in connection with the injuries received by the woman in April, and was charged with attempted murder. He was tried at the Old Bailey, and was convicted of the lesser charge of feloniously wounding, being sentenced to four years' penal servitude. The husband, who is undergoing his sentence at Portland Prison, attended the inquest under escort, and was permitted to sit beside his father at the solicitors' table.

Police-constable John Fever stated that he found the deceased lying on the ground and Gibbs bending over her. The woman was bleeding from the neck. He asked Gibbs what he knew about it, and he said, "I done it, governor. It is all her own fault. She has left me. I promised it to her, and now she has got it." Gibbs then produced a razor and said, "I have done it with this."

The House-Surgeon of the Hoxton Infirmary stated that the deceased's wounds healed and she was discharged in good health. He did not find any nerve injured, but the nerve running through the muscles must have been severed, although he did not detect it.

Dr. Grange, House Surgeon of St. Bartholomew's Hospital, stated that it was found that there was an injury to a nerve, and it was suggested there should be an operation for joining together the ends of the nerve. Deceased collapsed while the operation was being performed. She had said that she had had rheumatic fever three years ago, and there was disease of a valve of the heart, which might have been the result of rheumatism.

Dr. Spilsbury, pathologist at St. Mary's Hospital, said the nerve of the right side of the neck was severed, the effect of which was to paralyse and produce a wasting of the muscles supplied by the nerve. The immediate cause of death was heart failure due to disease of the heart muscle. He believed if the anæsthetic had not been given death would not have occurred, but the operation was a long and painful one, and the anæsthetic was necessary.

In answer to a jurymen, Dr. Spilsbury said if the deceased had not had the wound in the throat the operation would not have been necessary.

Dr. Gill, who administered the anæsthetic stated that he was informed that there was disease of the heart, and considering that the operation was not one for a junior to undertake, he undertook to administer the anæsthetic himself. He chose chloroform, as the operation was one of delicacy. A normal quantity was used, and the usual system was followed. He considered that death was natural, and that the chloroform did not hasten death. The woman was liable to die at any moment, especially in stages of emotion. Death, in his opinion, was due to fatty degeneration of the heart.

In regard to the proportion of deaths under anæsthetics, Dr. Gill said that it worked out at about one in 9,000 or 10,000 for St. Bartholomew's Hospital.

Gibbs asked witness if he thought the operation was justified when it was known that the deceased's heart was weak, and Dr. Gill pointed out that such condition was very common, and every precaution was taken.

Dr. Grange, recalled, said that he was of opinion that death was due to heart failure from an exciting cause, and that the exciting cause was the anæsthetic. He, therefore, agreed with Dr. Spilsbury, and considered that the death was unnatural.

The coroner said the case was a very peculiar one. He had never in his experience known a case like it. It was for the jury to say whether the man Gibbs was to blame criminally for the woman's death. The case was a very difficult one. The operation was not a means for the preservation of life following the injury. If the woman had not had the operation there was a possibility that she might have lived. If the jury decided to set aside the question of murder, and considered that death was unnatural, they might bring in a verdict of misadventure.

The jury retired to consider their verdict, which they gave as "Death by misadventure."

St. Mary's Hospital Medical School, Paddington.

The opening of the Winter Session will take place on Tuesday, October 1st, at 3.30 p.m., when the prizes and awards for 1911-12 will be presented by the Lord Mayor of London.

The Annual Dinner of Past and Present Students will be held on Wednesday, October 2nd, at the Grand Hall, Princes' Restaurant, at 7 p.m. The chair will be occupied by Dr. W. J. Gow, Senior Obstetric Surgeon to the Hospital.

The Royal Life Saving Society.

DURING the first half-year of 1911 the Royal Life Saving Society granted 3,799 awards, and during the first half-year of 1912 these figures were increased to 5,506. For the life-saving competitions a large number of entries have been received, 108 teams, representing nearly 500 individual competitors, having been registered for various tests. The classes of instruction in the Navy and the Army at home and on foreign stations show an increase.

Closing of an Asylum.

It is reported that the managers of the Poplar and Stepney Sick Asylum have decided to give notice to terminate the lease of their Blackwall Branch Asylum, and the place will be closed. The branch asylum was originally opened for the reception of children, but the Metropolitan Asylums Board having since taken charge of children there is no longer need for the place, which has been used for adult patients. It is stated that the Stepney Guardians will save £1,000 a year by the closing of the Blackwall Asylum and that the Poplar Guardians will save an amount equal to a penny rate.

New Hospital for Women in London.

BESIDE the hospitals for women to which we referred in our last issue, we understand it is now proposed to erect a new hospital for women in South London on a site of three acres, which has already been obtained with a frontage on Clapham Common. A committee has already been elected, and the building will contain an in-patient department with general and private wards, the latter being intended for women of small means who cannot afford to go to a nursing home. Women doctors will be on the honorary staff, and there will also be a well-staffed out-patient department with a woman inquiry officer.

The scheme is being supported by Mrs. Garrett Anderson, M.D., Lady Robert Cecil, Lady Cowdray, Sir Bryan Donkin, Sir James Goodhart, Lady Roberts, Mrs. Scharlieb, M.D., the Bishop of Southwark, and the Bishop of Winchester.

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS.

FOR ONE INSERTION.—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.; The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8 Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

MALA FIDES.—The book is out of print.

MATRON.—It has been stated that a newly-laid egg, which is sterile can be kept fresh in a refrigerator for ten months.

DR. H. J. A. C. (Jersey).—We have been unable to trace the source of the matter referred to.

MOTHER SEIGEL, LIMITED.

We understand that the directors of that American importation, "Mother Seigel's Syrup," for which the astute discoverer (?) got nearly £1,000,000 from British investors, are about to propose to the unfortunate shareholders that the £1 shares be reduced to two shillings, as they find it impossible to pay dividends out of the profits of this huge capital.

UNITED SERVICES CLUB.—The individual about whom you inquire should be left severely alone. He has gone under various aliases, and was at one time connected with that notorious scoundrel Dr. Crippen. We greatly regret that the daily newspapers should accept the ill-gotten money of such a dangerous quack, while pretending to safeguard the interests of the community.

L. S. A. (Lewisham).—All cases of infectious diseases in and around London, are undertaken by the Metropolitan Asylums Board and the London Fever Hospital.

IMPERIAL CANCER RESEARCH FUND.

A CORRESPONDENT writes to us as follows:—

"It is to be hoped that the Committee of the Fund will follow the example of the Sleeping Sickness Bureau and set to work on the compilation of a complete bibliography of Cancer and the collection and formation of a library containing every work, paper, lecture, etc., which has been published relating to the subject. We believe a suggestion has already been made to Dr. Bashford on this matter and he would be well advised to give it full consideration."

M.B.O.S. (Reading).—Both the Buxton Thermal and Chalybeate water can be obtained direct from the Municipal Springs. The Radiozone bath salts largely used in the Buxton treatment can also be purchased for the home treatment of patients. Fuller particulars can be obtained by writing to the Manager of the Mineral Springs, Buxton.

GERMINATING APPLE PIP IN APPENDIX.

A London evening journal reports that in the course of an operation for appendicitis on a young man at Haverfordwest, Pembrokeshire, the presence was revealed of an apple pip which had not only set up inflammation, but had actually begun to germinate.

Appointments.

- BROWN, W. G. S., M.R.C.S., L.R.C.P., Resident Assistant Medical Officer of the Prescott Union Workhouse.
 COLLINS, E. A., M.R.C.S., L.R.C.P., District Medical Officer of the Blything Union.
 DOWLET, T. P. B.A., M.B., B.Ch., B.A.O. Durh., Certifying Factory Surgeon for the Lisbellan District, co. Fermanagh.
 FRAZER, A., M.B. Edin., M.B., C.M., Certifying Factory Surgeon for the Caistor District, co. Lincoln.
 HOBSON, W. H., M.B., M.R.C.S., L.R.C.P., District Medical Officer of the Hyde Union.
 KEIR, I. C., M.D. Edin., M.B., Ch.B., D.P.H., Medical Officer of the Trowbridge and Melksham Union Workhouse.

- RADCLIFFE, A. H., M.B., Ch.B. Vict., D.P.H., Certifying Factory Surgeon for the Gasford District, co. York.
 SHARP, Miss A. C., M.B., Ch.B. Edin., Assistant Medical Officer of the Plymouth Union Workhouse.
 STEWART, T. L. G., M.B., Ch.B. Glasg., Assistant Medical Officer of the Liverpool Union Brownlow Hill Workhouse.
 TAYLOR, J. M., M.B., District Medical Officer of the Thorne Union.
 THOMPSON, S. W., L.S.A., M.R.C.S., District Medical Officer of the Greenwich Union.
 VINCENT, W. H., L.M.S.S.A., House-Surgeon to the Evelina Hospital for Children, Southwark, S.E.

Vacancies.

- Royal Victoria Eye and Ear Hospital.—Two House Surgeons. Salary £40 per annum with board. Applications to the Hon. Secretary, Adelaide Road. (See advert).
 Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—Abbeyleafe (co. Limerick), Bellanagh (co. Cavan), Castlegregory (co. Kerry), Corris (Merioneth), Dingle (co. Kerry), Ongar (Essex), Rathvilly (co. Carlow).
 Buenos Ayres British Hospital.—Assistant Resident Medical Officer. Salary £200, rising £25 annually. First-class passage paid. Board and rooms in Hospital provided. Applications to Dr. Colbourne, Llanfair, Beckenham, Kent. (See advert).
 King Edward VII. Sanatorium, Midhurst, Sussex.—Junior Assistant Medical Officer. Salary £150 per annum, with board, lodging and attendance. Applications to the Honorary Secretary, 19 Devonshire Street, Portland Place, London, W.
 Southwark Union, London.—Third Assistant Medical Officer. Salary £120 per annum, with board, lodging and washing. Applications to Sydney Wood, Clerk, Union Offices, Ufford Street, Blackfriars Road, S.E.
 Lincoln County Hospital.—Junior House Surgeon. Salary £100 per annum, with board, residence and washing. Applications to the Secretary-Superintendent.
 Kidderminster Infirmary and Children's Hospital.—House Surgeon. Salary £100 per annum and board. Applications to the Secretary.
 Bolton Infirmary and Dispensary.—Senior Assistant House Surgeon. Salary £100 per annum, with board, apartments and attendance. Applications to W. W. Cannon, Esq., Hon. Secretary, The Infirmary, Bolton.
 Parish of Leicester.—Poor-law Infirmary. Second Resident Assistant Medical Officer. Salary £130 per annum, with rations, furnished apartments and washing. Applications to Herbert Mansfield, Clerk to the Guardians, Poor-law Offices, County Borough of Southampton.—Assistant Medical Officer of Health. Salary £200 per annum, with residence, board and washing. Applications to the Town Clerk, Municipal Offices, Southampton.
 Coton Hill Lunatic Hospital, Stafford.—Assistant Medical Officer. Salary £150 per annum, with residence, board and laundry. Applications to the Medical Superintendent.

Births.

- CORRY.—On September 5th, at Liss, Hants, the wife of Harry Barrett Corry, B.A. Cantab., M.R.C.S., L.R.C.P., twin daughters.
 CREAM.—On September 13th, at 13 Queen Street, Mayfair, London, the wife of Thomas J. Cream, V.C., F.R.C.S., of a daughter.
 WHITE.—On September 4th, at Landour, N. India, the wife of Captain M. F. White, I.M.S., of a son.

Marriages.

- BACON—BAILEY.—On September 9th, at St. Peter's Church, Hong-kong, the Rev. John Lionel Bacon, L.Th. Dur., son of the late William Bacon, of Hadleigh, Suffolk, and of Mrs. Bacon, Rosemont Road, Acton, W., to Charlotte Bailey, M.B., Ch.B. Birm., eldest daughter of Thomas Henry Bailey, M.Inst.C.E., of Portland Road, Edgbaston (C.M.S. Missionary at Kueilin, Kwangsi). (By cable).
 BAINES—RANSOME.—On September 11th, at the Mission Church, Lytton, British Columbia, Mark Blakiston Baines, M.B. Oxon., son of Mr. and Mrs. Henry Baines, of Oxford, to Violet Grace, only daughter of Mr. and Mrs. Stafford Ransome, of 15 Redcliffe Square, South Kensington.
 LEES—SLATER.—On September 11th, at St. Paul's Church, Avenue Road, William Donald, eldest son of David B. Lees, M.D., F.R.C.P., of 22 Weymouth Street, W., to Ida Lillian, youngest daughter of John Slater, of 11 St. John's Wood Park, N.W.

Deaths.

- BARRY.—On September 9th, at his residence, Whitehead Road, Aston, Birmingham, Hart L. A. Barry, L.R.C.P. and L.R.C.S.I., aged 32.
 SPITZLY.—On September 11th, at 1 Douglas Road, John H. Spitzly, M.R.C.S., L.R.C.P.
 THOMPSON.—On September 2nd, 1912, at Trinidad, of black-water fever, Arthur W. D. Thomson, Colonial Medical Service, of Belle Garden, Tobago, B.W.I., second son of the late Deputy Inspector-General James Thomson, R.N., in his 41st year.
 THOMPSON.—On September 10th, at 13 Cheyne Gardens, S.W., Reginald Edward Thompson, M.D., aged 78.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX."

VOL. CXLV.

WEDNESDAY, SEPTEMBER 25, 1912.

No. 13.

NOTES AND COMMENTS.

The Forcible Feeding of Suffragette Prisoners. MR. BERNARD SHAW has risen to the opportunity for catching the ear of the public afforded him by the Suffragette outcry against forcible feeding. It is at times hard to analyse the buffoonery of the talented dramatist, but it seems fairly clear on this occasion that he upholds the action of the State in feeding perforce prisoners committed for such a felonious action as the attempted setting on fire of a theatre. If such persons are to be set free because they refuse their food then a similar privilege must be extended to burglars, forgers, murderers, and other criminals of every degree. Mr. Shaw apparently disapproves of all punishment, but unfortunately we cannot deal here with that tempting side issue. He also thinks that every imprisoned woman should be allowed to starve herself to death if she so wills. It does not appear that his great brain has ever considered the mental responsibility of women who refuse food under the peculiar circumstances. A woman who smashes a shop window, or sets a theatre on fire, because she objects to what is, in her opinion, a defective constitutional law, and when imprisoned for her offence against society refuses food as a further protest is hardly to be considered sane. At any rate, the refusal of food is a common and familiar act in lunatic asylums. Recently a small committee of individuals well known in the medical world have drawn up a report upon the results of forcible feeding. They might, with equal force and with much more literary effect, have dealt with the sufferings inflicted upon the inmates of asylums by the enforcing of similar measures. It seems clear enough that any authority which assumes the responsibility of shutting persons up in custody must keep them alive and look after their safety as far as possible. This applies to recognised and established lunatics as well as to Suffragettes and other sorts of criminals. There can be no special treatment meted out to Suffragette window breakers.

Forcible Bathing! THE medical manifesto to which allusion has been made is difficult to follow. If it were part of an inquiry conducted into the physical effects of prison treatment generally by an impartial medical board the report would command our admiration and respect. As a piece of special pleading, however, put forward in favour of a small class of criminal offenders it is more likely to provoke ridicule than sympathy. In the *Lancet* of September 14th the incident is treated with Rabelaisian humour by Dr. Charles Mercier.

His communication takes the form of a "Preliminary Report on the Forcible Bathing of Prisoners." He says that having approached the subject without the slightest bias in favour of the prisoners, or against the prisoners, he has elicited a series of facts wherewith he is enabled to give the lie direct to the assertion that the forcible bathing of prisoners is neither dangerous nor painful. The impartial method of investigation was by examining prisoners on their release and by leading questions addressed to the physicians who have attended them since that event. The facts adduced in this report merit the careful attention of all members of the community concerned in the administration of justice. "One prisoner," so the document runs, "I examined (V.Z.), a strong man of fine physique, was so seriously enfeebled by having one bath that he had to be removed to hospital some time afterwards, having in the meantime broken his leg, an occurrence which he attributes to the weakening effects of the bath; and he is but typical of a considerable number." The very nature of the regulation, as shown by the investigator, defeats its own purpose, in the following remarkable passage:—"According to the prison authorities, forcible bathing was instituted to keep the prisoners clean, for which, however, they have never dirty struck. But in the majority of cases it has had precisely the opposite effect, for it is found that dirt adheres far more readily to the fresh surface exposed by the action of the bath than to the inveterate dirt of years."

The Anguish of the Tub. THE official theory that there is no danger in the bath is not borne out upon investigation, as shown by the following illustration. "B. S., a skilled chimney sweep, never resisted the operation. At Easter he had a bath once a week for three days. The anguish he experienced surpassed that of any wash he had had in previous years, and he completely lost his power of recognising even the most familiar objects. He did not even recognise his own face when he looked in the glass. This also was a type of many similar cases." The description of the physical injuries inflicted upon prisoners, if even remotely founded on fact, should arouse a storm of popular indignation. We are told that "during the struggle before bathing the prisoners were flung out of window, tossed over the roof, tied up in knots, jumped upon, and eviscerated. As might be supposed, severe bruises were thus inflicted." In another place we are told, "Though medical officers were informed in several cases that the prisoner was subject to nasal catarrh, no examination was made. The prisoners were usually flung into the bath and held there while water was flung over

them. The intense pain so produced often forced uncontrollable oaths from the prisoners. In most cases headache, backache, earache, and belly-ache—I mean severe gastric pains—as well as hydrophobia, which lasted through the forcible bathing, preventing sleep." This important document gives much additional information as to the effects of forcible bathing on the circulatory and nervous systems, and so on. Readers interested in the subject should consult the original document, which most certainly should be in the possession of Ministers who may be called upon to answer questions in the House upon the treatment of prison inmates. Dr. Mercier may be congratulated upon having made a solid contribution to the literature of a delicate and difficult socio-legal problem, and at the same time of having added to the gaiety of a serious and sober-minded profession.

The Motor Traffic Danger.

THE danger to life and limb arising from motor traffic in town and country has at length reached breaking strain. The average chauffeur seems to think that having sounded his horn he is entitled to run over any obstinate person who may remain in his path. Last week a costermonger stepped into the road to pick up another man's cap. He was run over by a motor bus, and the evidence at the inquest appeared to show that the driver made no attempt to stop, although deceased ran several yards in front of the omnibus. Under such circumstances a charge of criminal recklessness in driving should surely come into consideration. Coroners' juries and magistrates are loth to bring in a verdict blaming the chauffeur, and we note that a South London medical man, stimulated by his experiences of motor disaster, has suggested the foundation of a public defence fund for the metropolis, with a view to the securing an exhaustive investigation into every fatal case of the kind. The statement, publicly advanced and capable of ready proof or disproof, that per vehicle each motor omnibus in London kills five or six times as many persons as a horse omnibus seems startling enough to awaken the slowest commercial conscience. Provincial towns that rule their own house appear to be able to control the evil. In London, however, the matter is in the hands of the police. In a former issue we suggested that the Chief Commissioner should have a map constructed localising motor deaths by means of pins with variously coloured heads, say, red for private motors, blue for trams, yellow for omnibuses, and so on. When Parliament meets it may be hoped that some member may ask for a return of such deaths, and at the same time seek for some explanation as to why the police have allowed this particular peril to attain such dimensions in London.

What of the Police and the Home Office?

As a matter of fact the remedy for this grievous danger which stalks the streets of London by day and by night is in the hands of the police. The causes of the avoidable margin of deaths are few and simple. Excessive speed, immunity of drivers, excessive number of vehicles, want of proper investigation of accidents and deaths. As to speed there are official regulations of model type in existence, and these could be applied forthwith, if so wished by the authorities. They provide for the use by every vehicle of a device whereby a continuous alarm is sounded if the vehicle exceeds a given rate of speed. So that there need be no further dispute as to speed. Place such an indicator on every motor

vehicle and it becomes its own infallible witness. The police, again, should be legally represented at every inquest, and the licence of every chauffeur implicated in a serious or fatal accident be seriously imperilled, and in case of several such occurrences be permanently revoked. It would be interesting to learn the individual record of deaths attributable to individual drivers of public motor vehicles. In view of the failure of local authorities throughout the Kingdom to deal with the dangers of motor traffic, in our opinion a Royal Commission or a Select Committee should be appointed at once on the reassembling of Parliament to collect authoritative information on the whole question. What about the Home Office responsibility in the matter?

The Eighth London Medical Exhibition.

WE have pleasure in drawing the attention of our readers to the eighth London Medical Exhibition, which is to be held at the Royal Horticultural Hall, Vincent Square, Westminster, in the week beginning the 30th September and ending on the 4th October. Tickets of invitation are sent to every medical man residing within a 50-mile radius of the hall, but those not thus included can obtain cards on application to the Secretary, 194-200, Bishopsgate, London, E.C. Of all organisations of the kind this appears to be easily the first in attractiveness to medical men. The reason for this preference is not far to seek; it will be found in the admirable way in which the arrangements are carried out. The imposition of an admission fee of five shillings to all but members of the medical profession practically shuts out the general public. As a result medical visitors are enabled to make the round of the exhibits in comfort, a privilege that was certainly conspicuous by its absence in the case of exhibitions of the sort attended by the outside public. Another attraction so far as the profession is concerned lies in the variety and comprehensiveness of exhibits bearing on every phase of medical practice. Here, at a glance, the practitioner, whatever his special wants may be, can inform himself of the latest mechanical and scientific developments placed at his disposal by the combination of commercial enterprise with advanced medical science.

LEADING ARTICLES.

THE REGULATIONS FOR MEDICAL BENEFITS UNDER THE INSURANCE ACT.

AFTER what must have appeared to many of our readers a long and wearisome delay, it is announced upon what appears to be good authority that the State Insurance Committee of the British Medical Association is now in possession of the final terms of settlement proffered by the Government to the medical profession. The announcement is made in the *Times* of September 23, 1912, with an air of authority that, coming from such a source, must be accepted as of good warranty. The regulations, we understand, have not been settled in final form, so far as wording goes, but will shortly be redrafted. They were sent by the Insurance Commissioners to the State Sicknes Committee as an act of courtesy, and not in order to invite their opinion as to suggested modifications, for as negotiations have been broken off between the British Medical Association and the Government the former have no *locus standi* in the matter. To this-

is added the statement that it is possible the Commissioners may accept one or two minor points which the doctors may urge.

The Regulations, says the *Times*, are said by some experts to give ground for hopes of a settlement. The question of remuneration for medical attendance is left to the local health committees, who have the option of arranging payment on any of the four following bases:—

- (1) Capitation only.
- (2) A small capitation fee with some payment for special services.
- (3) Payment for special services with a small capitation fee.
- (4) Payment by attendance only.

The difference between (2) and (3), it is explained, is that in the former the capitation fee, though small, is the main basis of the proposal; in the other the main basis is the payment for special services. It is anticipated that the State Sickness Committee will now draft a report to be sent to all the members of the British Medical Association. In the meantime the Committee has, it is stated on authority, received assurances that at the next Cabinet meeting, the one which will immediately precede the opening of Parliament, Mr. Lloyd George will make a statement on the situation. He is expected to point out that the reserve sums under his original proposals which had been set aside to meet unexpected outlays have been swallowed up by acts of generosity adopted by the House of Commons for the benefit of the contributors. These, therefore, could not be applied to meeting the claims of the doctors, claims which to a large extent he had always recognised as being substantially just, claims which he had always admitted would have to be partially met. He will therefore suggest that when Parliament reassembles it should be asked to vote a special percentage out of State funds towards the Insurance Fund. At the present time it is not known what this sum will be, but it may be 2 per cent. It is certainly not likely that Mr. Lloyd George will propose that a specific amount of money should be voted, or that the State will be asked to increase its contribution towards each case of insurance. There is no doubt that the Cabinet will agree to this course. Our readers will please note that the foregoing important statements are quoted from the *Times*. The next step on behalf of the British Medical Association will doubtless be to circularise and ascertain the views of the medical profession as a whole. Later, the final decision will probably be arrived at by the meeting of representatives to be held in November next. On the whole, it may be said that the Regulations, if the *Times* view be correct and well-informed, have somewhat lightened the situation. At the same time the medical profession will do well to persevere in the organisation of a public medical service for reasons that have been fully discussed in our columns on former occasions.

At the moment of going to Press we find that the *Times* has published what amounts to a direct contradiction of the foregoing statements, so that our readers will have to accept any rumours that may be circulated for the next few days with much caution.

THE POSITION OF DENTISTRY.—I.

IF the secret history of medical law reform be one day written, the part played by the MEDICAL PRESS may be perhaps revealed. The difficulties of getting at the general public through a medical paper are insuperable, but there are available means of bringing medical questions of national interest forcibly to the notice of statesmen, Members of Parliament and public men; and these have been continuously employed in recent times. These efforts helped largely in the promotion of the Parliamentary inquiry into the quack medicine trade. The evidence gathered by the Select Committee will at least greatly strengthen the demand for a similar inquiry into the whole position of medical law. That inquiry must, of course, include the Dentists Act. We propose to bring this question to the front; and, seeing that the story of the rise of dentistry is not known to many medical men or even to dentists of the younger generation, it may be well to start with a brief account of the genesis of the Dentists Act. Although there had been for many years a number of qualified men engaged in dentistry, a dental profession cannot be said to have existed in this country prior to the year 1858. In that year the Royal College of Surgeons obtained through the new Medical Act powers for the creation of a Licence in Dental Surgery. The need for measures to improve the status of dental practitioners had been recognised long before, and much had been done to promote them. The final success was in great part due to the personal position of leading dentists. Some of these were Fellows of the Royal Society; others held degrees in medicine or surgery; many of them were known as serious workers in science. The Medical Act of 1858 gave no power to compel practitioners of dentistry to qualify. It remained still possible for anyone, devoid of professional education, to practise, and use, with impunity, titles implying the possession of a valid diploma. It was left to the option of pupils whether they would obtain a voucher of their professional competency, and between the years 1858 and 1878, a considerable number of students went through the educational course and became qualified. A considerable minority became fully qualified surgeons; others took degrees in arts or science. The existence from the first of a large number of dentists holding high academic degrees, besides a dental diploma, has tended to bind the speciality closely to the medical profession. Diseases of the teeth are often enough alone to make life as wretched as it can be made by any form of physical suffering. In a not inconsiderable proportion of cases dental diseases form the cause of morbid conditions of the general system. In another class of cases affections of the teeth are in causal relation with grave surgical diseases of the mouth and jaws. To treat maladies other than those strictly dental falls beyond his province, but if the dentist be a mere mechanic he must often ignore conditions the early recognition of which would have averted serious

or disastrous results. Of this fact illustrations can be seen among the patients of every hospital—among the poor and ignorant, whose cases are so often neglected until too late. Operative dentistry is a highly technical system of surgical handicraft, calling for a high degree of manual training. In what seem purely mechanical processes, scientific thought has been brought to bear, and the operator lacking knowledge must inflict unnecessary pain and injury. This equally applies to what looks at first sight the most purely mechanical of all the operations of dentistry—the construction of artificial teeth. The operation of extracting teeth calls for diagnostic skill. Toothache is very commonly neuralgic in character, and when of local origin, the pain arising from one tooth is often reflected on to another. An operator who indiscriminately extracts teeth which the patient points to as the source of suffering must, in a large proportion of cases, draw a wrong tooth, and often sacrifice a sound one. In the great majority of cases needing artificial teeth, diseased teeth are present, and unless the patient is to be condemned to constant pain and discomfort, and exposed to the perhaps mortal dangers of septic infection, these must be brought into a healthy state before artificial teeth are inserted. The calamitous results of septic mouth as displayed in the victims of dental quackery were graphically described by a "Hospital Dentist" in our Correspondence columns last week. Considerations such as the foregoing gave impulse to the movements for dental reform, and induced medical authorities and Parliament to give to dentistry the professional status it had been shown to deserve. It was, however, not until 1878 that legislative sanction was given to dental reform. By the Dentists Act of that year dentistry was placed under the direction and control of the General Medical Council. The substance of the penal section of the Act is as follows: "From and after August 1st, 1879, a person shall not be entitled to use the title of 'dentist,' or of 'dental practitioner,' or any title or description implying that he is registered under this Act, or that he is a person specially qualified to practise dentistry, unless he is registered under this Act." Any person who, after August 1st, 1879, not being registered under this Act, takes or uses any such aforesaid title or description shall be liable on summary conviction to a fine not exceeding twenty pounds." In order that no hardship should be inflicted, it was provided that every person who at the passing of the Act was in the *bonâ fide* practice of dentistry should be entitled to registration. On completion of the first Register, it was found that 5,289 names had been entered of such persons, and of these only about 10 per cent.—actually 533—had produced any evidence of dental education. The story of the gradual encroachment of the unqualified practitioner and finally of the virtual nullification of the protective clauses of the Dentists Act by a judgment

of the House of Lords, has been from year to year told in these pages.

We propose to discuss the present position of the dental profession, and to indicate remedies for existing abuses, in a series of articles. In this crusade the help of qualified dentists is cordially invited, not merely on the ground of their own interest, but also of the whole profession to which they are allied, and of the public who are suffering most injury through the present state of things.

CURRENT TOPICS.

Tuberculosis and the Insurance Act.

To the ill-informed pseudo-humanitarian, and to the simple sentimentalist, the question of the treatment appears more important than that of the prevention of tuberculosis. Cases in the incipient or advanced stages of the malady excite the utmost pity, and the demand follows that every means which medical science and art are able to furnish shall be employed in the endeavour to cure or prolong the lives of sufferers. If the question be viewed in the dry light of science it is none the less evident that the same amount of energy devoted to prevention would more speedily put an end to a far greater mass of human suffering and misery; and it seems clear that if the resources of the State do not suffice to deal with the two things at the same time it would be better to concentrate effort on the problem of prophylaxis. In this the housing question comes first. The slum and the slum-dwelling form the hot-beds of tuberculosis. Next, perhaps, comes the question of infection through milk and tuberculous flesh-foods. The enormous cost of dealing effectively with these sources of the disease has been recently exposed in these columns; but it is hardly doubtful whether it would not, in every sense of the word, pay better to devote the money proposed to be expended on sanatoria to the stamping out of bovine tuberculosis, and putting an end to the traffic in tuberculous meat. These seem evidently the opinions of Dr. Crocker, the medical officer to the Richmond Town Council. After an examination of the Surrey County Council scheme for dealing with tuberculosis, Dr. Crocker states that Richmond can provide the same facilities at half the cost. The county scheme, he says, would result in overlapping of duty, division of responsibility, and friction in administration. The chief object is the prevention of tuberculosis; and the prevention of overcrowding, house to house inspection of small property, and improvement in sanitary surroundings will, he urges, be of far greater advantage than "tinkering with the individual by sanatorium or dispensary treatment" after he has contracted the disease. Guided by this advice, the council have decided that a *prima facie* case has been made out for an independent local scheme, and have resolved to ask the Local Government Board to defer passing the county scheme in so far as it relates to Richmond. It is to be hoped that many other urban authorities throughout the country will follow the example of the Richmond Council.

The Prevention of Consumption.

SINCE the foregoing paragraph was written, there has been published an appeal, signed by Lord Balfour of Burleigh, Mr. George Harwood, M.P., and Mr. J. J. Perkins, for £10,000 in aid of the National Association for the Prevention of Consumption. The appeal emphasises the truth we have always insisted upon—"it is good to cure consumption, but it is infinitely better to prevent it." The appeal rightly insists that prevention must lie

in the hands of the people themselves, but the nation requires to be taught how to defend itself. It may be said that the Government has taken over the control of consumption, and that there is, therefore, no need for outside help. But this is far from true. The National Insurance Act, so far from diminishing the need for voluntary effort, has actually opened up a new field for work, and the people need to be aroused to take advantage of the great openings to be provided under it. The appeal urges that the record of the Association is the best proof of its fitness for this task. Though it has provided more than 600 beds for sanatorium treatment, this has been incidental to its main work, which has always laid in the domain of education. The plan which has proved most effective is by means of (1) travelling exhibitions, consisting of diagrams, models, and pictures, giving a complete illustration of the causes of tuberculosis and the prevention and treatment of the disease; (2) caravans of a similar nature and popular lectures; (3) the distribution of literature. The exhibitions are held in the larger centres of population, while the caravans tour the country districts. Everywhere the people are eager to learn. The opening exhibition in Whitechapel attracted in 17 days 70,000 of the people who most require the instruction offered. It has since visited 50 boroughs, and everywhere a like anxiety to learn has been shown. The total attendances have reached nearly one million.

Independence Day of 1912.

ALMOST since the first celebration of the declaration of independence of the United States of America, the 4th of July has been the notorious occasion for wholesale self-destruction and mutilation all through America. Nearly as many inhabitants of the States have perished in the celebration of independence as in its acquirement. It was, perhaps, the inevitable result of the reaction against despotism that the free citizens should ignore any regulations passed by their lawgivers, to ensure public safety. As lately as 1903, 466 persons were killed on the 4th of July, and of these 406 were the victims of tetanus. This year 41 persons lost their lives, including 6 deaths from tetanus. The causes of this smaller death-roll are both general and particular. The American citizen is gradually becoming more law-abiding and considerably less of a child, but much improvement is necessary still, for 41 senseless deaths and 947 people rendered blind or otherwise mutilated by explosives is too large a toll to pay for the questionable privilege of excessive individual independence. The more particular reason for the diminished number of tetanus cases lies in the adoption of more rational methods of wound treatment. Since practitioners have become careful to treat all wounds inflicted by explosives by the open method, the death-rate from tetanus has steadily diminished. Many hospitals use a solution of 5 per cent. carbolic with 0.5 per cent. hydrochloric acid as the immediate antiseptic for wounds, and an increasing number give routine prophylactic injections of anti-tetanic serum. As soon as rational methods of enjoyment and medical treatment are initiated, so soon does improvement begin, and that improvement is inevitably permanent.

The Relation of Athletics to the Reproductive Life of Woman.

WITH the growing popularity of athletics amongst women, there is increasing discussion in regard to the effects of active physical exercise on the birth-rate and on general feminine physique. There are those of the older school who would

have us believe that any violent sport such as hockey or tennis undertaken during the menstrual period has a serious effect on a girl's physical well-being. Others of a more modern type hold that menstruation proceeds more smoothly and naturally when there is no extraneous stress thrown on the body. Individual variations are so marked that we have absolutely no data on which to base far-reaching conclusions. As a rule we think that it is safe to allow girls to follow their own inclinations as to whether they should engage in active sport or not during the period of menstrual flow. In schools and colleges it cannot be wise to make games compulsory during this period; and if a girl obviously ignores her sexual functions for the sake of games it is the duty of the instructor to prevent her overtaxing her strength. We have abundant evidence that mental overwork about the time of puberty may be fraught with disastrous consequences, and to a lesser degree we would expect ill effects to follow physical over-exertion. With regard to parturition the results of an investigation recently published in the *American Journal of Obstetrics* show that the general condition of athletic patients during child-birth is much better than that of non-athletic individuals, and that labour itself is accomplished with few complications and with relative ease. With regard to displacements of the uterus, these can be brought about by violent exercise during menstruation, but such a cause of malposition cannot generally be definitely ascertained. The end of the matter is that moderation is good, excess evil, and compulsion iniquitous, and that we have to give our girls credit for the common-sense which only credit can give.

PERSONAL.

LIEUT. C. H. SMITH, I.M.S., has been appointed a Specialist in Advanced Operative Surgery.

DR. P. J. O'FARRELL has been appointed Assistant Physician to Temple Street Children's Hospital, Dublin.

DR. THOMAS ROBERTS, of Wrexham, has been appointed County Medical Officer of Health for Denbighshire.

DR. R. E. HARROLD, M.B., Ch.B. Ad., has been appointed Honorary Dermatologist to the Adelaide Hospital.

MR. JOHN MORLEY, Ch.M. Manch., F.R.C.S., has been appointed Honorary Surgeon to the Ancoats Hospital, Manchester.

DR. J. BELL FERGUSON, M.B., Ch.B. Edin., D.P.H. Manch., has been appointed chief Tuberculosis Medical Officer for the County and City of York.

DR. H. J. MACINTOSH, Medical Superintendent of the Western Infirmary, Glasgow, has been elected Chairman of the British Hospitals Association for the ensuing year.

DR. G. MORRISON, the Political Adviser to the President of the Chinese Republic, with Mrs. Morrison, have now left England for Peking, travelling via Berlin and Moscow.

DR. J. KING PATRICK, M.B., Ch.B., B.Sc. Glas., D.P.H. Dub., has been appointed Assistant Medical Officer of Health and Medical Officer in Charge of the Tuberculosis Dispensary for the County Borough of Leicester, *vice* Dr. J. Bell Ferguson.

DR. G. STOPFORD TAYLOR, of Liverpool, will deliver the opening address before the New London Dermatological Society on Thursday, October 10th, at 4.30 p.m., at the Western Skin Hospital, Hampstead Road, N.W., on "Some Practical Points in the Treatment of Eczema." All practitioners are cordially invited.

A CLINICAL LECTURE

ON

SYPHILIS OF THE NERVOUS SYSTEM, ILLUSTRATED BY THREE CASES.

By H. L. McKISACK, M.D., M.R.C.P.,

Physician to the Royal Victoria Hospital, Belfast.

THE effects of syphilis upon the nervous system are extremely varied, as regards both their situation and their clinical signs. We must bear in mind that there is no region of the nervous system immune to syphilitic processes, and, further, that these processes have nothing distinctive or pathognomonic in their character, whereby they may be recognised with certainty. It is only by the history, by the results of treatment, and by the presence of the Wassermann test that one perceives the specific factor in the case. The fact that so many diseases of the nervous system are hardly, or not at all, amenable to treatment, makes one welcome the evidence of syphilis in these diseases, and it is fortunate that this is not a rare occurrence; a fair proportion of diseases of the brain and spinal cord being of syphilitic origin. In many cases of syphilis of the nervous system there are grounds for a hopeful prognosis. Unfortunately, there is also a large group of nervous diseases occurring in syphilitic subjects for which the anti-syphilitic treatment is useless. These are the so-called meta-syphilitides or degenerative affections of the brain and spinal cord occurring at a later period in the syphilitic patient's life. Of these the following may be mentioned: general paralysis of the insane, locomotor ataxia, spastic paraplegia, and some forms of myelitis and dementia.

These diseases are, in many cases, but not in all, the result of syphilis, which produces such changes in the nutrition of the nervous tissues, as renders them liable to degeneration or chronic inflammation. The situation in which the diseased condition mainly occurs, accounts for the variety of disease under observation. Thus in locomotor ataxia, it is chiefly the posterior columns of the cord that are affected. In general paresis there is a widespread affection of the surface of the brain with, in many cases, lesions of the cord involving both posterior and lateral columns. If the lateral columns are chiefly attacked, syphilitic spastic paraplegia is the result. These and similar degenerative lesions cannot, as has just been stated, be regarded as syphilitic diseases of the nervous system, but as degenerative changes which occur very frequently in individuals who have previously suffered from syphilis, and the vitality of whose tissues has been injuriously affected by the poison.

Diseases of the nervous system directly the result of syphilis occur almost exclusively in the tertiary stage of the disease. In the earlier stages organic changes in the nervous system are not at all likely to occur; at an rate, not more than could be accounted for by coincidence.

It is not only in the acquired disease that nervous lesions occur; in cases of hereditary syphilis almost every variety of syphilitide may be found, with in addition various developmental abnormalities.

With regard to the region of the nervous system which may be affected, the brain and the spinal cord are most frequently the seat of syphilitic disease. The peripheral nerves, however, though rarely involved, are not entirely exempt from the

disease. Syphilis, in common with other diseases, may attack the tissues adjoining the nervous structures, which may be injured, without being themselves the seat of syphilis. Thus syphilitic tumours of the skull, or of the bones of the spinal column, may, by pressure, cause disease of the brain or cord, but cannot be regarded as syphilis of the nervous system.

(a) The commonest specific lesion in the brain and spinal cord is a form of meningitis, with which may be found some inflammation of the nerve tissues, and of the arteries. From two to ten years after the infection, inflammatory exudation of a gummy character may appear. It is specially found at the base of the brain in the neighbourhood of the chiasma, crura and pons, but may occur elsewhere in the cerebro-spinal canal. The symptoms produced by this exudate resemble closely those of a tumour, not only on the surface, but in the substance of the brain or cord. The condition thus produced may be regarded as meningitis with tumour, or inflammation of the adjacent brain or spinal cord, that is syphilitic meningo-encephalitis or myelitis, producing in some cases considerable areas of softening. In other cases the lesion may take the form of small scattered spots producing sclerosis, or, on the contrary, softening of limited areas. The result is a group of symptoms closely resembling multiple sclerosis or general paresis, with the important difference, however, that the purely syphilitic disease which we are considering is favourably influenced by anti-syphilitic treatment, while the affections just mentioned, even if they occur in a syphilitic subject, are not usually benefited by mercury or iodide of potassium.

(b) At times arteritis is the only discoverable lesion, and may give rise to no definite symptoms until the vessel becomes the seat of thrombosis, or ruptures, when the usual symptoms develop in accordance with the situation and extent of the lesion.

(c) Gummatous deposits on the cranial or spinal nerves may occasionally be found giving rise to pain, paræsthesia, anæsthesia, or paralysis. The symptoms are those of neuritis of the nerve affected, with possibly local pressure symptoms, should the gumma be of sufficient size.

(d) A fourth group of nervous disturbances of syphilitic origin comprises cases of functional disorder of the nervous system, without physical signs of organic lesion. In these cases neurasthenia, insomnia, headache, etc., may be the chief disturbances, and may be recognised by their response, more or less prompt, to anti-syphilitic remedies as well as by their history or by the Wassermann reaction.

It may, indeed, be said that it is only by the indications just mentioned we may hope to identify the syphilitic character of nerve diseases, which are hardly distinguishable by any characteristic symptoms from those of non-syphilitic origin. A few points, however, may be mentioned, which are of assistance in diagnosis. In the diffuse type of

syphilitic basal disease severe paroxysmal headaches are an early sign, and are often worse at night. There is stupor and perhaps excitement, but more intermittent and less progressive than in ordinary tumours of the brain. The region of the chiasma and crura being often involved, we naturally find in many cases optic neuritis and oculo-motor paralysis. One or more muscles of the eyeball may be affected, and ptosis is common.

Treatment in these cases is that appropriate to the tertiary stage of syphilis—viz., iodide of potash, mercury by oral administration and by inunction, and salvarsan.

In illustration of certain of the above-named varieties of syphilis, the three cases before you, of which the following is a brief account, will be of interest.

Case 1.—D. F., a policeman, aged 30, suffered from syphilis about four years ago, and seems to have had fairly active treatment at the time. He gave a positive reaction to the Wassermann test. About six months ago he began to have headaches, not specially nocturnal: indeed, they were if anything worse in the morning, wearing off to some extent during the day. The headache was mainly frontal, but was also occipital. When the headache was at its worst he frequently vomited, without much sensation of nausea. About three months before admission to hospital he felt so ill that he went to bed, and has been bed-ridden practically ever since. About a month ago he says he had difficulty in expressing himself in words, though he did not lose consciousness, and he noticed that when the headache was severe he had pricking sensation in the left arm, in the shoulder, down to the fingers, and a similar feeling of "pins and needles" in his lips, better marked on the left side. He thought the power of his left hand and arm was deficient.

On admission there was no evidence of loss of power in any portion of his body. Tactile, painful and thermal sensibility were normal. Reflexes (including those of the pupils, bladder and rectum) were normal. His gait was normal, and he had no subjective symptoms referred to the legs. He still complained of the arm and lips as just described. His sight was defective, both for near and distant objects, and on examining his eyes choked disc was found on both sides. In this case the lesion was obviously intracranial and on the right side. The fibres of the motor tract, likewise those conveying sensory impulses, had suffered no interruption. The papillitis, together with the vomiting and headache, suggest tumour rather than a circulatory lesion, hence a gumma in the neighbourhood of the sensori-motor area of the right cortex is the probable diagnosis.

Case 2.—S. A., aged 38, a labourer. About 18 years ago he suffered from syphilis and was under somewhat intermittent treatment for about two years, during which time his health was far from good. He subsequently married, and his wife, though said to be healthy, has had no children. About four months ago the patient had to give up his work owing to pain of a darting or stabbing character round his chest. A year ago he began to lose control of his bladder, and has since then suffered from incontinence of urine. On admission to the hospital he was found to be fairly well nourished; his alimentary, circulatory and respiratory systems were in good order; his gait was slightly spastic, particularly as to the left leg; there was no definite loss of power, nor atrophy of muscles. His tactile sensation was normal, but his discrimination of heat and cold was imperfect in the legs and lower half of the trunk. Pain sense is normal. Reflexes: knee-jerks are increased, especially in the left leg; ankle-clonus absent; Babinski absent; abdominal and epigastric reflexes

present. The rectum is normal; there is incontinence of urine. A hypersensitive band is found on the thorax about three inches wide, encircling the chest about the level of the fifth, sixth and seventh dorsal vertebræ, and best marked on the left side. There is slight optic atrophy in the left eye. Wassermann positive.

The localisation of the lesion in the mid-dorsal region was fairly complete, and constituted a partial transverse obstruction of the cord, and at the same time supplied an irritative lesion to the nerve roots in its vicinity. The lesion may be diagnosed as a meningo-myelitis of specific origin in the mid-dorsal region of the cord. The perfect tactile sensation with defective thermal sense noted in this case is interesting, as some degree of "dissociated anæsthesia" has been described in cases of this nature.

Case 3.—A somewhat similar condition of affairs, but with important differences, is to be found in the case of J. M., aged 36, a van-driver, who had been in good health until ten years ago, when he had an attack of syphilis. He seems to have had a fairly efficient course of treatment. In May, 1911, he felt out-of-sorts and soon went for a holiday, but on returning he felt weaker than when he went away. He was unsteady in his gait and had shooting pains down his legs. He took to his bed in August, 1911. He complains of a pain in the small of the back, and a numbness from about three inches above the iliac crest to the toes. On examination, the alimentary, circulatory and respiratory systems are normal. In the nervous system the following changes have to be noted. There is loss of power of both legs, the right being the weaker; he is able to walk but with a spastic gait; the muscles of the legs are in a condition of tonic spasm. There is slight loss of tactile sensibility in the legs. The pain sense is unaffected. The reflexes are increased—viz., Babinski's sign is present; there is ankle clonus; knee-jerks are increased, and the supinator and other arm jerks are pretty well marked. There is complete incontinence of urine, and the rectum is only partially under control. There is no definite abnormality in the appearance of the fundus oculi. Wassermann's reaction is present.

The chief differences to be noted in this case from the previous one are, the absence of marked sensory symptoms, and the greater degree of transverse interruption of the cord. It is by the area of numbness or defective tactile sensibility, together with the increased reflex activity in the legs, that one can locate the lesion in that portion of the spinal cord immediately above the lumbar enlargement.

The sensory disturbance caused by interference with the posterior nerve roots in Case 2 are in this instance represented by a certain numbness, the lesion being, in other words, an obstructive rather than an irritative one, and the obstruction affects both the sensory and the motor impulses. While a similar diagnosis to the previous case (meningo-myelitis) is possible, the meningeal characters of the complaint are less obvious, and a specific myelitis or a gumma of the cord is the more probable lesion.

In all three cases, iodide of potassium, in doses of from half drachm to one and a half drachms per diem, together with mercury, is being administered, and a gradual, slight, but definite improvement has already been noted in each case.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Professor Lafforgue, M.D., *Médecin-Major, Val-de-Grâce, Paris.* Subject: "Pneumococcic Meningitis."

ORIGINAL PAPERS.

ON SOME OF THE RARER FORMS OF BREAST CANCER.

By W. SAMPSON HANDLEY, M.S., F.R.C.S.,

Senior Assistant Surgeon to Middlesex Hospital.

It would serve no useful purpose to repeat the familiar clinical facts about breast cancer which are to be found in the text-books, but there are certain anomalous forms of breast cancer which are yet sufficiently frequent to be of great practical importance. Moreover, it should be the aim of the practitioner to diagnose, or at least to suspect, breast cancer before the usual clinical signs are fully developed.

Whenever a tumour, a swelling definitely palpable with the flat hand, appears for the first time in a woman over forty, the spectre of cancer rises, no matter how innocent the characters of the tumour appear to be. Any such tumour should be at once explored, unless careful examination indicates that the swelling is due to chronic mastitis. The exception is an important one. Indurations due to chronic mastitis have very definite clinical characters, which enable a skilled observer to pronounce upon their nature with a near approach to certainty. Such patients form a considerable percentage of those who develop swellings in the breast after the age of forty, and they can be treated successfully, as a rule, without operation. The exploration of all cases of mammary induration as a routine measure is accordingly to be deprecated.

Let us now consider three forms of breast cancer in which some or all of the text-book symptoms, such as adhesion, retraction and elevation of the nipple, and enlargement of the axillary glands, may be absent.

EARLY CANCERS.

It may sometimes be possible to feel a carcinoma in such an early stage that the characteristic signs are absent for this reason alone. The presence of a small, hard swelling, more or less rounded in shape and fixed in the substance of the breast, will be the only fact observed. Careful manipulation fails to show adhesion to skin or fascia. Pain is conspicuously absent. The lump is single, and is not elastic nor fluctuating. The uncertainty of such cases can be resolved only by exploratory operation, and this should be undertaken without delay.

The exploratory operation should be a restricted one, made through a small incision. If an extensive operation is done, and especially if a tumour, presumed to be innocent, is removed by Gaillard Thomas's method of plastic resection, the difficulties in the way of a satisfactory subsequent operation for carcinoma, should it prove to be necessary, are almost insuperable.

MOBILE CARCINOMA.

Certain cancers, to which I have ventured to apply the term "mobile carcinoma" (a), exactly simulate a fibro-adenoma. In my experience a supposed fibro-adenoma, beginning after the age of forty, is more likely than not to be a cancer.

It is often wrongly assumed that all cancers become fixed in the substance of the breast, but this is not the case unless the growth is spreading at its margins by infiltrating the surrounding tissues. Certain cancers, instead of infiltrating, increase in diameter, mainly by a process of "centric" growth, that is to say, by pushing aside the surrounding normal tissues. Between the cancer and the sur-

rounding tissues a special layer of stroma is developed, which forms for the tumour a capsule almost as definite as that of a fibro-adenoma. The capsule may be complete even upon histological examination, and in such cases the tumour is quite mobile in the breast, and may even be enucleated without much difficulty. Such tumours are slow in acquiring adhesions to skin or fascia, and probably also in infecting the axillary glands. Clinically, they may thus be absolutely indistinguishable from a fibro-adenoma. At the operation the tumour, in some cases, shells out of its bed without much difficulty, though seldom so easily as a typical fibro-adenoma. In such cases microscopic examination is the only safeguard against a ghastly mistake which will probably be fatal. For although these tumours appear encapsuled, it is unlikely that their surroundings are entirely free from microscopic invasion, and recurrence near the scar is probable within a short time.

These exceptional cases of mobile carcinoma lead to conclusions of the greatest importance: (1) In women approaching the cancer age all rounded tumours of the breast, especially if single, must be at once explored, no matter how innocent they appear. (2) It is very easy to be content with a rough naked-eye examination of a tumour which is thought to be innocent. The omission of the microscopic examination of a presumably innocent tumour of the breast is a dangerous neglect of duty. All tumours of the breast after removal must be submitted to microscopic examination.

PERIPHERAL CARCINOMA.

A cancer may commence in an outlying lobule quite separate from the main body of the breast. It is possible that some of these outlying growths begin in supernumerary mammæ. In such cases there is rarely much difficulty in diagnosis, for the tumour, instead of being enveloped in a thick mass of fat, is very close to the skin on the one hand and the fascia upon the other.

Consequently, dimpling and adhesion to the skin and fixation to the fascia soon become manifest. The only danger is that the clinician may be misled by the small size of the tumour, and may estimate its importance accordingly. It is, of course, conceivable that an observer, unaware of the existence of this type of carcinoma, may regard the small dimple in the skin and the underlying tiny lump as of no practical importance, for the breast itself appears normal. In these cases early diagnosis is of especial moment, for the prognosis of peripheral carcinoma is worse than if the tumour is situated in the substance of the breast. There are two main reasons for this fact, one inevitable and one avoidable. Whereas a central cancer is separated from the ribs and intercostals by the whole thickness of the great pectoral, a peripheral cancer is likely to be separated from the ribs only by a relatively thin layer of muscle, through which permeation can more rapidly make its way. Infiltration of the chest wall proper and of the underlying pleura will consequently occur at an earlier date, and dissemination in the internal organs is correspondingly accelerated.

The second or avoidable reason for the bad prognosis of peripheral growths lies in the fact that they have not been excised upon sound principles. It is a fundamental rule of cancer surgery that the primary growth must always be at the centre of the area of tissue excised. This rule is a deduction from the permeation theory of dissemination. In the past it has been usual to deal with peripheral growths by almost the same operation which would be employed for a growth situated beneath the nipple. The line of section is taken very close to

(a) "Archives of the Middlesex Hospital." No. X.

the growth, and under such circumstances recurrence is very likely.

I have at present under my care a case of ulcerated peripheral cancer situated accurately in the middle line, just above the ensiform cartilage. The patient is an old lady of 65. The growth forms an irregular ulcer about an inch in diameter, with a sloughy base and hard raised edges surrounded by subcutaneous induration. The mass, which could be covered by a florin, is firmly adherent to the sternum, and therefore inoperable. Enlarged, hard, painless glands are present in both axillæ. Had the growth been operable it would have been necessary to clear out both the axillæ, for the median situation of the growth gives it simultaneous access both to the right and left axillary glands.

Among the unusual forms of breast carcinoma is the columnar-celled variety, which originates in the ducts. To the microscope duct cancer presents itself in two forms: one, that in which the growth originates in the large ducts; and, secondly, that in which the growth originates in the small ducts. The latter form is frequently indistinguishable from ordinary scirrhous of the breast, and need not here detain us, since it has only a pathological interest. Duct cancer beginning in the large ducts originally springs from an innocent duct papilloma, and there is accordingly a history of blood-stained serous discharge from the nipple existing for a period of some years before the patient seeks advice. Typical duct cancer is most frequently met with after middle age, and is of slow development and somewhat low malignancy. The tumour is generally found immediately beneath the nipple, which is not retracted; for a long time it remains mobile under the skin and upon the fascia, and there is no shrinkage or puckering of the breast. Moreover, the disease is slow in affecting the axillary glands. It will thus be seen that this form of cancer imitates, in many respects and for a long time, an innocent tumour of the breast. In an early stage a distinction may be impossible except by exploration.

ACUTE CANCER OF THE BREAST.

A terrible form of breast cancer, known as acute cancer or mastitis carcinomatosa, is fortunately rare. It is found only in comparatively young women who are healthy at the time of its development. This form of growth generally develops during lactation, although it may be found in the unmarried. The whole breast becomes enlarged and swollen, the skin shows an erythematous blush and is hot to the touch. It may be swollen and œdematous, and sometimes presents the typical orange rind appearance. The nipple may either be retracted or may be swollen by lymphatic œdema. In some cases it is only a portion of the breast that forms the tumour, and in such cases the swelling is sector-shaped like the indurations of chronic mastitis. It is only in acute carcinoma that the tumour presents this shape, which is otherwise characteristic of innocent conditions of the breast, and especially of chronic mastitis. Even in cases where only a part of the breast is at first involved, the whole breast is rapidly converted into a large tumour, which becomes firmly fixed over its whole extent, both to the skin and the fascia. Within a few weeks the thoracic wall may show the appearance of cancer *en cuirasse*. The thick and rigid skin, now immobile upon the chest wall, is covered with nodular growth. General dissemination rapidly occurs, and within from six weeks to three months after the onset of the disease the patient is dead. Operation in such cases is useless. Not infrequently acute cancer of the breast has been taken for mammary abscess, and has been excised

under this impression. It must be remembered that lymphatic œdema of the skin presenting the characteristic orange rind appearance may be present over a pointing mammary abscess; but while in the case of an abscess the *peau d'orange* area is a small one, in acute carcinoma the lymphatic œdema of the skin is co-extensive with the breast, and, moreover, the affected area of skin is often indurated from incipient cancerous infiltration and closely adherent to the underlying breast. The breast in this form of carcinoma is firmly fixed to the chest wall, which is not the case in acute mastitis.

INFLAMMATORY TUBERCULOSIS WITH NEOPLASTIC TENDENCIES: ADENOMA OF BREAST—TUBERCULOUS LIPOMA—COLD ABSCESS—LUMBAR AND THORACIC PULMONARY TUBERCULOSIS.

By A. PONCET, M.D.,

Professor at the Faculty of Medicine of Lyons,
[SPECIALLY REPORTED FOR THIS JOURNAL.]

HERE is a patient who presents a number of different pathological manifestations, different in appearance, in situation and in kind, yet which display a certain analogy between them in view of the pathological soil, which is particularly interesting in this instance.

This woman, 50 years of age, has for some years past developed various forms of tuberculosis. She is a striking example of the polymorphism of this disease, a point to which we have devoted a good deal of attention, so that it will not cause you surprise.

I will briefly recapitulate her numerous manifestations. Her pathological history dates back some eight years, as shown by a scar in the site of the left breast, which was removed at that date on account of an adenoma within a few months of its making its appearance. Some time after she developed a subcutaneous lipoma, now the size of a large almond, in the middle third of the left arm. It was then discovered that the patient had albuminuria, though this has long since disappeared after a few months' treatment.

Lastly, some four months since, she complained of lumbar pain, most marked over the spinous processes, followed soon after by the appearance at this spot of local tumefaction, which turned out to be a cold abscess, and subsequently gave issue to a certain quantity of matter leaving a persistent fistula.

A month after this another swelling of the same kind made its appearance at the lower angle of the left scapula, obviously involving the thoracic wall. It is this last swelling, which is tender on pressure, that brings the patient into our wards. It, too, was of the nature of a cold abscess, as shown by puncture, which we followed up by the injection of iodiform emulsion. The puncture gave issue to some serous grumous pus absolutely characteristic of a tuberculous abscess. To complete this brief description, I may add that the patient presents unequivocal signs at the apex of the right lung of a sclerous tuberculous lesion.

This, then, is the brief epitome of an important pathological balance sheet. The patient is pale, emaciated, and earns her living as a charwoman, which, I need scarcely remind you, is a laborious calling.

There do not appear to be any hereditary antecedents. She is married, and her husband, an engineer, is in good health. She has had two

children, one son, still alive, and a daughter, who died four months ago of acute meningo-encephalitis, which was, no doubt, tuberculous. We will now discuss the origin of all these manifestations, and enquire whether there is not one common cause for them all, different though their aspect be.

Not so many years ago, before research work on tuberculous articular rheumatism, and especially inflammatory tuberculosis of neoplastic tendencies, such a case would have been a riddle from the point of view of pathogenesis. Although certain of the lesions might have been diagnosed on the strength of their morphological characters to be tuberculous, the others would have baffled any aetiological explanation; indeed, no attempt would probably have been made to provide an explanation. Her case would have been summarised as adenoma of the breast, lipoma, albuminuria of unknown origin, in a woman who subsequently became obviously tuberculous.

Well, nowadays, gentlemen, we can grapple with the case in a much more satisfactory manner; we are in a position to assign the origin of these undetermined accidents, and refer them to one and the same cause, in this instance tubercle infection. It is already seven years ago that I wrote in reference to tuberculous rheumatism: "The rheumatism which we meet with in the tuberculous is not, as a rule, a simple coincidence, an intercurrent attack, and nothing more, a cause of tuberculosis. The rheumatic and tuberculous manifestations have the same pathogenesis, tuberculous intoxication, whence the term tuberculous rheumatism."

At present we can generalise on an even wider scale; indeed, we may state that every lesion, every pathological manifestation, whatever its form and seat, visceral or otherwise, supervening in a tuberculous subject, must, in the absence of any other assignable cause, be attributed to the tuberculous virus.

We go even farther, for clinical experience daily teaches us that tuberculosis may *ab origine* present itself in any organ, in any tissue, in any form, latent or subacute or hyperacute or chronic. It may assume a grave septicæmic aspect, and so be confounded with other infective diseases. Chronic, it often simulates arthritis, neuro-arthritis, etc., thus masking the true nature of the accidents which confront us.

Pray do not run away with the idea that these new doctrinal views are merely theoretical conceptions. On the contrary, they are forced upon us by daily experience of sick persons, by their heredity, their past history, by the absence of any plausible aetiological explanation, by the filiation of the symptoms, the sequence, etc. In many instances this pathogenic diagnosis is confirmed in the laboratory by the aid of bacteriological research.

It is by taking full notes, by scrutinising closely the patients' past history, by keeping them under observation for long periods of time, and by preserving an open mind, that we have arrived at a knowledge of the two main forms of tuberculosis described under the terms *septicæmic* tuberculosis and *inflammatory* tuberculosis.

Septicæmic tuberculosis, the forms of which range from trifling cases of tuberculous intoxication, ambulatory cases, to the most refractory, of variable gravity, sometimes rapidly fatal, but in all cases without any lesional reaction. In the second place inflammatory tuberculosis, which is associated with more or less extensive, grave lesions of ordinary inflammation, in other words, with specific anamalous reactions.

I shall not go more deeply into these two great varieties of tuberculosis, the existence and poly-

morphism of which are daily confirmed in practice. Nevertheless, it was necessary to recapitulate these considerations in order to explain the case before us.

As a matter of fact, I do not hesitate a minute to state that there is a common infection at the root of these various manifestations. What do we see? To begin with, a benign tumour of the breast, a mammary adenoma. Now this neoplasm, as I have shown in conjunction with Leriche, may, like other neoplasms of the same kind, in the thyroid gland, for instance, be of tuberculous origin. I need not insist upon the proofs that we have brought forward of this bacillary aetiology. Suffice it to state that inflammatory tuberculosis with neoplastic tendencies has been met with by other observers, whether adenomatous, lipomatous, etc., and that, on the other hand, we have collected numerous cases that confirm our views. For example, out of ten cases of mammary adenoma Leriche found that not less than seven were due to tuberculous intoxication.

And now as to the albuminuria from which this patient suffered. In all probability it was of the same origin. For many years I have taught that nephritis coming on spontaneously without any known or plausible aetiology is to be ascribed to tuberculosis, and that the so-called *præ-tuberculous* nephritis, whether fugitive or chronic, is really tuberculous.

I need not dwell on the cold abscesses starting in bone and the lesions in the right apex to which I have called attention. They are quite typical, and no doubt is possible in respect thereof. Nevertheless, they possess considerable importance in view of the retrospective diagnosis of the previous lesions, which did not afford, and could not very well have afforded, histological evidence of their tuberculous nature.

You must not suppose that patients of this kind are rare. We often meet with them in the surgical wards. I might state that such patients encumber the medical wards where, with more or less chronic lesions of the heart vessels, liver, kidney, etc., they are simply labelled cardiopaths, arterio-sclerosis, hepatic, renal, etc. Post-mortem examination in many of these cases reveals the fact that the patients are old-standing tuberculous subjects.

More than ever tuberculosis is the great disease. We must bear it in mind in presence of all spontaneous processes in which no other aetiology can be evoked. For the most part it is not, as generally believed, the terminal disease of a more or less long life, marked here and there by various discomforts and pathological states, consequent upon organic lesions of variable aspect; on the contrary, it is the original cause of all these troubles. It is the bacillary toxi-infection that must be incriminated.

SYPHILIS. (a)

By DAVID SOMMERVILLE, B.A., M.D.,
M.R.C.P.,

Hon. Physician and Pathologist, London Skin Hospital.

IN 1905 Schaudinn and Hoffmann described two spirochaetes in exudates from chancres. One large and coarse they named *spirochaete refringens*; the other thin, fine, and more difficult to see, *spirochaete pallida*. They considered the latter the parasite of syphilis, and the former a saprophyte. Schaudinn re-named the parasite of syphilis *Treponema pallidum*: this organism is now generally known as *spirochaete pallida*.

To demonstrate it, wash the *débris* from the patient's chancre with lint and normal saline, and

(a) Abstract of a paper read before the Aldershot Medical Society.

when the surface is quite clean squeeze out a drop of clear exudate. Pick this up with a clean capillary tube, and transfer it to a microscopic slide; apply a coverslip; place a drop of immersion oil on the under surface of the slide, and make contact with this and the upper surface of the parabolic dark ground condenser, so that total reflection of the oblique rays falling on the slide is prevented, and their focus obtained in the plane of the preparation. On lowering the $\frac{1}{2}$ in. objective, and adjusting the mirror, a number of brilliantly illuminated particles are seen against a dark background; cells and spirochætes appear intensely illuminated. Or Burri's Indian ink method may be employed: Sterilise some Gunther-Wagner's ink by steaming, and centrifuge until a film made from the upper portion of the column appears under the 1-12 in. objective quite homogeneous. Mix a loopful of exudate with a loopful of prepared ink, and spread on a slide. Dry the preparation without heat, and apply the oil immersion lens without a coverslip. The *S. pallida* appears as a white, wavy thread in a dark field. By this method motility is lost. Moreover, the width of the spirochæte varies according to the thickness of the film, and as more or less distortion must necessarily occur in all films, Burri's method is inferior to that of dark ground illumination.

By fixing the film of exudate in absolute alcohol, and staining for five or six hours with Giemsa's preparation, the *S. pallida* assumes a light rose-pink, and other spirochætes a blue tint.

Prior to Schaudinn's discovery Metchnikoff and Roux had studied experimental syphilis in the chimpanzee, and Uhlenhuth and Thomasczewski had followed the several stages of the disease in testicular syphilis of the rabbit, so that on discovery of the organism pathological and therapeutic research sped apace, with the result that we have acquired more accurate information concerning syphilis in the last half-dozen years than was obtained in all the previous ages of the history of the disease. An invaluable aid in this research has been the application of the Bordet-Gengou reaction to the diagnosis of syphilis by Wassermann, Neisser and Bruck. Bordet and his collaborator in 1901, whilst demonstrating specific antibodies in sera, noticed that when such an antibody was mixed with its antigen and complement *in vitro*, the latter disappeared from the mixture, so that in the case of red blood corpuscles no hæmolysis took place. On the other hand, when the serum did not contain the specific antibody of the antigen the complement did not disappear, and on addition of the hæmolytic amoceptor and corpuscles hæmolysis took place. They found that this prevention of hæmolysis could be turned to account in the demonstration of specific antibodies and antigens. Thus, if *B. typhosus* in the presence of an unknown serum could divert complement from a hæmolytic system, the serum must contain typhoid antibodies; and, conversely, if an unknown bacillus mixed with a typhoid serum caused diversion of the complement, the bacillus must be *B. typhosus*.

Wassermann and his colleagues in 1905 extended the work of Bordet and Gengou by showing that extracts of bacteria could be substituted for the corresponding bacteria without altering in any way the results. In 1906 they described syphilitic antibodies in the serum of syphilitised apes, and in the sera and cerebro-spinal fluids of syphilitic men. They used as antigen an extract of the liver of a congenital syphilitic fœtus. In the following year Levaditi and Marie showed that an extract of the liver of a normal fœtus performed the functions of antigen, so that some constituent of the antigen other than the spirochæte is obviously the active agent in the Wassermann reaction. The Wasser-

mann body is, therefore, not a specific immune substance destructive to spirochætes. Whilst Wassermann and his collaborators hold to the antigen-antibody theory, a large number of workers have shown that lecithin and other lipoids act as efficient antigens; so that whilst it is convenient to speak of the extract as antigen, it must be remembered that the syphilitic action is not due to an antibody to the spirochæte pallida acting in conjunction with its own receptors. When a watery extract of syphilitic tissue rich in spirochætes is used, it is highly probable that there is a reaction between spirochæte receptors and specific antibodies in the patient's serum; the fact of greatest importance, however, is that a syphilitic serum has acquired the power of reacting with certain bodies of known constitution so as to fix or "deviate" complement.

Julius Citron and others have sought to explain the reaction by assuming that the spirochæte forms a toxolipoid with lecithin in the cells of the body. This toxolipoid is analogous to Ehrlich's toxin, possessing a toxophore (spirochæte) group, and a haptophore (lecithin) group, and can give rise to antibodies in the serum. Thus, when an extract of syphilitic liver containing toxolipoid is mixed *in vitro* with syphilitic serum containing antibody and complement, the latter is fixed. In the case of the normal organ extract containing the lipid or haptophore group only, complement is also fixed as antitoxin is neutralised by Ehrlich's toxoid. That such antibodies, if produced, can have no destructive action on the spirochæte, and cannot produce immunity, is shown by the following facts: *S. pallida* mixed *in vitro* with complement and antiserum retains its infective properties; a chimpanzee injected with antiserum is still inoculable with syphilis; a chimpanzee injected with extract of syphilitic liver rich in spirochætes is still inoculable with *S. pallida*; primary syphilis cured with salvarsan does not result in the Wassermann reaction becoming strongly positive; the Wassermann substance is destroyed by temperatures much below those which kill true antibodies; it fixes complement at 0° C, a temperature at which no true antibody has been known to fix it; it is retained by a filter which allows true antibodies to pass. It appears from recent work that an addition of cholesterolin to lecithin increases the amount of complement absorbed in presence of syphilitic serum, but not in the presence of normal serum: these two bodies acting together in emulsion form a delicate test for the detection of syphilitic sera.

In performing the Wassermann test the following reagents are required: (1) serum to be tested, (2) antigen, (3) complement, (4) hæmolytic system, which acts as an indicator, and which consists of hæmolytic amoceptor and blood corpuscles, (5) 0.85 per cent. NaCl solution.

1. The serum to be tested is prepared from blood drawn from the patient's ear or elsewhere into a Wright's blood capsule of capacity 1 to 2 c.c. The capsule is centrifuged, and the serum removed by pipette, and inactivated by immersion in a water bath for half an hour at 55° C. The serum thus prepared may be kept in an ice chest for several days. Experience has shown that about 0.05 to 0.1 c.c. of serum is a convenient quantity to work with.

If cerebro-spinal fluid is to be tested the patient is placed on his side with his knees drawn up, so that the lumbar concavity is caused to disappear. A hollow steel needle three inches long is inserted in the middle line slightly below that spinous process which is on a level with the iliac crest, and is directed very slightly upwards firmly and slowly till the canal is reached. Should the needle become blocked it is cleared with a stilette. Twenty to thirty c.c. of fluid may be withdrawn; no blood

should be seen. The fluid is centrifuged, but not heated, as it does not contain hæmolytic complement. About 0.25 to 0.5 c.c. is used for the test.

2. The antigen first used by Wassermann was an aqueous extract of liver of a syphilitic fœtus. Owing to the unstable properties of the preparation the aqueous extract soon gave place to an alcoholic extract. Alcoholic extracts of various organs are now used with complete success. In using such extracts one must not lose sight of the hæmolytic action which it exerts by itself, of its anti-complement action, and of its power of absorbing complement in the presence of syphilitic serum: all these fallacies must be controlled.

3. The complement consists of the fresh serum of a guinea-pig, and is best used 18-24 hours after drawing the blood from the animal. In the interval it should be kept in the ice chest.

4. The hæmolytic amboceptor is obtained by inoculating a rabbit with sheep's red blood cells which have been thoroughly washed several times in 0.85 per cent. NaCl solution. When a high titre has been produced the animal is bled, and the blood placed on ice until the serum separates. It is then inactivated and sealed in capsules for use.

The corpuscles are prepared from fresh sheep's blood by centrifuging and washing thoroughly in a large volume of normal saline. The deposited corpuscles are finally made into a 5 per cent. suspension with normal saline, and of this half a c.c. is used in the test.

5. Recrystallised NaCl and distilled water are used to make a normal saline (0.85 per cent.). Syphilitic serum possesses in a greatly increased degree the power of fixing complement in the presence of certain lipoids—glycocholates, soaps, and lecithin prepared from liver and heart tissues. Cholesterin, as noted above, when added to lecithin, appears to act specifically in increasing the quantity of complement absorbed. Heating to 55 deg. C. for half an hour deprives all sera except syphilitic of the power of complement-fixation. There is some evidence to show that the reacting property of syphilitic serum is associated with its globulin content.

Whilst positive reactions have been obtained in frambœsia (*S. pertenuis*), relapsing fever, trypanosome infections, malaria, leprosy and other maladies, it appears that so far as diseases common to this country are concerned, the change in the serum which produces a positive Wassermann reaction is peculiar to syphilis, and fully 90 per cent. of cases in which active syphilitic lesions exist give the reaction. Whilst a negative reaction, even when carefully elicited, does not definitely exclude syphilis, experience has shown that it is most unlikely that a negative reaction will be obtained repeatedly where active syphilitic lesions are present. The Wassermann reaction has been of the greatest service in demonstrating the true syphilitic character of the so-called parasymphilitic affections. Neisser has conclusively shown that "immunity" to syphilis, as presented in parasymphilitics and the women of the "law of Colles," is due to the presence of living spirochætes. The fact that more than half the cases of latent syphilis react positively is of the greatest moment, as infectivity may exist over a very long latent period.

The Wassermann reaction is a measure of the power of a serum and antigen to fix complement: it is, therefore, necessary to standardise all the reagents. Since the strength of the hæmolytic amboceptor, when once estimated, does not appreciably vary, it is convenient to take it as the constant.

Hæmolytic system: A series of dilutions of amboceptor serum in saline is prepared, and into each tube is measured a definite quantity of com-

plement (say, .1 c.c. of a 1 in 4 dilution), and half a c.c. of a 5 per cent. suspension of sheep's corpuscles, and the whole is put in a 37 deg. C. incubator for half an hour. That tube is selected as containing the minimal hæmolytic dose or unit in which the smallest quantity of amboceptor has produced complete hæmolytic action. In the test some experimenters use five times and others two-and-a-half times this unit. In the same manner a series of dilutions of complement serum is prepared, and half a c.c. of 5 per cent. suspension of corpuscles sensitised with, say, 2½ units of amboceptor is added to each tube, and the whole incubated for half an hour. The minimal hæmolytic dose is then observed, and 2½ times this unit is used in the test.

Antigen: As in the case of the amboceptor and complement sera quantities of saline are placed in a series of tubes, so that on the subsequent addition of antigen the volumes are equal. Convenient quantities of alcoholic heart extract may run between 0.05 and 0.15 c.c. The antigen is pipetted on the surface of the saline, and the two fluids rapidly shaken together. Complement is then added, and the mixture again shaken and incubated for half an hour. Lastly, 2½ units of amboceptor and half a c.c. of 5 per cent. suspension of corpuscles are added and incubated for a quarter of an hour. The smallest amount of antigen is observed which, by absorbing complement, completely inhibits hæmolytic action. Half this quantity produces complete hæmolytic action, and is convenient for the test.

In executing the test two test-tubes are used for the serum under observation—two for a normal control serum, and three for *technique* controls.

The saline and antigen are shaken immediately the latter is added. On addition of complement the tubes are again shaken and incubated for half an hour at 37° C. The corpuscles are then added, the tubes again shaken and incubated for a quarter of an hour. Lastly, the tubes are placed on ice, allowed to deposit for two hours, and results observed. If hæmolytic action occurs in tube 1, the reaction is negative. If no hæmolytic action occurs in tube 1, the reaction is positive. Complete hæmolytic action occurs in tubes 2, 3, 4, 5 and 6. No hæmolytic action appears in 7, demonstrating that the corpuscles have been washed free from complement, and that they do not lake spontaneously.

Tube 2 shows that the patient's serum alone does not prevent hæmolytic action; tube 3, that normal serum mixed with antigen does not inhibit hæmolytic action; tube 4, that normal serum alone does not prevent hæmolytic action; tube 5, that antigen alone does not inhibit hæmolytic action; and tube 6, that the amounts of complement and sensitising amboceptor are sufficient to produce rapid and complete hæmolytic action.

In this as in many other biological reactions it is difficult to state at all times whether a particular degree of inhibition of hæmolytic action warrants the diagnosis of a positive reaction. In sera examined for the first time it is well to return as positive only those that give definite results; in sera previously found to be positive slight inhibition of hæmolytic action (more especially if the patient be under treatment) may still be returned as positive.

In using antigens composed of alcoholic extracts of organs the emulsion of saline and antigen should be made so as to procure the maximum turbidity, since a turbid emulsion adsorbs more complement. As alcohol, when mixed in sufficient quantity with saline solution, can destroy complement, it is necessary to attend carefully to the quantity used in the preparation of antigens, and also to the standardisation before use of all such antigens in the presence of both normal and syphilitic sera. In this connection it has been found that liver lecithin and

cholesterin form an efficient substitute for alcoholic organ-extracts.

Never, perhaps, in the history of biological science has fruitful research progressed so rapidly as in experimental syphilis during the last six years. The discovery of the spirochæte by Schaudinn in the primary sore was followed almost immediately by the Wassermann reaction which detects it in the most distant and inaccessible tissue, and hard upon these came Ehrlich's chemo-therapeutic agent, dioxy - diamido - arsenobenzol, which kills the organism. The experimental work done in animals by Ehrlich and Hata on relapsing fever, fowl spirillosis, and syphilis in rabbits, had brought to light three classes of chemical compounds more or less curative in trypanosomiasis and spirillosis before they commenced their research on the chemotherapy of syphilis in man—viz., compounds of arsenic, such as atoxyl, arsacetin, arseno-phenylglycin; benzidin azo dyes, such as trypan blue, trypan red, trypan violet; and triphenyl methane dyes, such as methyl violet and fuchsin. Of these the arsenical compounds gave the best results. According to Ehrlich's account of the work, the starting point was atoxyl, which was shown by Bertheim not to be an anilido derivative of arsenic acid, as had been previously stated, but the sodium salt of para-amido-phenyl-arsenic acid

By diazotising para-amido phenylarsenic acid Bertheim obtained para-oxypyphenylarsenic acid,

which body can also be obtained by acting on phenol with arsenic acid.

By nitrating and afterwards reducing para-oxypyphenylarsenic acid he obtained the dioxydiamino body as a condensation of two molecules.

The di-hydrochloride of this compound is the salvarsan of commerce. Bertheim believes that the para position of the OH group is correlated with the spirillicidal action of the compound. The NH₂ group in orthoposition to OH was found to largely increase the therapeutic efficiency. The spirillicidal efficiency is also increased by the pentavalent arsenic in para-oxypyphenylarsenic acid becoming trivalent in dioxydiamido-arsenic-benzol.

The drug must be rigidly shut off from the atmosphere and prepared for injection immediately before use, otherwise it oxidises to poisonous compounds. It dissolves in water or dilute saline, producing a strongly acid solution. In the early days this irritating and toxic solution was injected intra-muscularly and intra-venously with bad results. A mono-acid solution—i.e., the solution obtained by

adding half the amount of alkali necessary to produce complete neutralisation—is also irritating and toxic.

The neutral suspension obtained by the addition of just sufficient alkali to produce neutrality has been used by Wechselmann and others, but in many cases pain was marked and absorption slow.

The alkaline disodium salt used by Hata in his early experiments is the best form for use. The full dose (0.6 gramme) of salvarsan is dissolved in 15 c.c. normal warm saline in a sterile mortar; ten per cent. NaOH is slowly added, drop by drop, whilst the precipitate which forms is rapidly ground with the pestle. A single drop more of NaOH than is necessary to dissolve the precipitate (about 1.5 c.c. in all) is used, otherwise on cooling a trace of precipitate may fall out. The dose is thus brought into solution in a volume of 15-20 c.c., a convenient volume for intra-muscular injection. For intra-venous injection, which is now most used, the 15-20 c.c. are diluted to 300 c.c. with warm normal saline. It is important that the patient's alimentary tract be in good condition, and that he receive the injection in bed. Transitory symptoms occasionally occur, such as nausea, slight rigor, rise of temperature to about 101 deg. F. or 102 deg. F., but the injection, as a rule, is followed by a sense of well-being. The arsenic is excreted partly by the urine and partly by the fæces, in cases of intra-venous injection for three or four days, and in cases of intra-muscular injection for several weeks.

It is still too early to speak of the permanent effects of the drug, much less to make claims for its powers of complete cure. But the curing of lesions in primary and secondary syphilis is frequently marvellous, extensive chancres heal in a day or two; large mucous patches vanish in 24 hours; condylomata, macular and pustular syphilides, and ulcers, which were quite refractory to mercury, disappear in a few days. The literature already records some thousands of cases of the most rapid cure of ulcerating malignant forms of syphilis.

Wechselmann has obtained equally good results in tertiary conditions in viscera, testicular and laryngeal gummata, syphilitic epilepsy and gummata of the brain. From the treatment of more than 1,500 cases he is convinced of the great superiority of salvarsan over mercury. His results in tabes and general paralysis are not so remarkable; the permanent damage already done cannot be repaired. Michaelis and his collaborators have had excellent success in treating congenital syphilis in infants, working for the most part with doses of 0.05 gramme salvarsan.

Perhaps the most important evidence in favour of the view that salvarsan produces complete sterilisation is the recurrence in treated cases of re-infection with syphilis. Apart from what has already been done by Ehrlich and Bertheim's synthetic drug, the unbounded hope of possibilities in therapeutics for similar syntheses stamps this research as one of the most important pieces of scientific work of modern times. It has opened the door to the manufacture of synthetic disinfectants. Along similar lines Morgenroth has been able to cure with such a synthesised drug 50 per cent. of pneumococcal septicæmias in mice; and Wassermann has recently published an account of the action of his compound synthesised from selenium and eosin on experimental cancer in mice.

A modification of salvarsan, neosalvarsan, has recently appeared, and bids fair to oust the original body. The preparation is obtained by introducing a sulphoxyl radicle through the agency of acid sodium formaldehyde sulphoxylate CH₂(OH)O.SO.Na.

One such group is attached to an amido-radicle with elimination of water, thus

forms a yellow powder less fine than salvarsan. A dose of .9 gramme is said to be borne as well as .6 gramme salvarsan. It also readily oxidises into a highly toxic compound, turning in colour from orange yellow to yellow ochre. The above dose dissolves readily in 150 c.c. distilled water at 30 deg. C., forming a clear solution ready for venous injection. There is no doubt that the outlook for chemo-therapy is bright.

A CASE OF ACUTE PERFORATION OF THE STOMACH;

WITH AN ANALYSIS OF CERTAIN PREDOMINANT SYMPTOMS. (a)

By JOHN H. WATSON, M.B., B.S.LOND.,
F.R.C.S.ENG.

Burnley.

It is now common surgical knowledge that perforations of gastric ulcers are a frequent cause of acute abdominal suffering—ending sooner or later in death in most instances, unless relief is obtained by timely surgical assistance.

We are also aware that ulcers on the anterior wall are much more liable to perforate than those on the posterior; moreover, we know that the leakage of gastric contents following such a rupture is more prone to diffusion in the anterior lesion, hence they are more perilous to life. We cannot, however, with certainty differentiate between anterior and posterior perforations, nor is it necessary to do so, but we do realise the absolute importance of an early diagnosis and immediate operation. Practically, the life of such a patient depends upon the diagnostic acumen of the medical man who is first called in attendance. There can be no more critical time either for patient or doctor. The doctor who hesitates and spends time in repeated examinations or defers many hours for the arrival of the specialist, gravely endangers his patient's life, and may easily forfeit it. Late operations show a very heavy mortality, and no wonder the surgeon grumbles.

That there is room for hesitancy and doubt in such a crisis one is obliged to admit, and we may exonerate ourselves in case of mistaken diagnosis by quoting some positive statements of symptoms from one or other surgical work which certainly were not evident in our own patient.

The accounts we are accustomed to of acute abdominal disease are by no means infallible, very often a more or less disorderly collection of symptoms with no regard to their relative importance, and sometimes even tending to lead one astray. For this reason I have recorded this case in detail and attempted to analyse it from Mackenzie's point of view, namely, that in visceral disease "the most important class of symptoms arise from the involvement of the nervous system—when a stimulus arising in some viscus passes into the central nervous system, and there acts on the nerves supplying other organs, exciting the function peculiar to them."

The patient, G. H. F., was a male æt. 58 years, and occupied as an itinerant dentist.

History of present illness.—On the night of November 15th, 1910, he had supper at about 10 o'clock, consisting of a basin of bread and milk, and shortly after went to bed feeling quite well, but about 11 o'clock he awoke with most violent pain in the pit of his stomach. With the assistance of his wife he got up and was able to go downstairs into the kitchen and rest on the couch. Dr. Clegg, of Rosegrove, was sent for, and found him suffering from such intense

pain than an opiate was given but with practically no relief. I saw him with Dr. Clegg, 12.15 a.m.; he was still on the couch, lying on his back in a semi-recumbent posture. His face appeared pinched and pale, beads of perspiration stood out on his brow, and his skin felt cold and clammy; he had vomited, and was still retching a great deal and seemed exhausted from the effort. He answered our questions quite well, but in a whispering voice, and was evidently disinclined to talk except to plead for something to ease the pain. Both he and his friends declared that he went to bed perfectly well. On examination: a spare man of poor muscular development. Pulse 68, regular and a good forcible beat. Respiration 24, shallow and thoracic entirely. Temperature 98.4. Abdomen motionless, supra-umbilical region tender and board-like; over this part the patient could not bear percussion, and the area to the right and just below the costal margin was so exquisitely sensitive that the slightest pressure caused him to shout. There were also periodic exacerbations of the pain. Knee reflexes were present. No evidence of plumbism. Our diagnosis lay between perforated ulcer of stomach or of the duodenum; but we felt some uncertainty still chiefly on account of the excellent condition of his pulse. As the relatives were anxious to consult before permitting his removal to hospital, we determined to see him again in about an hour's time.

When seen at 2 a.m. he was certainly not so well, pulse rate increasing 84, respiration still quick, and pain constant. His removal to hospital was agreed to, but owing to delay in transport he did not reach the Victoria Hospital, Burnley—about four miles away—until about 5 a.m. His pulse was, on admission, 100, respiration 30, temperature 97. Operation at 5.45. Anæsthetic—chloroform followed by ether. An incision was made slightly to the right of the mid-line through rectus from ensiform to umbilicus. On opening the peritoneum there was an escape of gas and then of turbid fluid. The anterior wall of stomach was first explored, secondly the duodenum, and at once from the right kidney pouch a quantity of semi-purulent fluid curd and food debris welled up. This was rapidly mopped up, but no perforation seen; a finger inserted through foramen of Winslow immediately came upon a thickened area with a central perforation. The transverse colon was turned out, the gastro-colic omentum split, and the perforation exposed; it was observed to be situated near the lesser curvature and close to the pylorus, about $\frac{1}{4}$ inch in diameter, cleanly punched out, and in the centre of an indurated area, about the size of half a crown. The hole was closed with two through-and-through catgut sutures, extra strain being avoided owing to the friability of the neighbouring tissues, and a superimposed layer of four fine silk lembert sutures inserted, a small graft was turned back from the adjacent posterior layer of the lesser omentum and fixed in position over this area with catgut.

The upper abdomen was then well flushed with saline and about two pints left behind. The abdominal wall was closed with silkworm gut in haste and without anæsthetic as the pulse became imperceptible. The operation took about three-quarters of an hour. For the first day his recovery was doubtful, he rallied on the second day, afterwards making an uneventful recovery. He left hospital in three weeks, and has been up to the present time perfectly well.

In presenting this case, the special features I have attempted to analyse and explain are:—

I.—The site and nature of the pain.

II.—The board-like rigidity of the upper abdomen.

III.—The condition of the pulse.

I. The site of the pain in this case the patient indicated with the palm of his hand, and is shown in the diagram (fig. 1) as the deeply stippled area, situated in the epigastrium to the right of the mid-line, corresponding anatomically to the distribution of the anterior terminal cutaneous branches of the 7th dorsal nerve particularly; in fact, so great was the sensitiveness over this area that the slightest touch made him shout. In addition, there was general tenderness over the upper abdomen corresponding to

the distribution of the 6th, 7th and 8th thoracic segments, and this was noted to be more marked to the right of the mid-line (*vide* fig. 1).

Dieulafoy, quoted by Lejars, refers to this acute intense pain, which he describes as atrocious, and localises it at the onset in the sub-hepatico-gastric region above and to the right of the umbilicus.

Now, as to the nature of the pain, both Mackenzie and Lennander maintain that the viscera are insensitive to pain. Lennander states from his observation that the parietal peritoneum is very sensitive to pain, and also that the parietal peritoneum about the fora-

FIG. 1.—Diagram showing belt of cutaneous hyperalgesia in upper abdomen, practically over area of distribution of 6th, 7th, and 8th thoracic segments. The right half being more sensitive than the left, the site of maximum tenderness is indicated by the coarsest stippling.

men of Winslow, and the lower opening of the thorax along the costal cartilages, is especially sensitive. Ramstrom, in corroboration, has demonstrated an exceedingly intricate plexus of nerve fibrils and endings in the parietal subserosa derived from those nerves supplying the adjacent parietal muscles. Lennander therefore believed that the visceral pain is the result of an inflammation involving the parietal peritoneum either by contiguity, the spread of toxins, or the inflammatory process along the subserosa; and in hollow muscular viscera, as the stomach, is the effect of muscular spasm exerting traction on the subserous tissue and indirectly on the cerebro-spinal nerves of the abdominal wall.

Mackenzie puts forward the view that the pains arising from a viscus are not felt in the organ, but are referred to the peripheral distribution of the cerebro-spinal nerves in the external body wall. He assumes that if a sensory nerve be stimulated in any part of its course through the brain, spinal cord, or trunk of the nerve, the resultant sensation is referred to the peripheral distribution of the nerve in the external body wall; so that if a morbid process in a viscus gives rise to an increased stimulus of the nerves passing from the viscus to the spinal cord, this increased stimulation affects neighbouring centres, and

so stimulates sensory, motor, and other nerves that issue from this part of the cord, and thus an irritable focus is produced, and consequently such stimulation of a sensory nerve in the focus will result in pain referred to the end organs of that nerve, so that visceral pain is really a viscerosensory reflex. In his book on *Symptoms and their Interpretation* he gives clinical evidence in support of his assertion that the most severe pain of which we are conscious can be produced by the violent contraction of hollow muscular organs, and that this pain is not felt actually in the viscus, but is referred to the sensory nerves in the external body wall arising from those segments of the spinal cord supplying also the contracting viscus.

Hertz, in his Goulstonian Lectures (1911), concludes that there is such a thing as true visceral pain, the cause being tension upon the muscular coat of the hollow organs. He says, in the case of the stomach, that abnormally strong peristalsis causes an excessive rise in the internal pressure in the pyloric end of the stomach, and the tension on its muscular fibres gives rise to pain. This hardly explains the cases I have seen in which a pyloric ulcer had perforated. The tension in such a case should be lessened, for there is a free exit for stomach contents into the peritoneum, and yet the pain is intolerable.

To my mind, Mackenzie's viscerosensory reflex gives us the best working hypothesis as to the nature of the pain. The onset is far too quick—the patient is struck almost as if he had been shot with a gun—to accept Lennander's irritation or spread of inflammation theory, which would take some time.

We may now revert to a question difficult of explanation, namely, why should the superficial tenderness be so much more marked on the right side. I see no reason that we may not assume that the efferent visceral nerves from this particular damaged portion of the posterior wall of the pyloric end of the stomach are connected with the right half of the spinal cord in the region of the 7th dorsal segment particularly. We are, of course, aware that the anterior surface of the stomach is supplied by the left vagus and the posterior by the right vagus, and on anatomical and embryological grounds it is conceivable that a similar distribution might be the case with the sympathetic; although so far as I know it has not been demonstrated. If such were the case, an explanation would be apparent; but even without this, if we accept Mackenzie's theory of an irritable focus confined to one or more segments of the spinal cord, it does not require a great stretch of the imagination to comprehend that if the right half of the segment is receiving more intense stimuli than the left, the right half will become more irritable and the viscerosensory reflex of that side stimulated to a higher and consequently more sensitive degree; and this is what we should expect on physiological and histological grounds.

The following diagram (fig. 2) will, I hope, serve to make the idea clearer.

II. The muscular rigidity was most noticeable about the upper halves of recti abdominis. It is common anatomical knowledge that these muscles above the umbilicus receive their nerves from the 5th to the 6th thoracic segments, and the overlying skin is supplied by terminal branches of these nerves, which traverse the muscle and, after supplying it, pierce the anterior sheath somewhere midway between the linea semilunaris and the linea alba.

These nerves also supply the respective intercostal muscles and the upper two or three digital origins of the obliques and transversalis abdominis. Now on the deep surface of these flat abdominal muscles we have the subperitoneal tissue, which, as previously stated, contains an extraordinarily intricate development of nerve fibrillæ and their endings, derived from those nerves supplying the superjacent flat muscles of the abdominal wall. (Ramstrom.)

So that practically from any one of these segments of the spinal cord, we have corresponding segmental supply of muscle, skin, and subserosa. The visceral nerves of the stomach are also derived from these mid-thoracic segments, and in our damaged viscus the in-

FIG. 2.—Diagram to illustrate the concept of a viscerosensory and visceromotor reflex.

Stimuli from the lesion (L.), in the posterior wall of the stomach (S.), pass by the splanchnic nerve (Sy.af.), reach the right half of the spinal cord (Sp.C.), and there give rise to an irritable focus in the cord, which is most intense in the right-half segment, and is indicated by coarser stippling. The neighbouring cells and centres are stimulated to activity, viz., (a) an efferent sympathetic fibre (Sy.ef.), having its origin in this area, conducts impulses to the muscular wall of the viscus (S.); (b) motor impulses to the voluntary muscles of the abdominal wall supplied by this segment, via the efferent somatic nerves (Som.af.) = visceromotor reflex; (c) sensory impressions are referred by the afferent somatic nerves belonging to the segment to (1) the skin (D.), resulting in cutaneous hyperalgesia, (2) the subperitoneal tissues (S.P.) = increased sensitiveness, (3) the muscles (Vol. M.) = muscular hyperalgesia; the general effect = viscerosensory reflex.

(The thick lines indicate the path of impulses to external body wall; the fine lines the path of visceral or sympathetic impulses.)

tensity of the afferent impulses to the mid-dorsal cord are sufficient to bring about an irritable focus (Mackenzie); this increased stimulation again excites neighbouring nerve-cell groups, and consequently the anterior horn cells of the segments involved respond, and we get an immediate almost tetanic contraction of the muscles innervated from this area. As a result, we observed the board-like rigidity of the upper abdomen, the fixity of the lower chest, and secondarily the more rapid compensatory breathing of the upper thoracic type.

In Mackenzie's own words we have, "the contraction of voluntary muscles in the external body wall in response to a stimulus arising from a viscus," and this phenomenon he terms a visceromotor reflex.

III. We now come to the condition of the pulse, which was found to be 68 and of excellent tension—with our diagnosis of a perforation, a condition of pulse not to be expected if we are guided by the textbooks. One recent writer goes so far as to say that a normal pulse practically excludes all cases of ruptured viscera; however, Moynihan, in a most able article on the "Acute Emergencies of Abdominal Disease," says the pulse will be found at the first to be hardly altered in frequency or in volume, and quotes a case in consultation in which he deliberately postponed operation for some hours. I know of two other similar cases which unfortunately ended in

disaster simply because the pulse was normal and therefore the aptly termed "mythical shock," the sign or symptom-complex for which we are instructed to look out above all others in an abdominal catastrophe of this nature, was not present, and I believe that to most practitioners the essential feature of this so-called shock is a rapid feeble pulse, hence the frequency of late diagnosis and consequent disasters.

Crile and Mummery both maintain that the essential phenomenon of the state designated surgical shock is an abnormally low blood-pressure. Unfortunately I had no manometer for an observation on my patient, but I am confident there was no diminished blood-pressure, but rather the reverse; therefore there was no shock to begin with, and this bears out what I want to suggest: first, that the efferent fibres conveying impulses from the stomach to the mid-dorsal cord excite the subsidiary vasomotor centres in that area, and thus bring about what may be called a viscerovasomotor reflex. This soon becomes general, for we have in addition the intense stimulation of the afferent sensory nerves of the upper abdomen as previously stated. These on their way up to the brain (see diagram, fig. 3) will excite the vasomotor centre in the medulla, and consequently the primary effect anticipated would be a rise in the blood-pressure. This persistent and ever-increasing excitation from the spread of peritoneal irritation as a consequence of leakage from the stomach can only end sooner or later in exhaustion, the result of which is, of course, loss of tone of the vessels and consequent dilatation.

FIG. 3.—Diagram to illustrate the concept of a viscerovasomotor reflex.

Stimuli from lesion (L.) in stomach walls (S.) pass by splanchnic afferent nerve (Sy. af.) to spinal cord, and are of sufficient intensity to cause an irritable focus at I.F., from whence proceed vasomotor impulses to blood-vessels (Art.), via pre- and post-ganglionic sympathetic fibres (po. and pr. g.f.); in addition somatic afferent fibres are stimulated in the same area (Som. af.), and, in their passage up to the cerebrum, stimulate also the subsidiary (S.V.M.C.), and the principal vasomotor centres (V.M.C.). Sk. = skin; M.S. = muscle spindle; I.C. = intercentral fibre.

There is yet another factor which may be considered as tending to bring about early vaso dilatation.

It has been shown that stimulation of the nerves distributed to the muscles, or even the muscles themselves, causes a depressor effect upon the blood-pressure, thus proving the presence of afferent fibres in the muscles. It is therefore conceivable that the extreme contraction of the recti and the other abdominal muscles stimulates the muscle spindles they contain (which are stated to be the end organs of the afferent nerve fibres in muscles (Sherrington), and so accelerate the onset of vaso dilatation.

The question now arises, why should the blood stagnate in the abdominal veins. Malcolm has suggested that the superficial vessels are first constricted, and, if the exciting cause is kept up, the large vessels contract and the blood is driven into the tissues and back into the abdominal veins. Looking at the question from the point of view of a viscerovasomotor reflex, afferent vasomotor impulses from the stomach excite the subsidiary vasomotor centres in the mid-dorsal cord, and pressor impulses are referred *via* the splanchnics and celiac ganglion, thence to the visceral blood-vessels; and as the lesion is in the stomach, it may be assumed these subsidiary centres will be the first to be excited, and will also be the first to tire, consequently the blood will tend to dilate these toneless vessels first. Other physical factors, such as the lessened aspiratory influence of the thorax, and the total absence of abdominal movement, will of course increase the stagnation, and hence we get more or less rapid bleeding into the splanchnic vessels.

The rapid action of the heart which now takes place is a natural physiological sequence consequent upon the great reduction in the actual work done by each beat, because the heart is receiving less blood and also the quantity propelled at each beat is diminished. Moreover, there is an alteration in the quality of the blood it receives, the viscosity being lessened. And lastly, there follows the greatly diminished peripheral resistance accompanied by a fall in the blood-pressure, and these are the concomitant factors which are synonymous with the surgical nightmare called shock.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

CASE OF EMPYEMA.—MR. WILLMOTT EVANS operated on a case of empyema. The patient was a woman, *æt.* 35, who had had an attack of pneumonia a fortnight before, but just after the crisis the temperature rose again, and ever since she had had an irregular temperature, pain in the right side, and a troublesome cough. On examination, there was dulness of the right side reaching upwards from the liver dulness to the upper border of the fourth rib. There was absence of vocal resonance and of vocal fremitus, and by measurement the right side of the chest was two inches more than the left; the cough was troublesome; there was very little expectoration. The patient was unable to lie down in bed at night, the breathing was quickened, the pulse 120, and the temperature of a hectic type. A diagnosis of empyema was made and operation decided on. A needle was inserted into the eighth intercostal space and pus found.

An incision was made on the right side just in front of the posterior axillary line, about two inches in length, over the eighth rib. The tissues were turned back from the rib and the periosteum stripped up for a length of about one inch. Then, with a pair of rib forceps, an inch of rib was removed. An incision was then made through the space, the pleura was opened, and creamy pus came away; in all about two pints were evacuated, and then a drainage tube was inserted, which consisted of two rubber flanges connected by a piece of rubber tubing about an inch in length, so that one flange rested on the skin and the other was just within the pleural cavity. No attempt was made to wash out the cavity. Gauze dressings were applied and the patient returned to bed.

Mr. Evans said that the diagnosis in this case was

clear, for an acute attack of pneumonia was followed almost immediately by the signs of pleural effusion, and at the same time the irregular temperature pointed to the presence of pus, but in all cases it is advisable before operating for empyema to confirm the presence of pus by an exploring syringe at the site where the incision is about to be made. As to the nature of the empyema, he pointed out that there can practically be no doubt that it will prove to be pneumococcal in nature. With regard to the site of the incision, it is, he thought, desirable to place it in that position which will be best for drainage, and as it would be necessary for the patient to remain in bed the drainage opening must be towards the back of the thorax; yet, if it be placed too far behind, the opening will be closed when the patient is in the recumbent position, and this will interfere with drainage; therefore the most convenient position is immediately in front of the posterior axillary line. The question of the level at which the opening should be made is also, he considered, important: if it be made too high up the empyema will not drain well, while if it be made too low down, the rising of the diaphragm, which always occurs as the chest wall falls in, will block the opening before the empyema has healed; therefore the level of the eighth rib is about the most suitable site. Again, the question has to be considered whether it is necessary or not to resect a portion of the rib; it cannot be said to be essential in all cases, for many patients recover after a simple incision, and especially is this the case with children; but, on the other hand, the falling in of the chest wall brings the ribs closer together, and this may lead to nipping of the tube, so that on the whole in adults it is better to resect a portion of the rib. It is sometimes recommended, he remarked, that the pleural cavity should be washed out with an antiseptic solution, especially if the pus has been fetid. In a certain number of cases immediate death has followed the practice of washing out the pleura, and although it is difficult to speak with certainty as to the cause of this, it is probably due to the shock produced by the use of too cold or too irritating a solution; moreover it is not necessary, for however fetid the pus may be at the time of incision of the empyema, it will become perfectly sweet within two or three days. The use of a drainage tube, Mr. Evans considered, was important, but it is undesirable to employ a long tube such as is often used, for it does not hasten the closing of the cavity—in fact, it may retard it. All that is needed is that the inner opening of the tube should reach to the pleural cavity. The prognosis of this case, Mr. Evans said, was good because it was almost certainly pneumococcal in origin, for pneumococcal empyema had a much better prognosis than other forms of the disease.

The patient recovered rapidly. At the end of a week pus ceased to be discharged; the tube was removed a day or two later, and at the end of a fortnight the woman was able to go to a convalescent home with the wound almost healed.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, Sept. 21st, 1912.

At the Gesellschaft für Psychiatrie und Nervenkrankheiten, Hr. Bonhoefer showed a boy, *æt.* 9, who presented the symptoms of

CEREBELLO-BULBAR PARALYSIS.

When the boy was first seen at the polyklinik, symptoms of chorea were to the front. Some disturbance of speech even then, however, gave indication that there was something else in the background. At the commencement of the illness the first thing noticed was a certain restlessness in the right hand, and that there was failure to grasp objects firmly with it. These movements gradually made both eating by himself and writing impossible. Then

speech became affected. On admission into hospital, along with the movements named there was a pronounced ataxia, worse on the right than on the left, a stumbling gait, with a tendency to spread out the legs, but without any spasm of the adductors. The tonus of the right upper extremity was also distinctly lowered. The movements of the right hand, the fingers and the arm were clumsy. Power was well retained on the arm. There was pronounced adiadochokinesis of the right side, with difficulty in opening the hand after it had been closed, as in myotonia. There was no change as regarded passive movement in the lower extremities, sharp tendou reflexes, no change of the plantar reflex. Slight ataxic disturbance of the right leg, less than in the right arm, no change in the left side. The sense of locality was undisturbed in the upper extremity and also over the abdomen. Muscles of the face paretic on both sides, speech distinctly nasal with disturbance of articulation, but not so much so as to prevent his being understood. The pupils were natural, no signs of pressure, the sensorium quite free. Lumbar puncture gave a strong globulin reaction, slight increase of the lymphocytes, Wassermann reaction negative, even with increased quantity of fluid. During a stay of eight weeks in hospital the condition got worse as regarded gait and speech. At present the boy could scarcely speak at all. Swallowing was difficult, and there was scarcely any movement of the tongue. No change in electrical excitability in the faciolingual region. The tongue was not atrophied. The soft palate and swallowing reflexes were weak. Disturbance of ocular movement to the right, on the left occasionally Babinski's reflex. The disturbance in walking was increasing, so that at times he could scarcely stand. Although no cerebral symptoms were present and the fundus oculi showed no changes, during the last few days a severe pain had come on over the sacrum that had made the child cry out; there was also at times a marked stiffening of the spinal column, but no stiffness of the neck. The speaker believed there was disease of the cerebellum and bulb. Considering the rapid advance in the symptoms it was most probably a new growth. There was no trace of syphilis or tuberculosis except for a slight rise of temperature, which had made its appearance only during the last few days. Both age and the rapid progress were not in favour of any sclerotic process or multiple sclerosis in the regions of the pons. Most probably there was an infiltrating new growth. Possibly the sacral pain and stiffness in the spinal column indicated extension to the spinal meninges; it might be a diffuse sarcomatosis.

At the Urologische Gesellschaft, Hr. I. Israel made a communication regarding

OPERATIONS FOR URETERAL CALCULI.

The number of operations for calculi of the ureter was small, but this was owing to failure in diagnosis. Formerly a diagnosis could only be made when the stone was palpable, whilst now it was rendered easy by radiography. He himself had now operated in 58 cases. These calculi passed down from the kidneys, lodged in the ureter, and there grew larger through deposition of salts. There were, however, autochthonous calculi developed through some change in the wall of the ureter. Stones were most frequently met with in the small pelvis, and amongst them the interparietal were the most frequent. Palpation was only possible occasionally. In some of the cases the Röntgen plate did not reveal the stone; this was so in 11 per cent. of the cases. There might be insufficiency in the plate with anuria; there were also shadows on the plate which might be taken for calculi, also specks in the pelvis and coprolites; calcified glands might also simulate stones. In 18 per cent. of the speaker's cases the calculi were on both sides. Amongst the cases that were not radiographed two died, amongst those that were, not one—a proof of the importance of radiography. The indications for operation were anuria lasting for 48 hours, bilateral calculosis, retention and infection of the kidney of the affected side. If a stone was so large that there was no hope that it could be passed, then one must operate. Another

indication was a fixed pain in the ureter. For operation an extra-peritoneal one was technically the best. Where the stone was deep-seated exact suture was difficult. If one could slip the stone upwards it was a help, but it should only be done if it could with ease. Ureterotomy was the normal procedure. It was insufficient in pyonephrosis, extensive exudations and abscesses. Here nephrectomy was called for. In some cases removal of the ureter was demanded. The mortality had not been great when the infected cases had been separated from the local ones. In 25 extra-peritoneal operations there had been no deaths. The total mortality of his cases had been 4 per cent. The results of extra-peritoneal operations had been absolutely ideal.

AUSTRIA.

Vienna, Sept. 21st, 1912.

"KUBITAL" GLAND AND SYPHILIS.

GOLDREICH told his clinical hearers not to be led astray by the usual assertion that these glands in the infant and young child were pathognomonic of hereditary syphilis. They were not, but he would not deny they were associated with the disease as they were an outlet for the toxine. He had carefully examined 212 cases of undeniable congenital syphilis and found that these glands were not a trustworthy guide in the diagnosis as this sign was frequently absent, but in the same number of perfectly healthy children, 17 per cent. of infants and 21 per cent. of children had the glands affected. The glands are so frequently swollen in syphilis that the error of an undeniable symptom has been attached to the stigmata.

SPURIOUS VACCINE.

Paul, Director of the State Vaccine Institution, raised an important discussion at the Congress of Medical Officers of Health. He reported two cases as an example of numerous others where the vaccinia, or supposed vaccinia, had been transmitted from one cow to another as well as the attendant. It was even suggested that the use of the milk had produced an outbreak of cow-pox. In the cows affected the veterinary surgeon had pronounced the affected cows as suffering from cow-pox which had purulent pustules on the udders. On testing the serum biologically by vaccinating the cornea of guinea-pigs, the effect was negative. The bacteriological examination proved the presence of a pure streptococcus found in vaccine where the milk obtained from these cows also contained a virulent streptococcus. He thought a closer study of this abnormality should be made and some definite understanding of a hygienic character was absolutely necessary for the purveyors of milk.

BENEDICT'S SUGAR TEST.

This test has been under criticism recently and has received a large amount of praise for its simplicity and accuracy. The solution is made by adding 17.3 grammes of copper sulphate, 173.0 grs. of sodium citrate, 100 grammes of sodium carbonate free from water added to a litre of distilled water. Five centimetres of this solution are added to 8 or 10 drops of urine to be tested. After well shaking it is boiled for two minutes, then gradually cooled. If sugar be present a red, yellowish or greenish precipitate is formed, even when only three-tenths per cent. is present. If no sugar, the solution remains clear or retains a light blue cloudy appearance from the urates. The quantitative determination is a simple modification of the qualitative, which is performed by adding potassium sulpho-cyanate to the quantitative solution, when, in consequence of the reduction that takes place, a white copper sulpho-cyanate is formed, so that the final titration can be observed. This method of determining the amount of sugar is claimed to be much superior to Fehling's or Purdy's method in simplicity and exactness. For clinical purposes it is much superior to Lohstein's fermenting method, which occupies a considerable time, while the results with Benedict's solution can be found exactly in five minutes. It has also an advantage over the polarisation method that expensive instruments are not

required, and no mistakes arise from other substances producing left rotation. The solution is also stable, and Benedict recommends for volumetric purposes 18.0 grammes of copper sulphate, 100 grammes of water-free sodium carbonate, 200.0 grammes of sodium or potassium citrate, 125.0 potassium sulpho-cyanate, and 5 cubic centimetres of a 5 per cent. potassium ferrocyanate in a litre of distilled water.

HUNGARY.

Budapest, Sept. 21st, 1912.

THE ACTINIC TREATMENT OF TRACHOMA.

DR. WALDMANN investigated the basis of success obtained and described by Cohn, of Breslau, with radium in the treatment of trachoma. Waldmann has, in fact, found a theoretical basis for the explanation of the success, inasmuch as it is assured by several investigators that the beneficial effect of radium on malignant growths is due to its power to decompose the lecithin which forms a substantial element of these growths. As the granulations of trachoma also contain a certain percentage of this substance, the effect thereon of radium becomes intelligible. The author picked out seven trachomatous cases of a most pronounced character. The amount of radium used was at first 1 mg., and later 10 mg.; time of exposure five to ten minutes. The tube containing the radium was simply applied over the area treated, and slowly moved about without touching the surface. The results were really astonishing. Five of the seven eyes were entirely cured; the other two are in a fair way of becoming so. The absorption of the granules was not accompanied by any untoward effect. The number of sittings varied from eight to fourteen.

ARTERIO-SCLEROSIS AND IODINE.

Dr. Veress said at the recent meeting of the Budapest Royal Society of Medicine that although the use of this drug in the treatment of this condition is very extensive, yet but little is known of its mode of action. He presented the results of a series of observations in young men, otherwise healthy, to whom potassium iodide was administered in daily doses of from 0.3 to 0.5 gr. for periods of ten to fourteen days. It has been claimed that this drug has no vaso-dilating action. Examination of the blood from the experimental subjects showed that there was a marked loss of viscosity, sometimes as much as 10 per cent. This apparently explains most of the therapeutic effects of the drug, as its action, increasing the fluid character of the blood, is equivalent to dilatation of the vessels, for the reason that the stream flows more rapidly. This also shows that the drug must be continued for long periods in order to produce any effects. The serum does not become fluid to the same degree as the blood *en masse*, and sometimes is even increased in density, so that the change appears to be governed by the behaviour of the cellular elements of the blood alone.

UNCOMMON FORMS OF RHEUMATISM.

Dr. Kunitz made some interesting comments on this subject. He believes that a sharp line must be drawn between muscular and joint rheumatism: To secure uniformity and to avoid confusion, the term muscular rheumatism ought to be dropped, and the word rheumatism applied to that inflammatory condition of the various locomotive organs and their appendages which results from sudden changes of temperature. Persons inclined to rheumatism need not therefore fear intense uniform cold, but rather over-heating, especially that brought about by muscular exertion, followed by sudden rest and cooling. The quickest and most reliable remedy in cases of fresh or acute rheumatism is exercise. The patient may safely indulge in all these movements which cause pain, but care should be taken to exclude joint rheumatism. Chronic rheumatism can only be cured by mechano-therapy, in which active and passive movements play an important part. Among the rarer sites for rheumatism which are little mentioned in the literature are the following: A rheumatic process in the periosteum of the ribs, the sternum, and localised rheumatism of the muscles of mastication. Instances of these are described where good results were secured in all but that of the

diaphragm by forcible massage. For rheumatism of the diaphragm the Faradic current gave some relief.

CANADA.

Montreal, Sept. 16th, 1912.

ANNUAL MEETING OF THE CANADIAN MEDICAL ASSOCIATION, HELD AT EDMONTON, ALBERTA.

THE North-West of Canada has been honoured as the meeting-place of the Canadian Medical Association only once before. Twenty-two years ago the meeting was held at Banff. In 1904, however, Vancouver, on the Pacific coast, was chosen as the place of meeting. The meeting which took place this year at Edmonton was eminently successful. In spite of the distance to be travelled to reach Edmonton from the eastern part of Canada, no fewer than 500 medical men were present. Doubtless many of them took advantage of the meeting to combine, to some extent, business with pleasure and to view the wonderful country abutting on the Rockies and to take note of the progress made therein. Dr. Herbert A. MacKidd, the President, as might be expected from a Westerner, delivered a stirring presidential address. Perhaps the most important part of the address was that in which he referred to the proposed creation of a

NATIONAL DEPARTMENT OF PUBLIC HEALTH.

At the Vancouver meeting in 1904 this matter was first mooted. Again, at the first meeting of the Canadian Public Health Association, held last December in Montreal, under the presidency of Professor Starkey, of McGill University, Premier Borden promised that the Government would institute a general reform in public health matters, and place that department on a sound and modern footing. Dr. MacKidd voiced the hope that the question would be soon settled, and later on a unanimous vote was passed by the medical men present in favour of the establishment of a Federal Department of Public Health. Reference was also made to Dominion legislation which had come to pass during the past few months solely through the efforts of Dr. Roddick. The passage of the "Roddick Bill" had rendered interprovincial medical reciprocity possible, and the Bill would go down in history as a monument to Dr. Roddick. The speaker paid, too, a well-deserved tribute to Dr. Macphail, of Montreal, for his able editorship of the *Journal of the Canadian Medical Association*, which came into being two years ago. Already the *Journal* has done much towards organising and welding together the profession in Canada. Dr. MacKidd, in conclusion, eulogised the North-West, and predicted for the medical profession therein a most rosy future.

THE ADDRESS IN SURGERY

was given by Dr. Arthur E. Giles, of the Chelsea Hospital for Women, London. The address was remarkably good, and was a justification of operative measures, especially in the case of inflammatory disease of the uterine appendages. It was pointed out that as long as the operative mortality was high such patients could not be advised to undergo surgical treatment. But now, when, as the figures of the Chelsea Hospital for Women show, the death-rate is as low as 1.3 per cent., an operation of this kind is amply justified. Dr. Giles said that two years ago he was able to show, from a detailed investigation of the after-results of these operations, based on 200 cases in which both ovaries had been removed, that 70 per cent. of the patients regained perfect health and vigour and retained their sex instincts.

With regard to fibroids, Dr. Giles said that when a patient with fibroids had to be told that the resources of medicine were exhausted, and that the succour of surgery was more cruel than kind, it was a great comfort to be able to hold out some kind of hope, however unsubstantial; and so a fairy tale was built up and decorated to represent a scientific theory, to the effect that the menopause was the natural cure for fibroids. And patients were told in all seriousness and good faith, "You must wait for the change of life, and then these tumours will shrink and disappear and you will get well." And the patients went on patiently draining their life blood away, carrying enormous

tumours that prevented them from getting about, hoping against hope that the delayed menopause would arrive like some millennium to give them peace. Some of them were spared the worst troubles and escaped with their lives, a few of them regained a measure of health, and the remainder became more or less permanent invalids. Others found that the menopause, when it came, came not to bless but to curse, bringing in its train degenerative changes, infection, sepsis and death. Dr. Giles therefore records as his emphatic opinion that, considering the very small rate of mortality from hysterectomy for fibroids at the Chelsea Hospital for Women, he is justified in the contention that all fibroids should be operated upon, unless some weighty reason to the contrary can be shown, in the early stages, as soon as symptoms arise and without waiting for the development of grave complications; and that whereas in the early days hysterectomy had to be reserved in cases in which it was required for the saving of life, the progress of abdominal surgery had brought it within the scope of operations that are justifiably performed for the relief of suffering and the restoration of health.

(To be continued.)

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

BELFAST.

HOSPITAL ABUSE.—A series of resolutions on the subject of hospital abuse, which were passed at a meeting of the Belfast Medical Guild on September 5th, have been circulated to members of the staffs of the Belfast hospitals, with a suggestion that a joint meeting of the various staffs should be held to consider them. The resolutions are to the effect (1) that no certificates should be given in hospital, except in medico-legal cases, when a guinea fee should be charged; (2) that no patient should be given attendance at any hospital, except in cases of emergency, without a line from the ordinary medical attendant; (3) that no prescription should be given to an intern patient when leaving hospital, but if necessary the patient should be advised to see his ordinary medical attendant. The second of these resolutions is undoubtedly the most revolutionary, and it is hard to see how it can be made to work. Even now a large number of hospital consultants write to medical men whose cases they have seen at hospital, if such cases happen to be specially serious or difficult, and it is the common complaint that the majority of such letters are never answered. The plan suggested would certainly reduce the numbers in the hospital externs, but whether it would meet with the approval of the public which supports the hospitals, or even with that of the busy general practitioner when he came to try it, is more than doubtful.

SANITARY CONDITION OF PORTADOWN.—At a meeting of the Portadown Town Council held last week, a warm discussion took place on a report from Dr. Rowlett, their energetic Medical Officer of Health. He recommended the demolition of 196 houses, accommodating nearly 1,000 persons, on the ground that they were so defective that it was impossible to remedy them, and that such defects are the cause of, or at any rate aid in spreading, epidemic disease. Naturally the Council was not prepared to accept the recommendations off-hand, seeing that, as one member said, there would be very little of their town left if they did so; but the tone of the discussion was on the whole good, and showed a most satisfactory respect for Dr. Rowlett's opinion. The matter has been referred to the Sanitary Committee for investigation.

LORD KELVIN MEMORIAL.—Many old students of Queen's College, Belfast, will be interested to learn that a statue of Lord Kelvin is to be erected close to the University, in the grounds of the Botanic Gardens Park. The site chosen is close to the main entrance of the Gardens, in full view of the Malone Road. It was suggested at one time that it should be placed in the grounds of the University, but as it is being erected

by public subscription, under the auspices of the Lord Mayor, there was some difficulty in placing it in any ground not under the control of the town.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE POSITION OF DENTISTRY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I notice that in the current issue of the "Medical Press and Circular" considerable space is devoted to the problem of dental practice in this country. One of your correspondents, who signed himself "A Hospital Dentist," makes a virulent attack on all unregistered men. I venture to think that it would be more statesmanlike to recognise at the outset that the practice of medicine and the practice of dentistry cannot be judged by the same criterion. Permit me to tabulate the bare facts.

(1) A very large number of unregistered dental practitioners conduct their practices in a thoroughly ethical fashion.

(2) A large, though a decreasing, proportion of registered men (qualified by examination) have no better qualification to practise than the foregoing unregistered class, and some who are on the dental register and who are legally protected are druggists, etc., who know little or nothing about dentistry.

(3) A large proportion of dentistry, of the poorer class especially, consists in extractions and purely mechanical work, and many unregistered men are actually more skilled in this respect than men who have qualified by examination, but who have not one-tenth the experience in many cases of the unregistered.

(4) The number of qualified men is not nearly sufficient to supply the dental requirements of the nation, and the suppression of the unregistered men would mean either that the lower middle class and the working class public would go without any dental attendance, or there would have to be established a huge public dental service, rate aided or State supported.

(5) Your readers must bear in mind that a medical practitioner whose practice lies chiefly amongst the working class can, in the great majority of cases, see a relatively large number of patients in a short space of time; but conservative dentistry by a highly qualified dentist cannot be speeded up; hence, the qualified dentist cannot work at the same rate per head amongst the working class as the qualified medical practitioner.

On the other hand, it is practically true that a large number of ignorant and unscrupulous quacks are inflicting an immense amount of injury upon the poorer class. I attribute this unhesitatingly to a large extent to the puffed-up narrow-mindedness of the leaders of dentistry in the past, who were far too anxious to secure social status at least equal to their medical colleagues, rather than to secure dental legislation and administration responding to the national needs. Many of them are still engaged in the useful occupation of seeking oblivion from the facts. There are certainly not less than 25,000 on the list of unregistered dental practitioners in the United Kingdom, as against some 3,000 qualified men. Do you imagine that Parliament will ever consent to take the livelihood from these unregistered men? It is crying for the moon. A regulating Act by all means, but you will never succeed in suppressing the existing unregistered practitioners.

Trusting that you will find space for this protest and explanation,

I am, Sir, yours truly,

AN INTERESTED OBSERVER.

London, September 23rd, 1912.

PARSIMONY IN HOSPITAL MATTERS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your attention has been doubtless directed to an incident recorded of a great Midland hospital, in

which a physician was adversely criticised for having ordered strawberries in the month of March to a hospital patient. To make the story complete, it should be added that the strawberries cost 7s. 6d. a basket, and the patient was suffering from "sprue," a disease for which the fruit in question has been recommended by an eminent medical authority on tropical diseases. The insinuation of the critic was that such an expenditure and such a prescription were unjustifiable. If there were any prospect of cure by strawberries, was such an outlay justifiable in view of the funds of the hospital, the needs of the particular case, and the necessities of the rest of the hospital patients? So far as the funds are concerned, a few such patients—for each would require a course of seven and sixpenny baskets—might well cause the authorities of the wealthiest voluntary charity to look askance. We may at once admit that a physician is not bound to consider the cost of remedies he considers essential to the real interest of his patient. But can sprue be cured by strawberries? We doubt if any such effect has ever been recorded, and all who have had to do with that distressing complaint will bear testimony as to its stubborn and refractory nature in spite of every available remedy. What about the rest of the patients and their daily needs of routine medicine and board? It is tolerably clear that in order to treat certain patients in the costly fashion indicated, others must run short.

In many ways the matter raised by Mr. Danvers Power is most interesting; and as the principle involved is one of great interest to the medical profession, I trust some of your numerous readers will favour us with their views upon the subject.

I am, Sir, yours truly,
A FRUIT LOVER.

Belfast, September 23rd, 1912.

SPECIAL REPORTS.

THE KING EDWARD VII. SANATORIUM.

THE fifth annual report of the King Edward VII. Sanatorium (July, 1910—July, 1911) declares that during the year all the beds in the sanatorium have been continuously occupied. During this period 271 patients were discharged. There is the usual complaint common to all sanatorium reports that too many patients in advanced stages of consumption find their way into the institution. Of the cases discharged during the year only 33.5 per cent. could be classed as "early cases" at the date of their admission. No less than 16 per cent. were in an advanced stage.

The treatment, as administered in the sanatorium, is of a conservative type. Tuberculin is only given to a few selected cases, but we gain no information as to the principles which guide the selection. In twenty cases attempts were made to treat secondary infections by suitable vaccines, but in only one were the results satisfactory. Care is taken to provide occupation as far as possible for the patients in lieu of walking exercise.

The results of treatment are tabulated in statistical form. Of 91 cases of "slight severity" the disease was arrested in 54.9 per cent., 34.1 per cent. were much improved, 4.4 were improved, and 6.6 remained stationary. Of 115 cases of moderate severity, the disease was arrested in 12.2 per cent., 51.3 per cent. were much improved, 12.2 per cent. were improved, 19.1 per cent. remained stationary, and 5.2 per cent. became worse. Of 44 cases of advanced disease, 20.5 per cent. were much improved, 35.4 per cent. were improved, 22.7 per cent. remained stationary, 15.9 per cent. became worse, and 4.5 per cent. died.

With regard to the after-history of patients, the report draws attention to the difficulties met on account of the growing fear of infection among the public. "A free opening of windows is enough to excite suspicion." It is important that no instance has come to the notice of the staff of a member of the

family of a former patient having become consumptive. It is of interest to note that the patients who do best after leaving the sanatorium are clergy and medical men. This is probably because members of these professions can, more readily than others, find occupation in suitable surroundings.

Dr. Radcliffe, Pathologist to the Sanatorium, adds some interesting notes on his work. He has found the Ellermann-Erlandsen method of help in searching for tubercle bacilli in sputum, and he believes it greatly superior to the vaunted antiformin method.

THE BRITISH HOSPITALS ASSOCIATION CONFERENCE.

THE third annual conference of the British Hospitals Association was opened at Birmingham last week. Mr. J. B. Clarke, Chairman of the Board of Management of the Birmingham General Hospital, presided, and representatives were present from all the principal centres in the country.

The Lord Mayor (Alderman Bowater) welcomed the visitors, and said, with reference to the Insurance Act, that he supposed the action the hospitals would take would depend on the particular policy that the doctors adopted. He was not going into the matter except to say that he wished the Government would realise that there was a very strong public opinion in favour of doctors being well paid.

Dr. Nathan Raw, Physician and Medical Superintendent, Mill Road Infirmary, Liverpool, read a paper on "The Probable Effect of the Insurance Act upon Voluntary Hospitals and Other Institutions." He estimated that when the Insurance Act was in full swing 30,000 beds would be required to deal with the illnesses of 15,000,000 insured persons. In his opinion, in the course of a few years, when the funds had accumulated, the Insurance Committees would provide their own hospitals for the sole use of insured persons, with a properly paid professional staff, on the lines on which many of the German hospitals were conducted and which worked so smoothly. Of various courses open to the voluntary hospitals, Dr. Raw preferred that by which they would cease to be voluntary institutions and have a fixed scale of charges—first, second and third class, the beds to be open to all citizens (the insured persons would be third class and pay something like 2s. 6d. per day).

Dr. T. Basil Rhodes, Secretary and House-Governor of the North Staffordshire Infirmary, who also submitted a paper dealing with the effect of the Insurance Act upon voluntary hospitals, said it had been suggested that the hospitals should at once announce that they would not treat insured persons except in cases of emergency. That step seemed to him both unnecessary and suicidal—suicidal because the subscriptions from working men would cease at once; and unnecessary because the medical profession and the hospitals' committees could together make such arrangements as would allow of the treatment of insured persons under certain agreed conditions. He suggested that at the end of the financial year every hospital should be examined by a State inspector on certain points touching expenditure and management, and if the report were satisfactory should receive from the State the amount by which the expenditure for the year had exceeded the income.

In the evening the Lord Mayor gave a reception in the Council House.

Among other interesting papers read was that by Mr. J. Danvers Power, member of the Council of King Edward's Hospital Fund, on "Hospital Management Considered with Reference to Responsibility." He contended that hospital "scandals" would scarcely ever be heard of if responsibility were properly allocated at the outset. Committees were frequently blamed for what they had no real power to prevent. A case in point was the admission of patients. In one of the London hospitals a surgeon with twenty beds had, in the first eight months of the present year, sent in 74 patients by his personal request; they came straight in, others had to take their turn afterwards. He did not criticise this, beyond saying that the respon-

sibility should rest on the surgeon. With regard to divided responsibility, Mr. Power referred to the work of the staff and the lay committee, and said that about professional work there should be no question. At the same time there were cases where a committee responsible for expenditure refused to carry out the orders of a single doctor. A secretary had written to him that, a physician having ordered in March strawberries at 7s. 6d. a pound for a patient, he refused to supply them. The patient was suffering from some obscure West African disease, and the physician took the matter to the committee, who supported the secretary. Mr. Power said that in such a case the position of the committee was unsatisfactory, and he himself did not see any half-way house between ceasing to admit certain classes of cases altogether and leaving disputed points about treatment to the final decision of the staff. There should be no two kinds of responsibility attached to one class of hospital business. Similarly, if a central collecting fund prohibited the applying of its grant to medical education, the responsibility for misapplication of the money should rest on the treasurer of the hospital. If he were attacked from outside then an impartial inquiry should be held and the attack should be substantiated. Any other course would be certain to lead to more or less damaging criticism, because there would be a faulty distribution of responsibility. He was very strongly opposed to official interference with local management, but if advice must be given by central authority, at least let it be accompanied by responsibility. Then at any rate it gave all the guarantee in its power.

Mr. A. W. West, Chairman and Treasurer of St. George's Hospital, London, in opening the discussion, said he remembered the case of a hospital in which it was considered that the amount of spirits consumed was excessive. Three monthly returns showing clearly the amount ordered by each physician and surgeon were made out and circulated among the staff. The amount of spirits ordered was reduced by one-half very quickly, because the responsibility was placed on those ordering it to justify their action. There was still further room for improvement in the system of hospital accounts.

Mr. Gilbert Barling, Senior Honorary Surgeon, Birmingham General Hospital, remarked that if they were to be starved in the matter of scientific developments, he would rather see the voluntary system pass away and be replaced by a municipal hospital system—not by a Poor-law hospital system. Hospital treatment was bound to be more and more expensive as it was more specialised. For instance, fifteen years ago they knew nothing of radiography; to-day it was costing the Birmingham General Hospital several hundred pounds a year, and there was value for it in the service of the hospital.

Mr. Montague Browne, Northampton General Hospital, thought that if the voluntary hospital lived they would have in many matters to put their house in order or somebody else would put it in order for them.

REVIEWS OF BOOKS.

SYPHILOLOGY. (a)

MUCH work has been done in connection with the pathology and treatment of syphilis and venereal disease since the first edition of this book was published. The author has succeeded in producing a compact and comprehensive treatise on these important subjects which contains all that the practitioner or student is likely to want. Methods of obtaining the spirochaetes and of mounting and staining them are well described, and a good account is given of the serum diagnosis of syphilis, as well as the interpretation of the results of the Wassermann test. Whether the "syphiline" test, as experimented with by Fontana with the object of producing a cutaneous reaction, is likely to be as useful as the Wassermann reaction, time alone will prove. The merits and drawbacks of

salvarsan are well discussed, but it may be noted that the author is of the opinion that "the great majority of cases of syphilis can be cured with mercury and iodides." A useful list of substances, with their strengths, suitable for injection in gonorrhoea is given at the end of the book. The chapter on syphilis in relation to life assurance and marriage is an important one. Blaschko's advice is quoted to the effect that, upon the average, a life may be accepted four or five years after the onset of the disease, in the absence of symptoms. With regard to marriage, Dr. Marshall considers that an arbitrary time-limit is both dangerous and unscientific, and that the duty of the medical man lies in explaining the whole situation carefully to his patient. The book is excellently got up and is pleasant to read.

SKIN DISEASES. (a)

IN "Golden Rules of Skin Practice" Dr. David Walsh has succeeded in compressing within a very small space a vast amount of information indispensable to the student of dermatology. This concise little manual has now reached its fourth edition and it has been brought fully up to date. It is just the book for a student or practitioner to keep in his pocket while he is "taking up skins," for its pages abound in terse little aphorisms, easily learned and remembered, so that the main facts relative to the diagnosis and treatment of a given case can be readily assimilated.

Believing that the treatment of dermatological cases can be studied more or less as a thing apart from diagnosis and pathology, Dr. W. Knowsley Sibley has endeavoured in his "Treatment of Diseases of the Skin" (b) to produce a manual of reference for the use of dermatologists, practitioners and students, embodying the various treatments employed for the ordinary, and some of the rarer, diseases of the skin, which are ranged in alphabetical order. The more modern methods of dermatological therapeutics are dealt with in a concise but intelligible fashion, such as cataphoresis, high-frequency currents, vaccines, electrolysis, Bier's hyperæmia, solid carbon dioxide, etc. We had expected to see more than half a page devoted to the administration of salvarsan in syphilis, whereas nine pages are occupied with a description of the various methods of giving mercury and the iodides. While acknowledging the value of X-rays in the treatment of ringworm of the scalp, of which a good account is given, the author states that "the most scientific way for the drug treatment of ringworm and allied affections should be by a process of cataphoresis, by means of which the drug used is actually driven into the deeper tissues of the skin, largely through the hair follicles, and so in this way must be applied to the seat of the disease." This is very true, although we object to the word "cataphoresed."

The omission of any account of liquid air, the dismissal of radium in one line, and the disproportionate amount of space devoted to Bier's hyperæmic method (twenty-five pages), may, presumably, be accounted for by the author's special experience with the latter treatment. We do not find any reference to the newer cell-proliferants which have been found of service in the treatment of the various forms of ulceration. The treatment of lupus vulgaris is fully described, and we notice that Dr. Sibley has obtained good results by the use of the solid carbon dioxide, though, curiously, there is no mention of this agent in the treatment of lupus erythematosus, in which it gives equally good, if not better, results. The author has found the plan of dissolving the snow in ether or alcohol useful for painting upon cutaneous lesions where a continuous application without pressure is desired. It is easy, however, to be hypercritical in dealing with a work of this kind, and we are of the opinion that this book, in spite of the defects we have indicated, will prove a useful and serviceable companion to the dermatologist and prac-

itioner alike. There are several excellent photographic illustrations and a good formulary of baths, lotions, etc., at the end of the book.

PATHOLOGY. (a)

THE third edition of this excellent work will be welcomed by all interested in pathology, whether as students or as medical practitioners. The peculiar charm of the book lies in its condensation, whereby the matter is restricted on the one hand to simple statements of fact, and on the other to a lucid summary of existing theories. In spite of the advances of pathology during the past generation one is constantly reminded in a work of this kind of the many gaps in our knowledge. Little is known, for instance, about xanthoma, with its peculiar site of election, and we are informed simply that it is a "yellowish neoplasm occurring about the eyelids, and, structurally, in an embryonic adipose tissue." No hint is given as to its possible microbial origin or degenerative significance, perhaps because of the lack of trustworthy information upon these points. Nor, probably for similar reasons, do we find amongst the non-malignant growths any mention of the interesting group recently described under the title of multiple benign epithelioma of the skin. If we turn to the field of positive knowledge, we find little room for criticism. The subject of gout, for instance, is dealt with in a clear and comprehensive way, and no important theory or observation is excluded. With regard to the uric acid dyscrasia we are told that:—"A disorder or group of disorders is associated with the excessive formation of uric acid. One of the chief of them is gout or podagra; migraine and neuralgias also often seem to be dependent on the same cause, while Haig and others, it can hardly be doubted, have exaggerated the importance of uric acid, and have ascribed all sorts of disorders to its presence in the body, a condition which has been termed "*uricacidemia*, or the uric acid diathesis." An interesting account is given of the present stage of our knowledge and theory with regard to malignancy. The following note is made of changes that have a practical application in the diagnosis of doubtful cases. "Blood," it is observed on p. 85, "normally has a certain degree of anti-tryptic action, in cases of carcinoma and sarcoma this power of inhibiting trypsin is increased to double the normal or more. Mackenzie and Rosenheim have also shown that the lipolytic power of the serum is likewise increased in cancer cases." Again (p. 258), it is said: "A combined increase in the anti-tryptic power and in the lipoclastic accelerating action of the serum is highly suggestive of malignant disease." In a notice such as the present, however, it is impossible to give more than a general outline of a book that covers so much ground, and this may be conveyed by the statement that it forms a concise, accurate and readable guide to a subject of growing practical importance to medical men in every branch of practice. The text is associated with a large number of illustrations, of which the numerous micro-photographs will be found most helpful. The book can be recommended to students and practitioners as one of the best practical text-books on the subject in the English language.

SEXUAL HYGIENE.

THE question has often been discussed as to what degree of information, if any, should be imparted to the youth of both sexes upon sexual matters. Some purists have adopted the ostrich-like policy of deliberately ignoring the plain facts, preferring, apparently, that the rising generation should acquire this knowledge by clandestine means rather than that they should be enlightened by wise and helpful counsellors. If parents, guardians and teachers will not recognise their responsibility towards their young charges in this direction they have only themselves

to thank when bad habits have been formed and lives ruined. The knowledge of the elementary hygiene and physiology of the reproductive system is quite as important as that of the digestive organs, and ignorance of the natural functions of the former may lead to results far more disastrous than in the case of the latter. The cry of many a blasted soul and ruined body to-day is: "If I had only known; if only someone had told me!" The difficulty lies in the selection of the methods by which timely information may be given at the critical period of puberty. There are certain drawbacks connected with the systematic class-teaching of sexual matters in schools and colleges, though there is much to be said in favour of the holding of small classes or "talks" upon the subject, preferably by a practical and sympathetic physician of either sex. There have been books written with the idea of educating the growing child regarding these matters, but the majority of them have been mawkish, too technical, or even bordering upon the offensive. We welcome, therefore, the series of small manuals in which the right note has been struck at last by Dr. E. B. Lowry (*a*). *False Modesty* deals plainly but simply with the results of ignorance of the functions of the reproductive organs in both sexes. *Herself* is a little larger book treating of womanhood in all its aspects from the physiological standpoint, suitable for young women and elder girls. *Confidences* treats in an elementary fashion of the phenomena of growth and reproduction, couched in simple language, and designed for placing in the hands of a girl from ten to fourteen years of age. In *Truths*, similar facts are presented for the instruction of boys. Each of these books may be safely taken by parents as a guide to help them in protecting their sons and daughters and in educating them upon the all-important subject of sex hygiene.

In the fourth edition of Dr. Veeki's monograph (*b*) every variety and form of *impotentia coeundi et generandi* is fully dealt with, and the author has endeavoured to reflect the gains introduced by urology. The chapters on anatomy and physiology have also, more especially in their relations to the modern conception of sexual neurasthenia, been revised. Dr. Albert Abrams contributes a short report upon the treatment of impotence by Freud's method of psycho-analysis. This book still retains its premier position in works dealing with this subject.

PRESCRIBER'S FORMULARY AND INDEX. (c)

THE compression of much material within a limited space appeals to many individuals, and it is to these that we can heartily recommend this little pocket book. Its size is tiny ($3\frac{1}{4}$ in. by $4\frac{1}{4}$ in.), but within its pages will be found considerable useful information which the busy practitioner is likely to need when writing a prescription, and since it includes only those drugs which the pharmacist can readily supply any feeling of uncertainty is eliminated.

The book is divided into four parts—(a) Internal Treatment; (b) Regional Remedies, including dental, nose, throat, and ear, eye, genito-urinary and rectal; (c) External Treatment; and (d) Synthetic Preparations. Scattered throughout are definite prescriptions which the author has found to be of value in the conditions indicated, and these make the work of additional utility. A *lapsus calami* appears on p. 40, the plural of "hanstus" being given as "hausti." This error, however, will readily be corrected by the intelligent reader. While the book is hardly intended for the medical man who relies on the modern proprietary remedies, and who is unable to combine drugs in the form of a satisfactory prescription, yet, for him who has this requisite knowledge to hand, Mr. Beddoes is to be congratulated on producing a booklet which will render material assistance.

(a) Chicago: Forbes and Co. 1912.

(b) "Sexual Impotence." By Victor G. Veeki, M.D., Consulting Genito-Urinary Surgeon to the Mount Zion Hospital, San Francisco. Fourth Edition, enlarged. Pp. 394. Philadelphia and London: W. B. Saunders Co. 1912.

(c) "Prescriber's Formulary and Index to Pharmacy." By Thomas Pugh Beddoes, M.B., B.C.Camb., F.R.C.S.Eng. Pp. 132. London: Bailliere, Tindall and Cox. 1912. Price 2s. 6d. net.

(a) "Pathology, General and Special." By R. Tanner Hewlett, M.D., F.R.C.P., D.P.H., Professor of Bacteriology in the University of London, etc., etc. Third Edition. London: J. and A. Churchill. 1912.

SUMMARY OF RECENT MEDICAL LITERATURE ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

The Origin of Epithelial New Growths of the Ovary.—

Goodall (*Surg., Gyn. and Obs.*, xiv., 6) thinks that from a study of comparative embryology, histology and function, largely in the ovaries of cows, which closely resemble the human ovaries, numerous facts can be deduced and explained. It is common for human ovaries to contain quite a quantity of foetal rests, and the arrest of complete expunging of functionless tissue is always bilateral when present at all. The rete ovarii in the human occupies a different position relative to the ovary as compared with other vertebrates. In many cases it is removed from the stroma in the beginning of the hilum, but this situation is not proof of its parovarian origin. Goodall insists strongly upon the germinal origin of the rete ovarii and other structures, because it gives a new view as to the origin of tumours of the ovary. The reason why the ovary is more subject to new growths than the testicle is that the former contains so much that is not necessary to its economy, while the latter is a finished organ. Foetal rests are generally bilateral, which explains the common occurrence of bilateral malignant tumours. The varied structure of the new growths is considered another argument in favour of this mode of origin. The fact that many tumours contain cilia is answered by the fact that the cells of the rete ovarii are frequently ciliated, and that ciliated epithelium has been found on the surface of the ovary and in cavities opening on to the surface of the ovary. All the structures normally and occasionally to be found in the human ovary are of germinal origin except the supporting stroma. The author has come across no structure in the ovarian tissue that can be associated with parovarian rests. In women past 35 years of age a dipping of the germinal epithelium into deep crevices is nearly always found, and the more recent of these are invariably associated with almost completely resolved corpora lutea. "This is one type of acquired new growth. Inflammation gives rise to another. Germinal rests may also exist as a result of primitive clefts as found in lobulated foetal and child's ovaries. In no case has an indication been found of the origin of tumours from Graafian follicles. Cysts of the corpus luteum are secondary to either infection with abscess formation or liquefaction of a large hæmatoma of the corpus, and are mere retention cavities. There are two types of interstitial cells—the adult fibrous tissue, or supporting structure, and the small embryonic cell which is the parenchyma of the ovary. The ovary contains two secreting structures, the corpus luteum and the parenchyma cells. These latter are the true continued internal secretory structure of the ovary. The corpus luteum secretion may be the same, but is a special structure for the purpose of reproduction. Cancer has two elements in its production—the presence of congenital remains or acquired defects, and some general diathetic change which operates upon these structures. F.

An Operation for Retro-displacement of the Uterus.—

Willis (*Surg., Gyn. and Obs.*, xiv., 6) describes the operation as follows:—"Each round ligament is grasped 1½ to 2 inches from its origin at the uterine cornua, a linen thread is passed through one ligament, then through the fundus of the uterus on the anterior surface half an inch from the apex of the uterus, and then through the other round ligament. This suture is then tied, bringing the ligaments together. The suture is continued downwards, using the broad ligament instead of the round ligament for three or four stitches. The uterus is then left, and the broad ligament plicated to within half to three-quarter inches from the reflection of the peritoneum to the

bladder, and then the suture tied off. An interrupted suture is placed so as to secure the round ligament to the uterus half way between its original insertion and its new attachment." [NOTE.—This operation has been tried by the writer of this summary, and gives most excellent immediate results. It is very simple to perform, and has the advantage that there are no new bands or adhesions formed in the abdomen, and no perforation of the fasciæ of the abdominal wall other than the incision for laparotomy.] F.

Observations on Induction of Labour.—Broadhead.

(*Amer. Jnl. Obs.*, lxx., 5) says that for induction of labour with the modified Champetier de Ribes' bag, sizes two and three, are most useful. Accidental rupture of the membranes occurs in only 3 per cent. of all cases. In 90 per cent. labour was induced by the use of not more than two bags, and in 70 per cent. one bag was sufficient. Anæsthesia is usually unnecessary. In 37 per cent. labour starts at the time of introduction of the bag, and in 70 per cent. within 12 hours, the average length of time being eight hours in primiparæ, and ten hours in multiparæ. The cord presented or prolapsed in 4.3 per cent. The mortality in private work is practically nil and in hospital slight. F.

The Pathology of Epilepsy.—Clark (*Boston Med. and Surg. Journ.*, July 18th, 1912), examines for us in an interesting way the recent work which has been done in the study of epilepsy. Advance has mainly been made along two lines (1) the hereditary nature of the disease, and (2) the bearing which disorders of metabolism and perversion of the internal secretions of the ductless glands have on its pathology. Investigations concerning the hereditary transmission of idiopathic epilepsy have, according to Clark, not been at all so suggestive as have similar investigations concerning the transmission of feeble-mindedness. Clark contends that where the hereditary nature of the disease is admitted the prognosis is rather better than among other patients, and states that two-thirds of the recoveries among his patients occurred in patients where the disease was transmitted. The investigation into the toxæmic origin of epilepsy has not advanced far at present, but some advance has been made, and the experiments of Meyer and others seem to show that the toxic substance which is the direct cause of the fits is to be found in the blood serum. At one time it was supposed that this toxin was absorbed from the alimentary canal and was the result of faulty metabolism and elimination. That this is not the entire explanation is shown by the fact that "when the digestive apparatus has been put quite right, at least so far as one is able to judge, the great majority of epileptics, about eighty per cent., still continue at more or less regular intervals to have seizures." Clark concludes with the recommendation that "the sedative treatment of epilepsy is to be thoroughly discouraged so long as there is hope of bringing the real clinical pathogenesis of the disease under control." K.

Therapeutic Injections of Deep Sea Water.—Keck (*Pacific Med. Journal*, August, 1912), has for some time been in the habit of using the isotonic solutions of sea water recommended by Quinton of Paris, but he now finds that he gets better results by using the sea water in its full strength. The water used is obtained one thousand miles out at sea and at a depth of fifty feet below the surface. Such water is practically sterile and is on the average about five times as strong as normal salt solution. It is sterilised by exposure to

the ultra violet rays, and diluted till it is four times as strong as normal salt solution. As a rule 25 to 30 cc. of this solution are injected intramuscularly three times a week for two or three weeks. The quantity may be gradually increased till a feeling of fullness in the head and lassitude are produced. Keck finds that over-doses do no harm beyond causing needless fatigue, but too small a dose is of no value at all. The treatment has proved effective among patients suffering from a great variety of diseases, and can be carried out without the patient being confined to bed.

The Pathological Anatomy of Old Age.—Salimbecci and Géry (*Annales de l'Institut Pasteur*, August 25th, 1912) publish an interesting anatomical and pathological account of the body of an old woman of ninety-three years of age. All the organs and tissues were carefully studied. They found certain characteristic changes almost universal—viz., sclerosis, mono-nuclear and poly-nuclear infiltration, hypoplasia, cellular degenerations, and calcination. They believe that these are the principal processes of senescence in all organs. The most striking was the sclerosis, itself consequent on leucocytic infiltration. The hypoplasia was manifest in the glandular organs, though, on the other hand, the adrenals showed hyperplasia. The cellular lesions were less general, but were well marked in the liver and pancreas. Calcification chiefly affected the vessels. The observers agree with Metchnikoff that the absorption of intestinal poisons plays an important part in the production of the lesions of old age. It does not, however, stand alone. They enumerate four other groups of influences—(1) infection ascending to glands by their ducts; (2) the infinite series, in the course of a long life, of infective diseases and exogenous intoxications, each of which destroys its share of parenchyma; (3) wearing out and old age of the cells, apart from sclerosis and inflammation; (4) the loss of power of cellular reproduction. The article is illustrated by excellent plates.

R.

Anti-rabic Vaccinations at the Pasteur Institute.—Viala (*Annales de l'Institut Pasteur*, August 25th, 1912) gives figures for 1911 of the treatment undertaken for the prevention of rabies at the Pasteur Institute in Paris. Three hundred and forty-two persons were treated, of whom none died. This is the second year in succession in which the treatment proved successful in every case, a result never obtained previously. The number of cases treated continues to diminish. In 1910, 401 were treated, in 1907, 786, while the greatest number (2,770) was in the second year of the Institute, 1887. The highest mortality, both absolutely and per cent., was in the first year of the Institute, when there were 25 deaths, with a mortality of 0.94 per cent. Of the 342 persons treated last year, 76 had been bitten by animals in whom rabies was proved to exist, 114 by animals diagnosed as rabid by a veterinary surgeon, and 152 by animals suspected of rabies. We note that three patients from England were treated.

MEDICAL NEWS IN BRIEF.

Alcoholism and Insanity.

THE report of the Inspectors of Lunatics (Ireland) for the year ended December 31st, 1911, has recently been issued as a Blue Book [Cd.6386]. It states that the number of lunatics in asylums—24,655—shows an increase of 261 on the number for the previous year, when the corresponding increase was 250. But the increase for 1911 was 61 less than the average increase for the ten preceding years, which was 322. The number of insane under care has increased from 250 per 100,000 of the population in 1880 to 563 per 100,000 in 1911. The average rate of increase for the past five years was more than 5 per annum, whereas the average rate during the entire period was more than 10 per annum.

The number of insane resident in public asylums

(other than criminal) and workhouses about the beginning of the year under review was for the whole of Ireland 23,174, or 5.3 per 1,000 of the population; but the distribution is very unequal, varying from 2.6 per 1,000 in County Down to 9.2 in Waterford. The very large proportion of insane in County Waterford is exceedingly difficult to explain, but it appears that insanity tends to prevail in the agricultural and rural counties. The order of the four provinces is: Munster, 6.1 per 1,000; Leinster, 6.0; Connaught, 5.2; and Ulster, 4.2.

With regard to the question of "alcohol as a cause of insanity," the report states that the facts indicate that there is practically no relationship between the distribution of insanity and that of drunkenness in Ireland. Chronic alcoholism is so small in Ireland that it can have no great influence on the insanity rate.

The expenditure incurred in the maintenance of the average number of 20,112 patients in district asylums during the financial year ended March 31st was £587,597 11s.

University of London—King's College.

MORE accommodation has for some time been urgently needed in the departments of Bacteriology and Public Health. This has now been provided, with the sanction and approval of the University, by the removal of these departments, with their staffs, to 62 Chandos Street, Strand (Charing Cross Medical School Buildings), where an excellent suite of laboratories is at present vacant owing to the transference of the Charing Cross Medical School's preliminary and intermediate medical studies to King's College. The laboratories at Chandos Street are being altered and refitted, and the accommodation there provided will comprise a large class laboratory, research laboratory, professor's laboratory and lecturer's laboratory for each department of Bacteriology and Public Health respectively, a photo-micrographic laboratory, preparation and animal rooms, a large theatre, office and library for the joint use of the two departments. There will be the regular courses of instruction in bacteriology, clinical pathology, and photo-micrography, and for the Diploma of Public Health. Research and investigation work for public bodies and others will also be carried on as before. The new laboratories will be opened on or about October 1st. The laboratories vacated at King's College by this removal will be utilised for increasing the accommodation for the preliminary and intermediate medical studies.

The City of London Medical Officer.

THE salary of the City of London Medical Officer was brought to the notice of the City Council last week in the report of the Officers and Clerks Committee, which recommended that the salary be £800 per annum, rising £50 per annum at the discretion of the court to a maximum of £1,000. Mr. Hugh Shirreff thought that the position occupied by the City's Medical Officer, as the first in England, would be prejudiced if his salary were reduced from £1,000 to £800, which was what the Committee's report, if carried, would do. He moved that the commencing salary should be £1,000. This was seconded, and the matter was adjourned.

Gresham Lectures, 1912.

DR. F. M. SANDWICH, Gresham Professor of Physic, will deliver a course of four lectures on Tuesday, October 15th, and three following days, at the City of London School, Victoria Embankment, E.C. Each lecture will begin at six o'clock. The subject of the course will be the "Relief of the Sick and Wounded in Time of War."

Honour for a Woman X-Ray Victim.

Mlle. WEIDEMANN, the first woman to fall a victim in the cause of duty to the effects of X-rays, has just been decorated with the medal of honour by the French Minister of the Interior. While working in the laboratory of a Paris hospital her hands were attacked by X-ray dermatitis, and last year both her arms were amputated. This, however, did not arrest the disease, and little hope is now entertained of her recovery.

NOTICES TO CORRESPONDENTS, &c.

✎ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, 45; Half Page, 22 10s.; Quarter Page, 11 5s.; One-eighth, 12s. 6d. The following reductions are made for a series:—Whole Page, 13 insertions, at 43 10s.; 26 at 43 3s.; 52 insertions at 43, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8 Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

TO MEDICAL FREEMASONS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.
SIR,—May I, through the medium of your widely read columns, appeal to medical men, and medical Freemasons in particular, for votes for the Masonic charities.

At the forthcoming elections there are several medical candidates. Votes for any of the Masonic institutions are equally acceptable, as exchanges can be effected, and will be gratefully received and acknowledged by me.

I am, Sir, yours truly,

WILLIAM WILSON,

Secretary, St. Luke's Medical Lodge of Instruction,
184 Goldhawk Road, 1912.
September 17th, 1912.

A DAILY REGISTER FOR CONSUMPTIVES.

MESSRS. PARKE, DAVIS AND CO., have just introduced a neat and handy form of "Daily Register," prepared at the suggestion of Dr. de Carle Woodcock, of Leeds, for use by patients undergoing tuberculin treatment. Each page of the book records the progress made during the week, and full instructions are given to enable patients to fill in the required details themselves. The "Daily Register" is sent out in varnished envelopes, which keep clean, and are easily washable. The price is 6d. a copy.

Dr. W. P. F. (Parkeston).—We have not been able to trace the article to which you refer. One case of angio-neurotic oedema cured by salvarsan has, however, been described by Dr. C. W. Barr, of Philadelphia, in the *Journal of Nervous and Mental Disease*, Lancaster, July, XXXIX., No. 7.

OUT-PATIENT HUMOUR.

Speaking of Out-patient practice at St. Bartholomew's Hospital, the editor of the School Journal says:—"No day passes without its element of humour. One can go on rejoicing after dealing with the man who, when given a lin. sup. ticket with the injunction, "Rub your leg with this," goes behind the screen and literally massages his leg with it; and with him who, when asked the question one would ask of another suffering from a chronic hydrarthrosis of the knee-joint, replies, "No, sir, I don't smoke"; or with the old lady with a smart attack of scabies, who attributes her malady to a shock received in the train when coming home from Yarmouth last summer holidays."

THE CITY OF CARDIFF MENTAL HOSPITAL.

In the last annual report of the City of Cardiff Mental Hospital it is stated that the scheme for the provision of a laboratory for physiological research, by enlarging the pathological laboratory, has received the sanction of the Secretary of State, and that the work is about to be proceeded with by the building staff of the institution. When this is complete all the facilities of a modern mental hospital in touch with a University centre will be available for young medical men desirous of tuition and anxious to conduct research in mental diseases. The recovery rate, it is satisfactory to note, has been conspicuously low, being 60 per cent. for 1911, which has been a source of much gratification to the medical and the nursing staff.

Appointments.

COOMBS, HAROLD MARTIN McCULLOCH, M.B., B.C.Camb., L.R.C.P. Lond., M.R.C.S.Eng., House physician, Bedford County Hospital, Bedford.

FALCONER, A. W., M.D., Ch.B.Aberd., Assistant Physician to the Aberdeen Royal Infirmary.
FERGUSON, J. BELL, M.B., Ch.B.Edin., D.P.H.Manch., Chief Tuberculosis Officer for the City and County of York.
HEY, W. H., F.R.C.S.Eng., Honorary Surgeon to Ancients Hospital, Manchester.
MORLEY, JOHN, Ch.M.Manch., F.R.C.S.Eng., Honorary Surgeon to Ancients Hospital, Manchester.
PATRICK, J. KING, M.B., Ch.B., B.Sc.Glasg., D.P.H.Dub., Assistant Medical Officer of Health and Medical Officer in Charge of Tuberculosis Dispensary in the County Borough of Leicester.

Vacancies.

Royal Victoria Eye and Ear Hospital.—Two House Surgeons. Salary £40 per annum with board. Applications to the Hon. Secretary, Adelaide Road. (See advert.)
Buenos Ayres British Hospital.—Assistant Resident Medical Officer. Salary £200, rising £25 annually. First-class passage paid. Board and rooms in Hospital provided. Applications to Dr. Colbourne, Llanfair, Beckenham, Kent. (See advert.)
West Herts Hospital, Hemel Hempstead, Herts.—Resident Medical Officer. Salary £100 per annum, rooms, board, and washing found. Applications to Robert L. Butterfield, Clerk.
Dewsbury and District General Infirmary.—House Surgeon. Salary £100 per annum, with board, residence, and laundry. Applications to Edward Hemingway, Secretary.
Hampstead General and North-West London Hospital.—Casualty Officer. Salary £140 per annum, with board, residence, and laundry. Applications to A. E. Thomas, Secretary, Haverstock Hill, N.W.
County and City Asylum, Powick, Worcester.—Junior Assistant Medical Officer. Salary £160 per annum, with board, furnished apartments, washing, and attendance. Applications to Medical Superintendent.
Stirling District Asylum, Larbert.—Junior Assistant Medical Officer. Salary £140 per annum, with board, lodging, and laundry. Applications to the Medical Superintendent.
Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointment:—Kilmakyevoe (co. Kilkenny).
Royal Victoria Hospital, Folkestone.—House Surgeon. Salary £100 per annum, board, residence, and laundry found. Applications to the Secretary.
North Lonsdale Hospital, Barrow-in-Furness.—House Surgeon. Salary £100 per annum, with board and attendance. Applications to be sent Secretary, North Lonsdale Hospital, Barrow-in-Furness.
St. James' Infirmary of the Wandsworth Union, Ouseley Road, Upper Tooting, S.W.—Junior Assistant Medical Officer. Salary £120 a year, with board, lodging, and washing. Applications to the Medical Superintendent.
Tooting Bee Asylum.—Third Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

Births.

BOURKE.—On September 22nd, at 8, Moreton Gardens, South Kensington, the wife of Wm. H. Bourke, M.D., of a son.
DEANE-BUTCHER.—On September 20th, 1912, at Pittsworth, Queensland, Australia, to Dr. and Mrs. Bazett Deane-Butcher, a son.
EDELSTEN.—On September 14th, at 370, Brixton Road, S.W., the wife of Ernest A. Edelsten, M.B., M.A.Oxon, of a son.
HOWARD.—On September 19th, at Argyll House, Frome, the wife of C. R. Howard, M.D., of a son.
LEVY.—On September 18th, at 67, Wimpole Street, Cavendish Square, W., the wife of A. Harold Levy, F.R.C.S., of a son.
LONGSTAFF.—On September 18th, at Ridglands, Wimbledon, the wife of Dr. Tom George Longstaff, of 93, Whitehall Court, S.W., of a daughter.
PANCRIDGE.—On September 15th, at Winton House, Petersfield, the wife of W. P. Pancridge, M.B.Lond., of a daughter.
STOKES.—On September 19th, at The Laurels, Sutherland Avenue, Bexhill-on-Sea, to Dr. and Mrs. Kenneth Stokes, a son.
WALDO.—On September 22nd, at 40, Lansdowne Road, Holland Park, W., the wife of Frederick Joseph Waldo, M.D., Barrister-at-Law, of a daughter.
WORTON.—On September 16th, at Darley Dale, Hadley Wood, the wife of A. S. Worton, M.D., F.R.C.S., 71, Harley Street, W., of a son.

Marriages.

BAINES—RANSOME.—On September 11th, at the Mission Church, Lytton, British Columbia, Mark Blakiston Baines, M.B. Oxon, fifth son of Mr. and Mrs. Henry Baines, of Oxford, to Violet Grace, only daughter of Mr. and Mrs. Stafford Ransome, of 15, Redcliffe Square, South Kensington.
REEVES—DERRT.—On September 18th, at St. Matthew's Church, Upper Clapton, Conrad Reeves, M.R.C.S.Eng., L.R.C.P.Lond., of Alfriston, Sussex, third son of Mr. Herbert Reeves, late of Emsworth, Hants, to Hilda, the only daughter of Mr. and Mrs. Thomas Derry, Lynton House, Osbaldeston Road, Stamford Hill.

Deaths.

RANKIN.—On September 11th, at Bexhill, in his 63rd year, John E. Rankin, M.D., F.R.C.P., of Tunbridge Wells.

No. 14.

NOTES AND COMMENTS.

Police and Fortune-telling.

THE profession of fortune-telling by means of palmistry, astrology, crystal-gazing and the rest of the weird methods adopted by its followers, has long ago been banned by the law. Persons who make money by its exercise come under the designation of rogues and vagabonds, or some such technical legal classification, and are liable to be dealt with accordingly by summary jurisdiction. In spite of these drawbacks, however, the calling thrives more or less in all parts of the United Kingdom. The police, for reasons best known to themselves, confine their attention for the most part to the operations of the fortune-teller who draws small sums of money from the poorer classes of society. As a rule, those who cater for the well-to-do in this remarkable line of industry are permitted to go their own way without let or hindrance, provided they do not cross the boundary line which lies between innocent and criminal practices. In London the number of persons engaged in palmistry and similar arts is said to have increased enormously of late years. By some curious freak of evolution in a matter of this kind Londoners are not permitted to rule in their own house, but have to trust to the energy and judgment of the Home Office, which controls the police of the metropolis. Of late some public interest has been aroused as to palmists and others of the fraternity. The police, so it is said on apparently good authority, have issued a notice prohibiting in future the advertisements by such persons, whether in the public newspapers, by means of sandwich men, or in other ways. If this be the case the Commissioners of the London police and the Home Office may be congratulated on the logical decisiveness of their belated action. The principle adopted by them is Napoleonic in its directness. Strike at the advertisement and this illegal traffic withers and fades as grass in the oven. Why should not the London police apply a similar wholesome restriction to other forms of objectionable trading?

A Fine Social Field for the Police.

WHAT an enormous field for social reform is thus opened up for the Home Office! A glance through the daily newspapers reveals a number of advertisements of an obviously improper or fraudulent nature, some of them referring to swindles that have been publicly exposed again and again, yet no action is taken by the police who are professedly created to protect the interests of the public. Some of the smaller magazines contain advertisements of a suggestive kind that would probably secure instant condemnation by a magistrate if made the subject of a police prosecution. Then there are the proprietary articles

which have been declared in His Majesty's Courts of Justice to be fraudulent in every particular detail of their claims. Surely the police need have no hesitation in proceeding against advertisers who have been thus condemned in set terms by the highest legal functionaries in the Kingdom. Yet such advertisements—whole columns of them—may be seen in newspapers owned partly or wholly by peers of the realm. Possibly the view of the Home Office is that persons who can afford to throw their money away on such transactions do not deserve protection. That attitude may be an excuse for official inaction, but it is no justification, and it has now been abandoned as regards the palmists. Moreover, it would be based on false assumption, for the patent medicine traffic makes its ill-gotten gains largely from the poorer classes of society. The fact is that the Home Office appears to have sunk into a sort of official slough of lethargy, from which it emerges only under the stimulus of some public scandal such as the detention in prison of a man after proof that he has been wrongfully sentenced. Convincing testimony of the ineptitude of the Home Office is to be found in the lack of prosecution of notorious offenders whose frauds have been repeatedly exposed in the public Press and whose names appear in "cautionary lists" revised and brought up to date from time to time.

The late Dr. Walter B. Cheadle and the "C.P.R."

A CORRESPONDENT has written us pointing out an error in the recent obituary notices a few days ago of his late friend, Dr. Reginald Thompson, who, it was stated, travelled across Canada with Lord Milton along the line which later was taken by the Canadian Pacific Railway. As he knew Lord Milton intimately, and was in Norway with him some time after he had made his Canadian journey, he is able to state that Dr. Thompson was not his companion on that trip, but Dr. Walter B. Cheadle, later Physician to St. Mary's Hospital, who died two years ago. Dr. Cheadle was a friend of Dr. Thompson's, and when Lord Milton made his first trip away for the sake of his health, it was with the late Mr. J. W. Clarke (Registrar of Cambridge University in his later years) and Dr. Thompson in the *Skylark* to Iceland. Dr. Thompson introduced Dr. Cheadle when Lord Milton wanted to start again, as he himself was married and could not go, and the book written by Lord Milton and Dr. Cheadle gave an account of their journey. When Dr. Cheadle married he asked our correspondent to go to Norway with Lord Milton, for Thompson, Cheadle, and the writer were all St. George's Hospital men, Cambridge M.D.'s, and intimate friends. We agree that it is only fair to

the memory of Dr. Cheadle to keep his name clearly connected with that Canadian journey which has become of so much interest and importance in connection with that vast modern enterprise, the Canadian Pacific Railway.

Skin for Sale.

THE voluntary sacrifice of a portion of the integument of a healthy person in order to help in closing the breach in the cutaneous surface of another is an act of heroism that does not often receive publicity. In cases of severe burns, for instance, where skin-grafting is necessary and it is not possible to take a fresh piece of skin from the patient himself, relatives, friends, and even medical men and nurses have frequently parted with fragments of their own dermal tissues in the cause of humanity. The idea of placing a market value upon human skin for the purpose of grafting happened to strike a destitute individual who called in at the Bradford Royal Infirmary the other day with a view of making some capital out of this variety of self-mutilation. The price demanded for a foot of his skin is not stated, though it appears that the man was in earnest about the proposed transaction. Unfortunately for his pocket, his offer was not accepted, there being no case in the infirmary that needed skin-grafting. No precedent, in the shape of a scale of fees for the removal of so many square inches of skin, has therefore been established, and it is unlikely that such dealing in human hides will ever become a popular mode of making a living. It is said that the man in question was a journalist, and, doubtless, if he had been successful in this new line of business, a thrilling account of his experiences, bearing just the necessary personal touch, would have enriched the popular literature of the day. Perhaps even now it is not too late!

The Antiquity of Judicial Hanging.

IN a paper read before the British Association Dr. Wood-Jones presented a study of the lesions caused by judicial hanging in Roman times. During the first season's work of the Egyptian survey of Nubia there was unearthed a series of bodies showing the effects of various forms of violent death. One man actually had the rope round his neck, and a very large number showed a curious lesion of the base of the skull, which was diagnosed as being caused by hanging. Dr. Wood-Jones stated that when skulls of criminals were examined in museums, it was found that this lesion did not exist in men known to have been "hanged." Methods of hanging had been changed from time to time. "Hanging" may imply (1) the hanging of a corpse, (2) the hanging (strangulation) of a living being, (3) or the dropping and hanging used to-day as the form of judicial death in England. The abolition of the old method of strangulation in favour of dislocation by the long "drop" marked a great scientific advance in judicial hanging.

LEADING ARTICLES.

TRUTH ON THE "MEDICAL TRIBUNAL."

THAT doughty journal *Truth* has for many years discharged its self-assumed task of censor of the public morals with zeal and assiduity. In spite of manifold errors, faults and inconsistencies, we are glad to believe that its influence has been on the whole exercised in the best interests of society. One of the attractive points about its earlier editorial methods was the logical way in which its views were presented, so that the reader could see at a glance

the premisses upon which any given conclusion was based. Any other method in an aggressive journal whose mission demands not a little of the swash-buckling style must rapidly and infallibly degenerate into mere abuse. It is with some regret we have noted that since the wholesome control of the late Mr. Labouchere has been withdrawn from the journal in question there has been a strong tendency to drift into the tone of abusive and unsupported assertion so closely associated with the altercations of Billingsgate. An example of this sort of vituperation is to be found in the issue of September 25, 1912, which contains an article from the pen of "Scrutator" on "The Case of Dr. Axham." Almost at the outset of the article we are favoured with a sharply-etched outline picture of ourselves as seen by *Truth*. "A professional journal," the passage runs, "called the MEDICAL PRESS, which has a reputation for the most narrow-minded kind of professional animus, published the other day a malicious and spiteful attack on Dr. Axham, which could only inspire profound disgust in everybody who read it." As the statements about our mental limitation and the effects of our article are unsupported by further proof of any kind whatever, the passage as it stands represents a fragment of scurrilous abuse unworthy of a journal professing great aims and adopting a superior moral tone. *Truth* does not see the matter of Mr. Axham's offence as it is seen by the medical profession, but sheer abuse of a medical journal does not advance the argument one way or the other. The legislature has given medical men the right to determine what is or is not infamous conduct, and to deprive any practitioner of his qualification to practise should he transgress the limits of their definition. Mr. Axham deliberately defied those regulations by administering anæsthetics for an unqualified person, and has now to pay the penalty. The fact that *Truth* regards the medically unqualified person concerned as one upon whom the gift of skilled surgery had descended in some special way in no way alters the offence of Mr. Axham. The law recognises only one sort of medical practice, and in the present stage of modern surgery it is inconceivable that any special manipulative knowledge could exist for any length of time outside the range of its orthodox operators. The same issue of *Truth* contains another article by "Scrutator," in which he rejoices over "A Free Fight amongst Fat Quacks," whose claims he pulverises in the trenchant fashion first made popular by the late Mr. Labouchere. It seems clear, therefore, that the editorial mind classifies unqualified medical practice into the sheep and the goats, for here in one article he upholds "manipulative surgery," or bonesetting, while in another he implies untold anathema on "fat quacks." With regard to the latter, he says, "It is a pretty quarrel, and I trust the next round of the fight will be fully reported by the public press, regardless of the advertising departments." The innuendo thus boldly delivered makes one think of Mr. Eugen Sandow and Mr. Barker, two medi-

cally unqualified persons, who profess to cure many human ailments, and who have in past times been more or less hospitably treated and encouraged in the columns of *Truth* itself. How far is the success of these two individuals attributable to newspaper advertisement? On the strength of the sad case of Mr. Axham *Truth* urges that an irresistible case for the amendment of the Medical Acts is made out. The remarkable statement is added that, "There is no other case in which a professional authority possesses legal power to inhibit a man from the further practice of his profession without appeal to the law courts." We had imagined that absolute powers of suspension were vested in the professions of the law, the church, the army and the navy, and that in each of these, moreover, there existed absolute power of prosecution of those falsely assuming the rôle of authorised practice. We agree with *Truth* that an irresistible case exists for the reform of the Medical Acts, but we differ in holding that the interests of the public demand defence against the practice of ignorant and unqualified pretenders as well as against the newspapers who publish their advertisements and participate in their ill-gotten gains.

THE WORK OF THE METROPOLITAN ASYLUMS BOARD IN 1911.

THE annual report of the Metropolitan Asylums Board for 1911 has recently been published, being the fourteenth year of issue. There is much to interest the medical reader within the now familiar orange covers of this volume. Regarding the work of the Board as a whole, the past year has been marked by two events of considerable importance, one being the transfer by the Local Government Board in November last of the casual poor of the Metropolis to the care of the Asylums Board, and the other the adoption of a new scheme for the accommodation and classification of the mentally defective. The reports made by the Children's Committee to the Board from time to time have prepared the way for the more general recognition of the facts that, as a general rule, these feeble-minded individuals can never be sufficiently improved by the most careful training to take their place as ordinary citizens, so that, therefore, the community must be ready to undertake the burden of their care. Furthermore, there has been a good deal of overlapping between the cases classed as imbeciles and those that are merely feeble-minded by what has often been the accidental circumstance of certification. The work of the industrial colony at Darent has been most encouraging, and now that the unimprovable imbeciles are to be removed therefrom, the future of this establishment bids fair to be even brighter. The total number of institutions under the Board, in addition to the casual wards, is now 46, and the area of the district served is 121 square miles. It is significant to note that both the amount and the dose of diphtheria antitoxin show a considerable increase upon the corresponding figures for the previous year, so that for this disease, at least, the

merits of serum therapy are well recognised. Only seventy cases of smallpox were admitted into the Board's hospitals, of whom eleven died. The mortality among the unvaccinated class was more than three times that of the vaccinated. An interesting section of the report is that dealing with the mistaken diagnosis of cases of infectious disease, the errors being greatest in the case of enteric fever and smallpox in the case of the Eastern Hospital, which had the largest number of cases admitted to any one institution. These facts would seem to indicate that there exists a lack of opportunity for seeing and comparing many cases of the exanthemata with non-infectious diseases. The medical supplement to the report, edited by Drs. E. W. Goodall and F. M. Turner, contains several interesting papers. Dr. Turner having experimented carefully with the Milne injunction treatment of scarlet fever, found that the method did not give absolute immunity against infection, nor was he able to see any modification in the mortality or complications of the disease. An exhaustive paper on the blood pressure in scarlet fever is contributed by Dr. J. D. Rolleston. Good results in the treatment of trachoma by carbon dioxide snow have been obtained in the ophthalmia schools.

THE FINANCIAL SIDE OF PUBLIC HEALTH.

THAT the success of public health work depends to a great extent on the amount of money forthcoming, is a more or less self-evident proposition. A conviction of its truth has long since been brought home to the authorities both central and local, in whose hands sanitary administration has been entrusted. Should a County or a Rural Council stint its expenditure the general health of the district under its jurisdiction must inevitably suffer to an extent which may be roughly gauged by the death-rate, and by the incidence and case mortality of infectious diseases amongst its population. Another illustration is that of the establishment of sanatoria under the Insurance Act. The agitation of a generation has failed in dealing effectively with the stamping out of tuberculosis, indeed, from the standpoint of practical State medicine it may be said broadly that society has merely grasped the fringe of the subject. At length the legislature has realised the fact that in order to face the problem effectually a vast sum of money must be spent in the special treatment and the segregation of tuberculosis patients. The principle underlying that departure is common to every branch of health administration. Not only is that the case but a certain amount of money expenditure is essential to the provision of a wholesome environment. The statistics of any great town will be found to bear testimony to that fact. The death-rate of, say, 30 per 1,000 of population living in a crowded slum sinks to 15 per 1,000 in a wealthy residential suburb. A striking case in point has been furnished in the annual report issued recently by the Medical Officer of Health of the royal borough of Kensington. The large

district for which he is responsible comprises two sub-districts, North and South Kensington, which are about equal in population, but which represent broadly the two extremes of a wealthy and a poor London neighbourhood. The results are written in startling fashion in the death statistics. In the rich South folk die at the rate of 10.2 per 1,000, whereas in the poverty-stricken North they flock to their graves at the rate of 17.3 per 1,000. Children die at the rate of 103 per 1,000 in the South, as against 148 in the North. The birth-rate, on the other hand, in the South was only 10.8 per 1,000, compared with 26.3 in the North. There were last year 107 deaths from phthisis in the North, but only 48 in the South; in fact, there were only eight deaths from that cause recorded amongst "well-to-do" persons. Facts such as these show clearly that a vast deal remains to be done in order to place our public health administration upon a sound basis. Money must be spent freely in all directions needed to secure a satisfactory standard of environment for the individual citizen. Such expenditure must be regarded as a national investment to be returned in the saving to the general fund of wealth and efficiency. What is true of Kensington applies in substance and in fact to every point of the United Kingdom, urban or rural, just as it applies to every practical application of the advances made in other directions by modern medical science.

CURRENT TOPICS.

The Medical Conscience.

THE medical profession of to-day inherits lofty traditions of honesty and humanitarianism from the great men who were our fathers. And as people are usually imposed upon in direct proportion to their goodness and largeness of heart, so few classes of men have done so much unremunerative work as doctors. During the present crisis there are abundant signs that the public in general hold this opinion, for it comes to some of them with surprise that the profession which has always combatted injustice to others should at last insist on justice to itself. There is nothing more nauseating at present than the cynical remark of the mere politician that he had always thought the chief end of medicine to be the healing of disease rather than personal aggrandisement, his puny mind not understanding the relation of the latter to the former. The preservation of our good name as a profession depends, however, not on the attitude of politicians or people, but on ourselves, and our reputation is more undermined by the foes of our own household than by all outside agencies. The surgeon who publicly depreciates medicine, the consultant who blames the practitioner for a fatality, the specialist who tells the patient that the treatment adopted by the family physician is just the very treatment that should not be adopted; in short, all those who try to make themselves shine by the destructive conflagration of another's reputation, lower the pro-

fession more than all the laws ever enforced. What punishment would be sufficient for the consultant who, being called to see a case in the last stages of phthisis, lifted up his pious hands to heaven as he said, "My God, if I had only been called twenty-four hours earlier!" With such as these we may mention the surgeon who operates for a fee and not for a cure or palliation; the hospital physician who fills his beds with petty cases, sent by influential people to save themselves personal inconvenience, to the exclusion of cases of urgency and of those for whom hospital treatment is essential. The sun has spots, but its general brightness is undisputed. For the sake of the illogical we must remove the spots from our profession.

Autotomy.

THROUGH the medium of the lay Press several cases have been brought to the notice of the public in which a surgeon has performed an operation on his own person. One is inclined to attribute such a procedure to bravado, and in some instances the desire to show one's strength of mind and indifference to pain may have been a factor in the performance. We cannot, however, deny that there are several points in surgery that can be elucidated by such means. According to Professor Paul Reclus (*La Presse Médicale*, August 17th), who gives an account of such an operation by a French surgeon, M. Regnault, the chief object of "autotomy" was to demonstrate the efficiency of local anaesthesia for a herniotomy. A preliminary injection of morphia was given, and then the operative area was infiltrated with cocaine. The operation was carried out painlessly and with entire success. We cannot believe, however, that there is much of scientific value in such operations, for the value of local anaesthesia can be fully demonstrated by allowing another surgeon to perform the operation. Nor is the performance of such an operation on oneself an entire novelty; we have simply forgotten the other cases reported. There is, indeed, an authenticated case of a blacksmith who had undergone a perineal cutting operation for stone in the bladder. There was a recurrence of the symptoms, so the patient asked his brother to hold up his scrotum, and assuming the lithotomy position pushed a knife along the track of the old wound into the bladder, removed the stone and made an uneventful recovery. There can be no doubt, however, that surgeons would gain much if they realised, as did M. Regnault, the use of local anaesthesia. In an emergency, given a surgeon and some novocaine tablets, no patient should die without an attempt being made to relieve his condition.

The Redemption of the Inebriate.

ONE of the papers of greatest practical interest to our profession, read at the recent meeting of the British Association, was that contributed by Dr. David Heron, Assistant Professor of Eugenics, in University College, London, on "The Reformatory Treatment of Inebriates." He gave particulars of the records of over 1,900 inebriates who had undergone treatment and had been kept under observation for a

year. Of these only 331 could be said to be doing well or to have reformed. Even this small number would have been considerably reduced had all the inebriates been under observation for periods long enough adequately to test the permanency of reform. The one fact that dominated all others was the amount of mental defect among inebriates. Dr. Heron holds that all the available evidence goes to show that the mental defect precedes instead of being the result of the alcoholism, that, in fact, inebriety is more an incident in the life of the drunkard than the cause of his mental defect. Dr. Heron urged that the only remedy for at least two-thirds of the existing extreme alcoholism was the permanent segregation of the mentally defective child from school age onwards. This subject has been dealt with frequently in the *MEDICAL PRESS* during late years. The cases where inherent mental defect is at the root of causation no doubt form a large percentage of incurable cases; but in a large number the incurable alcoholic habit must be ascribed to the degenerative effects upon the brain and nervous system brought about by prolonged and excessive use of intoxicants. The causation of inebriety is frequently extremely complex, and nothing can be more absurd than the claims of quacks who profess to cure every class of case by drugs and secret remedies. One of these "cures" is still being carried on by a philanthropic society, which numbers among its members, dignitaries of the church, ministers of religion, magistrates and newspaper editors.

A Travelling Scholarship in Dermatology.

ONE of the most important assets of the modern specialist is his knowledge of the various methods adopted by the recognised leaders of his branch in different parts of the world. In the splendid isolation of his own clinic he can put each new and vaunted remedy to the test, thoroughly sifting the results claimed for it by other observers. If he has been fortunate enough to visit the principal foreign clinics, he will have learned first-hand many invaluable "tips" and secrets belonging to his speciality, otherwise he must remain content to read the foreign journals for himself—a poor substitute, it must be confessed, but nevertheless indispensable if he would keep himself abreast of the latest developments of medical science. To the prospective consultant, fresh from the schools, nothing can be of greater service than a tour round the Continental clinics before finally settling down as a specialist at home. Nothing could have been more happily chosen to perpetuate the memory of the late Dr. Radcliffe Crocker, for thirty years physician for skin diseases to University College Hospital, than the generous gift of £1,500 made by his widow in order to endow a travelling fellowship in dermatology in connection with the hospital. This scholarship, which carries with it a gold medal, will, we understand, be awarded every five years, and there is sure to be keen competition among budding skin specialists of the future to associate themselves with the memory of one of the most distinguished exponents of dermatology that this country has ever seen.

PERSONAL.

MAJOR F. KIDDLE, R.A.M.C., has been appointed a Specialist in Ophthalmology at Colchester.

DR. E. H. STANCOMB has been adopted as the Labour candidate at the next Parliamentary election at Southampton.

DR. HERBERT BRUCE LOW, M.D., Ch.B. Edin., has been appointed Honorary Assistant Physician to the Children's Hospital, Sunderland.

DR. ARTHUR J. HALL has been appointed Dean of the Faculty of Medicine in the University of Sheffield, in the place of Prof. Beattie, resigned.

MR. HERBERT CHITTY, M.B., M.S. Lond., F.R.C.S. Eng., has been appointed an Assistant Curator of the Pathological Museum of the University of Bristol.

MR. DOUGLAS RODGER, M.B., Ch.B. Vict., F.R.C.S. Edin., has been appointed whole-time Ophthalmic Inspector of Schools to the Queensland Government.

SIR RICKMAN J. GODLEE, Bart., P.R.C.S., will distribute the prizes at the Royal Dental Hospital, Leicester Square, on Tuesday, October 22nd, at 5 p.m.

MISS C. L. HOULTON, M.B., B.S. Lond., has been awarded the Dr. Edith Peachey Phipson Post-graduate Scholarship at the London (Royal Free Hospital) School of Medicine for Women.

DR. DANIEL KENNEDY, of Nordrach-upon-Mendip, has been appointed temporary Consulting Officer and Medical Adviser to the County of Somerset, in connection with the administration of sanatorium benefit.

SIR JAMES GOODHART, Bart., M.D., LL.D., will receive the guests at the forthcoming meeting of the Pupils' Physical Society, which will take the form of a *Conversazione*, on Friday, October 4th, at 8.45 p.m.

DR. HERBERT RHODES will open a discussion on "Alcoholism and Tuberculosis" at the meeting of the Society for the Study of Inebriety to be held on Tuesday, October 8th, at 4 p.m., at 11 Chandos Street, W.

SIR BERTRAND DAWSON, K.C.V.O., Physician to the London Hospital, will preside at the annual dinner of the Continental Anglo-American Society on October 12th, at the Majestic Hotel, Avenue Kléber, Paris, at 7.30 p.m.

DR. T. WARDROP GRIFFITH, F.R.C.P., Professor of Medicine in the University of Leeds, delivered the Schorstein Memorial Lecture on "Some Cardiac Problems" yesterday at the London Hospital Medical College.

PROF. SIMON FLEXNER, of the New York Rockefeller Institute, will deliver the Huxley Lecture at the Charing Cross Hospital Medical School on October 31st, on "Recent Advances in Science in Relation to Practical Medicine."

DR. H. R. DEAN, M.A., M.D., has been appointed to the Joseph Hunter Chair of Pathology in the University of Sheffield, *vice* Prof. J. M. Beattie, who has been appointed to the Chair of Bacteriology in the University of Liverpool.

SURGEON-MAJOR JOHN FITZGERALD, of Caragh, Co. Kerry, late of the Indian Medical Service, who died on June 25th, aged 75, left personal estate in the United Kingdom valued at £13,821, of which £7,291 is personal estate in England.

DR. J. TATE CREEERY, the well-known Medical Officer of Health of Coleraine, was the recipient last week of a handsome gold watch and a substantial cheque, as a token of the esteem and affection with which he has been regarded by all classes of the community during the last thirty years of zealous and efficient service in the district.

FRENCH CLINICAL LECTURE

ON

PNEUMOCOCCAL MENINGITIS.

By DR LAFFORGUE,

Medecin-Major (premiere classe); Professor, Val-de-Grace.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

THE meningitis which results from pneumococcus invasion (pneumococcal meningitis) has already had an extensive history, clinical and bacteriological. It owes to the important memoir of Netter ("De la méningite due au pneumocoque, avec ou sans pneumonie," *Archives de Médecine*, 1887) the position which has ever since been assigned to it in nosology. A number of subsequent investigators—German, American, Italian—have contributed to make it known; and the researches in France of Boulay (*Thèses de Paris*, 1890-91), of Hutinel (*Semaine médicale* 1892), of Grasset (*id.*, 1894), and of Scherb (*Thèses de Montpellier*, 1894-95) deserve special mention here. Nevertheless, it was until within the past few years frequently confounded with cerebro-spinal meningitis. But pneumococcal meningitis has re-established its definitive autonomy in proportion to the increased precision of the identification of the meningococcus. And at the present date it appears to us as an affection which is clearly individualised, and readily lends itself to nosological description. Following the example of Netter, we are here dealing separately with the meningitis which is associated with pneumonia, and that which is independent of every pulmonary influence. In addition, we reserve a place in our study of the subject for certain meningeal conditions which have arisen in the course of pulmonary pneumococcus invasions, and to which the term meningitis would not duly apply. These we propose to study under the heading of *parapneumonic meningeal pneumococcosis*, so as to indicate simultaneously their necessary differentiation from cases of meningitis, properly so-called, and their habitual coincidence with a pulmonary process.

A. *Pneumococcal Meningitis Associated with Pneumonia*.—Here there are three eventualities possible: (1) The precedence of the pneumonia—which may be from a few days to (a maximum of) three weeks; (2) the simultaneous appearance of both affections; (3) the precedence (or apparent precedence) of the meningitis. The following considerations apply to all these three cases, without much variation.

I.—ETIOLOGY AND PATHOGENY.

The proportion of cases of pneumonia that are complicated with meningitis is very variable (from 0.13 to 8 per cent., according to dates and localities). Two-thirds of the cases occur in the male sex. The degree of receptivity reaches the maximum at the two extremes of age: in the first year of infancy, and among old people after the age of sixty-five. In case of adults, the maximum is reached between forty and fifty years: overstrain of the nervous system, cerebral prophy, renal or hepatic failure, certain physiological conditions (such as pregnancy or lactation) or pathological states (such as extreme poverty, starvation, cachexia, etc.), *alcoholism* (which has been noted in more than one-third of the cases)—these are the most efficient of the known predisposing causes. Among the extrinsic factors, latitude and climate are but of relative importance. But this cannot be affirmed of certain *epidemic conditions*, which are met at variable intervals, and of which the rôle is as manifest in its influence as mysterious in its nature. Under their influence, in regions which had previously enjoyed apparent immunity, there may be developed a very severe outbreak of pneumococcal meningitis. These may then appear in unusual proportion (in Erlangen, for instance, making 8 per cent. of the cases of pneumonia), after having been absent for years. This abnormal frequency of cases of meningitis habitually coincides with the occurrence

of other extra-pulmonary localisations of the pneumococcus: in endocarditis, pericarditis, nephritis, etc. It is in such cases that we see pneumococcal meningitis spreading in epidemic form, like pneumonia itself. Usually circumscribed by conditions of habitation—in single families or grouped collectively (as in barracks, convents, schools and prisons)—these epidemics sometimes extend to a whole village, or town, or city. They rarely spread further, and in this way they differ in course from epidemics of cerebro-spinal meningitis, from which they are further distinguished by less tendency to reappearance in successive years. Instead of the regular and almost rhythmic recurrences which characterised the epidemics of cerebro-spinal meningitis in the 19th century and the beginning of the 20th, they have presented but rare epidemic manifestations, and those separated by long intervals (focal centres appeared in Prussia, Saxony and Silesia in the period which ranged from 1863 to 1868; Italian foci appeared later at Turin and Milan, and the New York epidemic in 1873). On the other hand, an habitual feature of pneumococcal meningitis is the appearance of sporadic cases, not grouped, which display themselves side by side with epidemic cases of cerebro-spinal meningitis in such a way that clinical history alone would be insufficient to distinguish one from the other. Many cases of this class occurred in 1898, 1899 and 1900. This interesting fact seems to prove that the circumstances—probably external—which govern the affinity of the meningococcus or pneumococcus for the meninges are either identical or closely allied.

What, then, is the pathogeny of pneumococcal meningitis associated with pneumonia? According to the explanations (notoriously insufficient as they now are) of Gubler, there have been successively incriminated: venous stasis of the brain (Verneuil), reflex influences transmitted by way of the sympathetic (Laveran), and embolic metastases (Lancereaux). This last-mentioned author attributed the meningitis to emboli detached from the endocardium. But, as a matter of fact, endocarditis is absent in two-thirds of the cases of pneumonia which are complicated with meningitis. It is nevertheless probable that the embolic theory of Lancereaux applies accurately to some cases. Salvy maintained that the meningitis should be regarded as a pyæmic localisation, as it always coincided with the occurrence of pulmonary suppuration. But in a series of 120 cases analysed by Netter, suppuration of the lung was found but in 17—that is to say, in 14.17 per cent.

It is necessary to hold definitely to the thesis which was so brilliantly sustained by Netter in 1887, and was based by him on decisive demonstration, that: *the passage of the pneumococcus into the cerebro-spinal fluid is the causal factor of the meningitis*. The proposition is now trite, indeed; but at the date of its enunciation it represented a very advanced view. By 1878, Professor Grasset had enunciated the opinion that in cases of duplex localisation, pulmonary and meningeal, we had to deal with "a duplex manifestation of the same cause." And this proved to be a clinical intuition of the most exact and suggestive type, which came to be demonstrated bacteriologically by Netter. The pneumococcus may attack the meninges by one of two different routes—(1) starting from the pharynx (Cornil), the nasal fossæ or sinuses (Netter, Weichselbaum), the tympanic or labyrinthine cavities (Netter), where it colonises normally in case of pneumonia, the germ passes into the meninges, either along the blood-vessels or

lymphatics or the lymph-sheaths of the nerves; (2) the pneumococcus may pass directly from the general circulation into the cerebro-spinal fluid. Thus we have two pathogenic mechanisms, either of which is able to account for the invasion of the meninges—that of a *local infection* passing on from one stage to another, and that of a *general infection—a septi-cæmia*—with selective localisation in the meninges. Netter is inclined to believe that the latter is the more usual mechanism. But our recent additions to knowledge of the course of primary pneumococcal septi-cæmia do not tend to corroborate this view.

II.—SYMPTOMS.

The initial pneumonia presents symptoms and habitual signs. In this connection three remarks must be insisted on—(1) the process in the lung does not always take on the classic type of lobar pneumonia; the types of pulmonary congestion, of spleno-pneumonia, of bronchitis, etc., are sometimes observed. (2) Not infrequently the lesion is located in the apex. (3) The period of invasion of these pulmonary lesions conveys frequently some symptomatic peculiarities which would seem to indicate the influence of a precocious meningeal reaction: violent headache, photophobia, retro-cervical pain, vomiting.

The symptoms of the meningitis properly so-called vary according to whether the process does or does not engage the whole extent of the surface of the cerebro-spinal axis; whether it predominates over the convexity—which is the rule—or affects to an equal degree the various areas of the surface of the brain, etc. In basing a classification on the features of evolution we may distinguish *four* clinical types:—

(1) *Hyper-acute, or Apoplectiform.*—This is the most interesting of the types, because the development is insidious, and it lends itself to errors of prognosis which are almost inevitable. The meningeal complication may appear either in the course of the pneumonia, or after the resolution of the latter has been completed. The following note of one of our own cases is an example of the parapneumonic type:—

X was admitted to the Val-de-Grâce, 18th February, 1911; after an illness of some days. The onset had been marked by a rigor, without localised pain in the side; accompanied by cough and sanguinolent sputa, and very severe headache with photophobia and vomiting. On admission, he was found to be the subject of pulmonary consolidation of the lower lobe and a portion of the middle lobe, on the right side. At that period the meningeal signs were so far defaced that, except for the suggestive ones referred to (headache, vomiting) attention would hardly have been attracted to the meninges at all. Lumbar puncture drew off a limp fluid, which flowed without showing tension. Microscopic examination, after centrifugalisation, failed to reveal a *microbe of any kind*; but, on the other hand, there was a *very pronounced and almost pure lymphocytosis*. Cultures proved sterile. Precipitin reaction was negative.

Next day the patient's condition remained the same. But, in the course of the succeeding night, the meningeal syndrome established itself with extreme brusqueness. The patient lost consciousness; uttered unintelligible phrases; displayed extreme agitation; the face was of earthy hue, the nose pinched, the facial muscles twitching, the eyes rolling in the orbits. Myoclonic shocks passed through the upper limbs. Kernig's sign, which had been absent in the evening, became very distinct; rigidity of the nucha was very marked; the abdominal wall was retracted; the vomitings were repeated; incontinence of urine and of feces appeared; and the oculo-pupillary reflexes were but little modified. There was no local paralysis. Another lumbar puncture yielded a very suspicious-looking fluid, which contained numerous pneumococci and polynuclear corpuscles. Death occurred in the course of the day. The autopsy displayed the typical lesions of pneumonia, and of a meningitis which extended along the whole length of the spinal column, and without any other noteworthy visceral lesions.

Netter's memoir gives the history of a case of a

metapneumonic meningitis which belonged to the same evolutionary type as the above. An insidious development of meningitis on a gross scale, very rapid and fatal evolution—with a symptomatology almost dramatic in intensity—such are the principal characteristics of the apoplectiform type. It should be observed that, in our case, the cytology permitted from the onset the suspicion of the approach of a meningeal complication; nevertheless it was but a slight presumption, having regard to the fact that lymphocytosis is a familiar phenomenon in the course of the most varied infections and intoxications. Also, this apoplectic variety is sometimes complicated with hemiplegia, aphasia, etc.

(2) *Acute.*—This is the most usual form; in this case the meningitis develops progressively, and reaches its acme in the course of some days. As the lesions are most pronounced on the convexity, the headache is very pronounced and appears at an early stage; and Kernig's sign, which is nearly constant, indicates the habitual participation of the spinal meninges. We again note the rigidity of the nuchal muscles, vomitings, delirium, incompetence of the sphincters, varied modifications of the oculo-pupillary reflexes. Paralysis of the limbs are exceptional; those of the cranial nerves are less rare—particularly of the facial and auditory—especially when the exudate has been very copious at the base.

(3) *Sub-acute.*—Here the meningeal syndrome is but very slightly developed, and runs a transitory course. It is to cases of this type that the epithet of *meningism* has long been applied. Many of them are related to the parapneumonic meningeal pneumococcosis, which is described below; their course and evolution are favourable.

(4) *Chronic.*—Does a chronic type really exist—that is to say, acute meningeal lesions naturally evolving towards a cure? The occasional cases which have been indicated do not carry with them a degree of absolute conviction; the lumbar puncture not having served as criterion to the diagnosis. Those cases of spontaneous cure belong, possibly, to genuine cerebro-spinal meningitis.

III.—PATHOLOGICAL ANATOMY, CYTOLOGY, BACTERIOLOGY.

The pulmonary lesions vary in intensity. Of 120 cases which were collected by Netter, there were 3 of pulmonary abscess, 14 of purulent infiltration, 25 of gray hepatisation, 18 of red-gray hepatisation; the remainder conformed to the type of ordinary pneumonia, or of correlated inflammatory neuropathies. They are frequently accompanied by vegetative endocarditis (one-third of all the cases), by fibrinous, or fibrino-purulent, pericarditis, or by pleurisy.

With regard to the meninges, we find an exudate—yellowish, viscous, fibrinous, and very richly abounding in micrococci—most conspicuous on the cerebral convexity, and more especially along the course of the vessels. It is also present on the basal surface, and on both aspects of the cerebellum; but there is, as a rule, less coherent and compact than on the convexity. The exudate is incorporated with the mesh-work of the pia mater; which latter structure, on the other hand, is easily detachable from the surface of the brain. The cerebral ventricles are specially affected; the intraventricular liquid is more abundant than in the normal state, and contains small clots of fibrin held in suspension. The choroid plexus forms a continuous fibrino-purulent mass. The spinal meninges are involved in the majority of cases. Netter says, in one-third; but the systematic statistics of autopsies of the spine have displayed the existence of a much higher proportion. It is even probable that no pneumococcal meningitis develops without involving in its attack the whole of the cerebro-spinal axis. It is true that the lesions display varying degrees of intensity, according to the stage of development and the locality; they are specially pronounced at the level of the cervical and lumbar enlargements; they are present in those situations under the aspect of a continuous fibrino-purulent stratum; at least, on the posterior aspect of the pia mater—the anterior portions of this membrane are relatively spared by the disease—and, besides, they

display along the vessels milky streaks, or yellowish non-coherent bands; and, again, in other cases there may be but a simple vascular injection—hyperæmia without exudation.

To these histological lesions correspond *modifications of the cerebro-spinal fluid*, which are revealed by lumbar puncture:—

(1) *In the initial period*, this liquid undergoes but slight modifications: (a) its appearance is often limpid, or but slightly turbid; (b) the increase of tension may be slight or even nil; (c) microbes may be undiscoverable by direct examination, or even by culture; (d) the leucocytic reaction may be absent, or appear only at wide intervals (polynuclear lymphocytosis, or of the intermediary formula).

(2) *In the period of full development*, lumbar puncture brings off a liquid at high or medium tension, turbid or purulent, of a pale yellow or bluish tint, and variable consistence—sometimes viscid. This fluid is highly albuminous, contains fibrin in abundance, and rapidly presents a copious coagulum; this is sometimes even completely formed within an interval of ten or fifteen minutes after the puncture. Microscopic examination, made before, or better after, centrifugalisation gives results which are nearly constant as regards bacteriology, but very variable in respect to cytology. Bacteriological examination reveals the presence of pneumococci in variable quantity; usually, however, in great numbers; free, or enclosed in leucocytes; the majority presenting typical characteristics, and some under the aspect of degenerate forms, more or less refractory to Gram's stain. From the cytological point of view, the results are much more variable; sometimes—indeed in the more usual type of case—we find readily presenting itself in evidence a typical formula of polynucleosis (polynuclear cells, both intact and degenerate); sometimes, again, the polynuclear cells are much less numerous, and centrifugalisation is indispensable in order that the examination of the clot should reveal the formula of classic polynucleosis (A. Mery and Partunier). Finally, in other cases, leucocytes are completely absent; and we find ourselves in presence of this *paradoxical formula: abundant pneumococci, sometimes in pure culture, without any associated cytological elements*. Instances of the occurrence of cases in which the cerebro-spinal fluid of pneumococcal meningitis is either void of, or extremely poor in, cellular structures are not rare (Menetrier and Aubertin, Achard and Ramond, Guillemot and Ribadeau-Dumas, Castaigne and Dobré, Ch. Lesieur, Froment and Garin, Guillain and Cl. Vincent, etc.). They have elicited variously divergent pathogenic interpretations. According to some authors, the cause lies with the chemotaxis. When the pneumococcus is but slightly virulent, the organism is but lazy in defending itself; hence the leucocytic afflux is either nil, or small in quantity. But when the microbe is highly virulent, its secretions repel the leucocytes and extinguish their vitality; hence paralysis of the cellular defence, and extreme poverty of the liquid in leucocytes. According to Professor Widal, however, the mechanism is wholly different: in the spinal canal itself, there occurs a *precipitation—a retraction*—of the fibrin comparable to that which takes place *in vitro*; and the coagulum so formed envelopes the leucocytes which, by virtue of that fact, disappear almost completely from the surrounding liquid. The results of a puncture made in the case of one of our patients go to support the idea of the pathogenesis which is maintained by Professor Widal. On account of an operative incident, the procedure took place in two sittings at an interval of three hours. In both portions of the fluid evacuated, an abundant supply of pneumococci was evident; but, while the first portion was *extremely fibrinous, and extremely rich in polynuclear cells* which were *nearly all involved in the coagulum*, the second portion was almost completely free from fibrin and leucocytes. How explain these differences, after an interval so brief? We can hardly admit that it was merely due to a simple chemotactic variation. And if this explanation appears applicable to the case of the leucocytes, it surely cannot be applied to the fibrin.

Thus, it is more plausible to admit that unknown factors (involved in the operative traumatism, effusion of blood, etc.) created conditions favourable to precipitation and retraction of fibrin. This is, at least, a plausible hypothesis—regarding an interesting question which is still a disputed one.

With regard to the cytological point of view, we are now able, in bringing our own personal observations into juxtaposition with those which had been previously published, to present in the following table the several leucocytic formulæ of pneumococcal meningitis:—

(a) Polynucleosis.

(b) Lymphocytosis: initial, transitory, and rapidly followed by polynucleosis (cases observed by Triboulet, Ribadeau-Dumas, Menard, and ourselves);

(c) Absence of leucocytic reaction.

IV.—DIFFERENTIAL DIAGNOSIS.

Meningitis co-existing with pneumonia is liable to be confounded with one of various pathological states. The following are some examples:—

(a) Tuberculous conditions (caseous pneumonia, for instance), complicated with the final granulation process.

(b) Pneumonia complicated with cerebral phenomena attributable to hæmorrhage, cerebral or meningeal; to cerebral embolism, cerebral abscess, thrombosis of the sinuses, etc.

Clinical examination will here assist in forming the diagnosis; but, in order to eliminate meningitis with certainty, it is necessary to have recourse to the lumbar puncture. The same observation, and same precept, must be regarded when distinguishing pneumococcal meningitis from every other variety of active meningitis (here including even tubercular meningitis). Clinical observation furnishes us with presumption only; bacteriological examination of the cerebro-spinal fluid leads us to certainty. This includes the following series of operations:—

The liquid derived from the lumbar puncture should be divided into three portions—one destined for direct examination, one for cultures, and the third for inoculations. All must be received aseptically in sterilised tubes.

(1) *Direct Examination on Slides*.—This may be applied in case of the total mass of fluid, or to the deposit obtained by centrifugalisation. Examination of the original mass of fluid suffices, as a rule, for bacteriological diagnosis; examination of the deposit after centrifugalisation is indispensable to determination of the cytological formula. Centrifugalisation should be carried out some minutes after the puncture, for in liquids in which pneumococci are present a fibrinous coagulum is very rapidly formed, which involves in its meshes nearly all the leucocytes. If the centrifugalisation must be postponed, the liquid may be defibrinated at once by placing it in a receiver containing glass beads. In the positive cases, direct examination will reveal: (1) Diplococci in lanceolate arrangement, encapsuled, and taking the Gram stain; (2) a cytological formula of polynucleosis (70-90 per cent. of polynuclear cells). We may have different results in all of the early phases of the meningeal process: (a) Absence of microbes; (b) Lymphocytosis. This is, however, soon replaced by polynucleosis.

(2) *Cultures*.—These may be carried out with specimens of the general mass of liquid (when the germs are numerous) or of the deposit (when they are few in number), on the various media usually employed; and also, in addition, on *serum-broth* and *ascitic jelly* when available. In case of the pneumococcus, the culture on the latter (in form of dewdrops) should be characteristic of this microbe. In the cases which prove difficult of identification we may utilise all the various other complementary methods of culture; these may be adapted to the characters of the germ which were made manifest in the previous cultures.

N.B.—In preparing for the broth culture it is well to dilute the cerebro-spinal fluid with large quantities of the medium (to a tenth, or so).

(3) *Inoculation*.—This may be practised subcutaneously on the guinea-pig ($\frac{1}{2}$ - $\frac{1}{2}$ cc.) or the rabbit (2cc.). When dealing with the pneumococcus, death by

septicæmia takes place after an interval of twenty-four to seventy-two hours. The microbe multiplies in the blood. We can always identify it absolutely by appropriate cultures made with blood taken from the heart.

N.B.—When the germs are proportionally few, the inoculations should be practised with portions of the deposit diluted in physiological serum.

(4) The preceding modes of examination should be finally supplemented by application of the *precipitin* reaction of H. Vincent; this gives a negative result in cases of pneumococcal meningitis.

V.—PROGNOSIS.

The prognosis of a case of pneumococcal meningitis cannot be based upon clinical evidence alone. In fact, if the acute and hyper-acute cases are almost surely fatal, we have seen apparently very grave cases recover—which seemed, indeed, at first to be destined to the same fatal evolution. It is quite true that in some of these, in absence of the lumbar puncture, some doubt may be cast on the legitimacy of the diagnosis. The prognosis should be founded on a double basis—that of the clinical condition, and that of the bacteriological examination of the cerebro-spinal fluid. When the latter displays abundant microbial proliferation, the fatal result is assured. And the only cases which would appear to be curable, whatever be the apparent gravity of the clinical tableau, are those in which the meningitis is of the purely circulatory, or but very slightly exudative, type; when the anatomical process is still compatible with recovery (Grasset). These cases correspond to a proliferation of the pneumococcus of slight relative proportion—so slight that Belfanti, not being able to demonstrate its presence, incriminated the toxins of that microbe—and such that special artifices are necessary to discover it at the time.

VI.—TREATMENT.

This may also be very deceptive at the time of the full development of the clinical conditions. The usual sedatives may be employed to allay the symptoms of excitement. The use of the warm bath at 40 deg. (104 deg. F.), every three hours, and the lumbar puncture every day, continue to form the principal basis of the treatment. We must still wish for the discovery of a specific serum of appropriate efficiency.

B. Parapneumonic Meningeal Pneumococcosis.—There are cases in which the passage of the pneumococcus into the sub-arachnoid space does not result in the production of a true meningitis—in the anatomical and clinical sense of this term. The pneumococcus has indeed penetrated, as the culture of the same bears witness, into the cerebro-spinal fluid; but its proliferation takes place in extremely scant proportion—so scanty that direct examinations, even when carried out with the aid of centrifugalisation, do not succeed in placing it in evidence; and even culture itself sometimes proves powerless to reveal its presence, unless we have recourse to special artifices. In those cases, with the exception of a certain degree of hypertension, the cerebro-spinal fluid retains its normal characteristics; the cellular reactions are usually very slight—and, in the majority of instances, are due to a distinct lymphocytosis (R. Voisin, Lafforgue)—or even completely absent (Ch. Lesieur, Froment and Garin). From the clinical point of view, facts of this order have been included under the title of “meningism”; with rare exceptions, indeed, the meningeal symptoms are greatly reduced in number and importance. In one of our own cases they consisted merely of a violent headache, a slight degree of nuchal pain, a Kernig's sign almost obliterated and reduced to a spontaneous flexion of the leg on the thigh when the patient passed from the recumbent to the sitting position. Nevertheless, it is not rare to find the participation of the meninges in the infective process evidenced from the outset by the presence of two symptoms which are sufficiently rare in the pneumonia of the adult—repeated vomitings, and pain on pressure of the eye-balls, accompanied by photophobia. The pathogeny of those meningeal conditions appears to be superposable on that of meningitis, properly so-called.

The diagnosis of these cases is difficult enough. In order to establish its accuracy, it must not be based on the semeiological nuances above referred to; the lumbar puncture must constitute the sole decisive criterion. It is but in exceptional cases that the pneumococci will be revealed by direct examination, on slides, of the centrifugised liquid; the germs being very few in number, it is *only by culture and inoculation* that we can be able to place them in evidence. Nevertheless, in order that the culture should be more surely positive, it will be useful to have recourse to certain artifices, of which the importance has been demonstrated by one of our own cases: (1) Large quantities of the cerebro-spinal fluid should be used for cultures (in case of one of our patients, 5 cc. remained sterile, while the culture gave a positive result with 30 cc.); (2) the cerebro-spinal fluid should be diluted with a considerable volume of the culture medium used (dilution in proportion of 1:10 for each examination). MM. Lannois, Lesieur and Gauthier have, indeed, shown that the cerebro-spinal fluid is a medium which often proves very unfavourable to the successful culture of microbes; thus there is, accordingly, an advantage gained by diluting it, so as to avoid its hindering influence, as a drag upon the process of evolution in presence of culture. It is indeed probable that cases of this type—which are still pretty rare in medical literature—will not fail to become more numerous if we regulate our procedure systematically according to the method described.

The immediate prognosis appears to be favourable. Is this also the case with regard to the remote prognosis? These meningeal episodes, even when apparently transitory and curable, constitute, in actual fact, a thorn and a gnawing torment for the future.

The treatment of cases of pneumonia complicated with meningism may be allowed to depend mainly on balneotherapy at high temperature. The desirability of practising lumbar punctures systematically is much more questionable; these find their principal indication in the persistence of the meningeal syndrome. And here we may appropriately recall the fact that MM. Lesieur, Froment and Garin have maintained by the verification of the existence of a masked meningeal pneumococcosis a new pathogeny of pneumonic hemiplegia. Their observation, taken in addition to that of Mouisset and Lyonnet, is of the most suggestive type.

C.—Pneumococcal Meningitis without Pneumonia.—The developments associated with para-pneumonic or meta-pneumonic meningitis seem to promise us to become extremely extended in connection with meningitis without pneumonia. Sometimes it is but a rigorously isolated manifestation of the infection; in other cases it succeeds to some other pneumococcal determination—endocarditis (Jaccoud), otitis (Leyden, Senger, Netter), coryza (Raymond), uterine infection (Caussade and Logre), etc. Whether primary or associated, it recognises the same pathogeny as para-pneumonic meningitis; while it also displays the same clinical forms, determines the same lesions, and conforms to the same rules of diagnosis and of treatment. The labours of Scherb have demonstrated the gravity of the diagnosis in cases of the acute type. The feature which has long constituted the special interest of this form of disease is the mere fact of its existence—the fact, which has been prominently placed in evidence by Netter, that the pneumococcus is susceptible of exclusive localisation on the meninges, without any other preliminary visceral determination. Beyond this point, which is firmly established at present, we can but repeat, in connection with this subject, the considerations which have already been enunciated when considering the subject of meningitis with pneumonia.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Mr. A. A. McConnell; F.R.C.S.I. Subject: “The Decompression Operation for Cerebellar Tumour.”

ORIGINAL PAPERS.

THE CLINICAL SIGNIFICANCE OF
THE ALBUMIN REACTION IN
SPUTUM.

By MAURICE FISHBERG,

Visiting Physician, Tuberculosis Ward, Montefiore Home; Adjunct
Attending Physician, Lebanon Hospital, New York.

THE difficulties frequently encountered while attempting to ascertain the character, or the underlying pathological process, in cases which are suggestive of pulmonary tuberculosis are well known to every physician in active practice. In doubtful cases, which we meet more often than we should like, anything is welcome which may be of assistance in deciding the true nature of the disease with which we are dealing. It appears to me that the chemical examination of the sputum in cases of suspected tuberculosis deserves more attention than has hitherto been accorded to it. My experience with the albumin reaction of sputum during the last eighteen months has been so satisfactory that I can unhesitatingly recommend it as a useful adjunct in all cases in which tuberculosis is suspected, especially those in which the bacilli are slow in revealing themselves by the usual microscopical examination. Indeed, it is of frequent occurrence that while waiting for the bacilli in the sputum, valuable time is lost and the case progresses beyond the stage considered incipient.

In a previous communication by Dr. D. Felberbaum and myself, it was shown that the sputa in about 97 per cent. of all the cases of pulmonary tuberculosis react positive as regards albumin, while sputum of cases of bronchitis, pulmonary emphysema, rhinopharyngitis, etc., never gives an albumin reaction. Some cases of advanced phthisis, especially the fibroid cases, as well as some in which the disease is quiescent, occasionally give negative reaction, but with each exacerbation of the disease albumin is sure to make itself evident in the sputum. The test has become so valuable in my experience that whenever I do not find a positive albumin reaction in the sputum, especially in incipient cases, I do not hesitate to exclude tuberculosis.

The chemical examination of the sputum has been pursued for many years. In 1855 Biermer pointed out that in chronic bronchitis the quantity of sodium chloride and mucin is considerable, traces of extractives can also be detected, but albumin is never found. In pneumonia Biermer found in addition to the above also albumin and blood pigment. Albumin in large proportions was also found in sputum of pulmonary oedema, while the sputum of pulmonary tuberculosis he found presenting the same characters as that of bronchitis. Many others have discussed the chemistry of the sputum, especially Renk, Kassel, Jacobsohn, Lanz, Pankow, and Starkow. In his monograph on this subject, Wanner was the first to show that the chemical examination of the sputum is of great importance in cases of suspected pulmonary tuberculosis. His investigations led him to the conclusion that albumin is never found in cases of uncomplicated chronic bronchitis, while in tuberculosis the albumin reaction is never absent. Indeed, it was his opinion that albumin is present in all cases of inflammation of the parts from which the sputum is derived. Whenever the differential diagnosis between pneumonia and pulmonary infarction is in question, the presence of albumin in the sputum, provided there is no admixture of blood, speaks in favour of pneumonia.

This test was, however, neglected and hardly used by those who treated the most cases of tuberculosis till, in 1900, H. Roger and Lévy-Valensi, of Paris, in several articles on the subject showed that in cases of pulmonary tuberculosis the sputum never fails to give a positive albumin reaction, while in bronchitis and pulmonary emphysema, provided they are not complicated by dilatation of the heart, the albumin reaction is always negative. Roger and Lévy-Valensi in their last paper on the subject have compiled all the available data, compiling the examination of the

sputum in 1374 cases by various observers showing that the albumin reaction is always positive in cases of pulmonary tuberculosis, and negative in bronchitis. Roger insists that while the absence of albumin in the sputum positively excludes tuberculosis, its presence is no positive indication of the disease, because albumin may also be found in sputa of cases of pneumonia, pleurisy, oedema of the lungs, pulmonary emphysema with cardiac dilatation, etc. On the other hand, in that large number of cases met with by all practitioners in which the differential diagnosis between bronchitis and pulmonary tuberculosis is difficult, a positive albumin reaction of the sputum decides in favour of tuberculosis.

In America there have to date been published two papers on this subject: one by Lawrason Brown and W. H. Ross, and the other by D. Felberbaum and the present writer. Brown and Ross report findings in 116 cases of tuberculosis, and arrive at the conclusion that all patients with tubercle bacilli in the sputum react positive to the albumin test in the sputum. In agreement with Roger's opinion, Brown and Ross state that a positive reaction by itself is of little diagnostic value, but when the reaction is repeatedly negative in a patient without the symptoms of acute miliary tuberculosis it is probable that no active pulmonary tuberculosis is present.

In the paper published by Dr. Felberbaum and myself we arrived at the following conclusions: "On the whole, our results do not confirm Roger's statements to the effect that in every case of tuberculosis the sputum gives a positive albumin reaction. We found some cases of undoubted tuberculosis in which careful analysis of the sputum gave negative results. In forty-two specimens of sputum showing the presence of tubercle bacilli, the albumin test was also positive. It has been our experience that the number of bacilli present in the field has no relation to the amount of albumin found by the chemical test. Some specimens of sputum showing an enormous number of bacilli had only a faint trace of albumin, which was sometimes so slight as to render it altogether doubtful whether the reaction was positive. It appears that the activity of the process has considerable influence on the intensity of the chemical reaction. In active, progressive cases the amount of albumin is greater than in quiescent or healing cases. In fibroid cases the amount is often infinitesimal, or entirely absent."

Ever since that paper was published, I have pursued this test in all the cases of tuberculosis, as well as others characterised by the elimination of sputum, both in hospital and private practice. At the Montefiore Home, where all the cases under my care are in the advanced stages of the disease, my experience has been about the same as that reported in the mentioned paper, with one important exception: I have observed that some sputa derived from undoubted tuberculous cases and giving a negative albumin reaction at one examination often react positively at a subsequent analysis. This is particularly true of fibroid phthisis, which often runs a slow quiescent course. But during acute exacerbations, albumin almost invariably makes its appearance in the sputum. On the whole, I find that over 95 per cent. of cases of pulmonary tuberculosis in the advanced stages of the disease give a positive albumin reaction.

From further experiences with sputa from 167 cases of incipient, or moderately advanced cases of tuberculosis, as well as with many more cases which were not tuberculous, I can state that in this class of cases this test is even more valuable than in the later stages of the disease. In many cases in which the diagnosis could not be determined with certainty the presence or absence of albumin in the sputum was invariably decisive. This is especially true of cases of post-grippal bronchitis or tracheitis, which are so frequently met with during the fall and winter months. They often show symptoms and signs strongly suggestive of tuberculosis, which clear up in the course of time—occasionally several months. Inasmuch as a negative microscopical examination is usually not decisive in this sort of case, anything that may help

us in arriving at a correct conclusion is welcome. It has been my experience that in all these cases, when the sputum reacts negatively as regards albumin we can safely exclude tuberculosis. In several cases in which in former times I would have suggested to the patients that they had better take measures advisable in incipient tuberculosis, because the signs and symptoms they presented warranted a tentative diagnosis of this sort, I have relied on the negative results of the albumin reaction and have not been disappointed.

Forty-six specimens of sputum from cases of bronchitis and tracheitis gave negative albumin reactions. Some of these were quite puzzling, especially those which were sequelaë to influenza. But inasmuch as a negative microscopic examination is not always conclusive, the albumin test is really useful in this sort of case. From my experience I am strongly inclined to the opinion that in all these cases a negative albumin reaction decidedly excludes tuberculosis.

Specimens of sputum from six cases of pleurisy showed a positive reaction in four, all of which were pleurisy with effusion. Two cases of dry pleurisy gave negative albumin reactions, and one case of empyema also reacted negatively.

Five specimens of sputum from cases of lobar pneumonia all gave a positive albumin reaction — two rather faintly so.

Three cases of whooping cough, two in children and one in an adult, all gave a positive albumin reaction of the sputum. The case in the adult was quite interesting. The patient, a woman, was treated for several weeks by her family physician for tuberculosis. When she presented herself before me, I found physical signs of diffuse bronchitis, no tubercle bacilli in her sputum, but the chemical test gave a strongly positive reaction as regards albumin. She accidentally dropped a word to the effect that her child had been giving her trouble, as it suffered from whooping cough, which led me to make further inquiries as to the onset, symptomatology and course of her disease; this convinced me that I was dealing with a case of whooping cough. The further course of the disease was uneventful, but the albumin in the sputum persisted for about two months until the cough ceased altogether.

Twenty cases of asthma gave negative albumin reaction. Three cases of asthma with emphysema, complicated with dilatation of the heart, gave a positive albumin reaction occasionally. I am inclined to the opinion, based upon a careful observation of one of these cases, that whenever the overworked heart gets into difficulties and shows signs of failure, albumin begins to appear in the sputum, but as soon as the heart is reinvigorated through proper measures, rest, digitalis, etc., the sputum again reacts negatively. Considering the rarity of cardiac dilatation in pure asthma, it is important to remember that the albumin reaction is of great service in differentiating it from tuberculosis. Especially is this the case with that form of asthma which is often seen in furriers. Unlike the cases of essential asthma, these are quite often complicated by tuberculosis or are tuberculous from the beginning. The physical signs are those of diffuse bronchitis or of asthma, and owing to the sibilant and sonorous noises heard all over the chest it is difficult, often impossible, to differentiate them from tuberculosis by the physical signs alone. Until two years ago I relied solely on the symptomatology and bacterial findings in attempting to formulate a diagnosis in these cases. Those showing rapid loss of weight, weakness, tachycardia, night sweats, etc., as well as those in whose sputum tubercle bacilli were found, were considered tuberculous. But others were simply told to give up their work at fur. But at present I look at the albumin reaction as an aid of great importance. Whenever it is positive I do not hesitate to pronounce the case tuberculous.

The numerous rhino-pharyngitic patients who consider themselves tuberculous, and are often even admitted to sanatoria as cases of tuberculosis with negative sputum as regards tubercle bacilli are well known. In my experience sputum from these cases is always negative as regards the albumin reaction. I never

hesitate in assuring the patient that he is not tuberculous when I find a negative albumin reaction.

In twelve cases of pulmonary emphysema, without cardiac dilatation, the sputum always gave a negative albumin reaction. In two cases in which the heart was giving way, and dyspnoea and cyanosis made their appearance, albumin was found in the sputum. In one of the two latter cases, which I had under observation for some time, the sputum reacted negative as long as the heart worked properly, and only when the pulse ran up to over 100 and cyanosis, dyspnoea, etc., made their appearance, did the albumin reaction become positive. To a certain extent, I am under the impression that we may, in pulmonary emphysema, take the albumin reaction as an index of the capacity of the heart.

In sixteen cases of heart disease, I found a positive albumin reaction in four; the rest reacted negative. In five cases of chronic nephritis, I found a positive albumin reaction in three.

It appears from what has been said that the albumin reaction of sputum is a useful adjunct to our diagnostic methods in cases of suspected tuberculosis. Considering that the technic of the test is so simple—anyone who can test urine for albumin can perform it—it ought to become a routine diagnostic method.

Some precautions are, however, necessary. The sputum should be collected, just as for microscopic examination, in a wide-necked bottle. It must be examined on the very day it has been expectorated, because with putrefaction the proteids are split up, especially the mucin, and liberate albumin. Especially during the summer months, sputum, just like urine, must not be examined when putrefaction has set in. Similarly, we must be careful to obtain sputum, from beneath glottis, and not saliva, which contains albumin. This is particularly true in cases of stomatitis, but many patients bring specimens of sputum which on examination is evidently saliva. These specimens are to be rejected.

The albumin test is made as follows: a three per cent. solution of acetic acid is added to the sputum, which is then thoroughly shaken. During ten or fifteen minutes the bottle is allowed to stand, and repeatedly shaken during this time. It will be observed that the mucus is coagulated by the acetic acid, and when it is then filtered through paper into a test tube, the filtrate appears as a clear fluid. Occasionally all the mucus is not coagulated with the first attempt, and this is easily ascertained by adding a drop of acetic acid to the filtrate, which in such cases again shows flocculi collecting as a precipitate. The process is then repeated, until a clear filtrate is obtained. The clear fluid is then boiled over a Bunsen burner, or an alcohol lamp, and while boiling, some crystals of common salt, or a concentrated solution of sodium chloride is added. If albumin is present there results a cloudiness, or a curdy precipitate which, on standing, settles to the bottom of the tube. Roughly speaking, the amount of the precipitate gives us an idea of the amount of albumin present. The most important precaution to be observed is that nothing but a curdy precipitate can be considered as positive, because the presence of mucus, which the acetic acid does not always dissolve completely, may also give a cloudy precipitate on boiling. But this reaction is not curdy, nor does it settle on standing. Of course, any of the other tests for albumin may be used on the filtrate, but the above procedure has given me satisfactory results.

CONCLUSIONS.

1. The albumin reaction of sputum is a useful test in cases suggestive of pulmonary tuberculosis and will often be of assistance when the microscope fails to reveal tubercle bacilli.
2. A positive albumin reaction is not always decisive, because many diseases, not at all tuberculous in character, may show albumin in the sputum.
3. A negative reaction, when repeatedly found during several examinations, from specimens of sputum carefully collected, excludes tuberculosis.
4. In cases of tuberculosis, in which the albumin reaction was positive but has become negative for

some time, we may conclude that the process of cicatrization of the pulmonary lesion is progressing favourably, even when the physical signs are slow in disappearing.

5. The albumin reaction has a prognostic value. It gives us an opportunity to follow the progress of the tuberculous process. Whenever albumin makes its appearance in a case in which the reaction was negative for some time, there is surely to be found an acute exacerbation, or an extension of the lesion in the lung.

6. In pulmonary emphysema a positive albumin reaction appears to be an indication of cardiac dilatation, thus indicating the proper treatment to be pursued.

SUBPHRENIC ABSCESS.

By FRANK JEANS, M.A., M.B., B.C.CANTAB.,
F.R.C.S.ENG.,

Honorary Assistant Surgeon, Royal Infirmary, Liverpool.

THE term "subphrenic abscess" means any localised collection of pus in contact with the under surface of the diaphragm. Strictly speaking, it includes abscess of the liver, although clinically we recognise a distinction between the two. In some cases a liver abscess may become strictly subphrenic, having been originally separated by a thin layer of liver tissue, this layer ultimately undergoing absorption.

There are certain anatomical factors concerned in the formation of a subdiaphragmatic abscess which must not be lost sight of, although one feels after operating upon these cases that too much stress must not be laid upon exactly where the abscess ought to be. Roughly speaking, the space immediately below the diaphragm is divided anatomically by the ligaments of the liver, with four peritoneal compartments. These are the falciform, which divides the space laterally into two halves, a right and a left, and the coronary ligaments, stretching outwards to form the lateral ligaments, thus sub-dividing the lateral spaces into anterior and posterior compartments. In addition there are two non-peritoneal or retro-peritoneal regions between the two layers of the coronary ligaments. Now, of the four peritoneal compartments—right anterior, left anterior, right posterior, left posterior—the two posterior spaces are by far the most important. This is easily explained by the same facts, the recognition of which has led to the adoption of the semi-recumbent position and suprapubic drainage in cases of acute general peritonitis.

The pelvis and the posterior fossa under the diaphragm are the two main cavities in which are liable to collect all serous or purulent effusions in the peritoneum when the patient is lying down. The very fact that subphrenic abscess does not usually attack people in the best of health, but occurs secondarily in patients who have just partially recovered from some acute or sub-acute abdominal lesion, *i.e.*, in people who are lying down for the greater part of the day, is enough to show the part which gravity alone may play in its production.

The effect of gravity is seen also in the relative frequency of posterior location of the pus, a fact which is important to realise, because, although cases which come to the front are more easily diagnosed, those which come to the back are more easily drained. Another anatomical factor, which Mr. Moynihan would, no doubt, call the "physiology of the living," is the direction of peritoneal currents. Dr. Arthur Wallace showed many years ago, and other observers have confirmed it, that the direction of the flow in the abdomen is upwards.

As a rule the causation of the abscess is obvious, but occasionally one meets with a case in which not even the pathologist, who is allowed a much larger incision than the surgeon, can say what the primary lesion was.

In my own cases the number is too small to draw any conclusions from; but in the collection of cases on which Mr. Barnard wrote a very able paper the figures were as follows:—

Gastric ulcer	21 cases
Appendicitis	12 cases
Liver: suppurating hydatid...	8 cases
Liver: tropical abscess	6 cases
Duodenal ulcer	5 cases

the remaining cases being made up of one or more of the following:—Gastric cancer, liver abscess, pylephlebitis, suppurative cholangitis, splenic abscess, pyæmia, parturition, pneumonia, bronchiectasis, empyema, periostitis of vertebrae, cancer of pancreas, cystic kidney, ruptured intestine, typhoid, gall-stones, and pyosalpinx, while in two the cause was not found.

The commonest age appears to be between 20 and 30, coinciding, that is, with the commonest age of appendicitis and ulcer either of the duodenum or stomach.

The diagnosis is not easy. The history of the lesion causing it may or may not be present; and it is worthy of note that in those cases due to gastric or duodenal ulcer a history is more likely to be advanced than in those due to appendicitis. This is partly because the more serious types of appendicitis are often first attacks, and no previous attack, therefore, is recorded.

The onset is sometimes sudden and sometimes insidious, and these characteristics are so evenly balanced that the onset can be taken into account only in association with symptoms pointing to a local cause.

If the commencement of the disease is very sudden it may be mistaken for the causative lesion; but this in itself is not a disadvantage, because operation is undertaken immediately and the real state of affairs disclosed.

The general signs and symptoms vary a good deal, but the history of most of the diagnoses made is this: You first of all form an impression that pus is present in the body somewhere. Then you exclude the abdomen, the pelvis, and the thorax. Then you think of subphrenic abscess and call in a physician. The diagnosis, it is true, is in some cases so simple that the surgeon can make it himself, but in the majority of cases he is wise if he avails himself of the help of a skilled physician.

The patients strike one forcibly as being ill. They have the signs of a more or less severe toxæmia; most of them lose weight, and nearly all of them have a rise of temperature at some time or other. In many cases, however, this rise is not great, and it is worth remarking that Hippocrates recognised a fact which seems to have been lost sight of occasionally, in spite of the invention of the clinical thermometer—namely, that fever is more likely to be present during the formation of an abscess than after it has formed.

Of the general symptoms, rigors constitute the most serious single sign. There is usually anæmia, night sweats, dirty tongue, and in many cases a type of septic diarrhoea.

Abdominal Signs.—These are present in the form of a swelling in about two-thirds of the cases. The swelling, when present, is usually due to the pus and its surrounding adhesions, but in some cases it is the liver which is felt. It is a fact that when the pus is between the diaphragm and the liver, the liver is not pushed down, for two reasons—(1) it is adherent; (2) it is easier for the diaphragm to be pushed up, so that if anything moved it would be this structure.

The note is, as a rule, dull on percussion; but if the communication with a cavity such as the stomach still persists, it may be tympanitic owing to the contained gas. Thoracic signs are always present, and usually unilateral. They are:—

- A. Displacement upwards of the lung.
- B. Dry pleurisy.
- C. Pleural effusion.
- D. Compression of the lung.
- E. Consolidation of the lung.
- F. Bronchitis at the base.

It is noteworthy that the heart is not usually displaced laterally, though often pushed upwards.

In the borderland between the thorax and the abdomen there are many holes into which one may tumble. Anything which is too high to be felt in the

abdomen and too low to give pronounced and definite signs in the thorax is likely to be overlooked. The pus in a subphrenic abscess is, of course, underneath the diaphragm, and not in the thorax anatomically. But practically, and as far as its clinical signs go, it is in the place where the thorax ought to be.

The question of the advisability of using an aspiratory needle for diagnostic purposes can roughly be summed up by saying that it is not quite safe unless one is prepared to operate immediately, and in any case its best use is during the operation.

The natural history of the condition, if not treated surgically, is likely to be one of three possibilities. It may burst externally. I have experience of one case of this kind in which I had previously operated for a large appendicitic abscess. The patient was, however, too far from Liverpool to be X-rayed, and too ill to be moved. The signs were vague when I saw her, and appeared more like those of multiple abscesses of the liver. The pus discharged ultimately above the umbilicus.

The second possibility is rupture into a cavity, and Barnard gives the frequency in his collected cases as follows:—

Into a bronchus, 4; pleura, 5; stomach, 8—*i.e.*, a return to where it came from; intestine, small, 1; colon, 2.

Even when they rupture externally, or into the bowel, the patients are not necessarily cured. The danger, therefore, of allowing the abscess to rupture spontaneously is too great to justify one's considering it for a moment.

The third possibility is that the patient, if left alone, dies of toxæmia and exhaustion.

The London Hospital statistics give a mortality of 12 out of 12 cases treated without operation. If we turn to the surgical (or unnatural) history, we find a mortality of 37 per cent.—a high one, it is true, but an improvement on one of 100 per cent.

CASE I.—F. T.; æt. 21; female. Dr. O. T. Williams' case. Eight weeks' history, left-sided pain, one rigor, one attack of vomiting, lay on left side. Temperature 101.2°, pulse 120, respirations 30. Right side, liver felt one inch below costal margin; left side, a fixed and tender mass reaching down to navel, not moving with respiration. P.N. impaired. Under left costal margin a hard, firm tumour felt, continuous with splenic dulness above. Thorax dulness from the 6th to the 12th rib downwards; left base moving badly. Urine contained streptococci once previously; bacilli coli once previously. X-ray examination showed diaphragm raised. Operation: 12th rib removed, perirenal tissue separated, pus found easily above right kidney, tube passed up to diaphragm. No gas in pus. This was probably a left extra-peritoneal abscess, and Dr. O. T. Williams considered it was primarily an infection of the right kidney. Recovery normal.

CASE II.—W. O.; æt. 32; male. Pneumonia. Four months before lost 4 stone in weight. When seen, lay on left side. Bulging 6th to 10th space, right side, local tenderness, lower expansion diminished. P.N. dull from 5th rib downwards. Dulness extending down to two inches below costal margin in the nipple line, tender on percussion. X-ray marked bulging up and diminished movement. Operation: 10th rib and 8th rib resected and pus drained. Patient lost his earthy look, and left in three weeks. Smears from pus and agar cultivations disclosed nothing. This, I believe, may have been a case of pneumococcal origin. It is unusual for the infection to spread downwards, but in the absence of any other cause the pneumococcus may be blamed for the infection. The fact that the agar remained sterile is rather in favour of this view.

CASE III.—Woman; æt. 48. Fourteen days ill. Appendix abscess opened under gas. One month later appendix removed; three weeks later subphrenic abscess opened; four weeks later left hospital perfectly well. Bacteriology: Streptococci grown from subphrenic abscess.

BACTERIOLOGY.

With regard to the bacteriology of subphrenic

abscess, it is obviously possible to be certain only in cases which are submitted to operation, or which prove fatal. There is, however, even in cases treated surgically, a second difficulty. A localised abscess in the peritoneum implies a certain amount of resistance on the part of the patient. Further, an abscess hidden underneath the diaphragm must be of some considerable size before it is clinically or radiographically recognisable. If the patient survives this period of abscess formation and localisation, the pus is often of an extremely low degree of virulence, having caused severe symptoms more by reason of its quantity than its quality. The result to the bacteriologist may be a sterile tube.

Now, it is important to know not only the organism, but to have a culture of it, since vaccine treatment, however disappointing it may be when stock vaccines bought at a shop are used, is found to be often efficient if it is autogenous.

In obtaining the specimen the delicacy of the organisms must be remembered. One of mine was sterile, having died of cold on its way to the Thompson Yates Laboratory. Hence the pus from these cases must be treated with the greatest possible kindness.

I have been associated in the treatment of two other cases not included in those I mentioned, in which the offending organism was actinomycosis.

As to which operation is to be performed, the loin incision is recommended if the infection is rather diffuse, and the trans-thoracic route if it is localised. They should always be drained from behind, even if they have to be examined from the front.

The position of the patient depends upon the site of the abscess, but it is as well to find out, before the anæsthetic is given, what attitude proves the least embarrassing to his respiration.

When the patient is on the table the needle can be used, and a more exact localisation of the pus made. A rib is resected, usually the 10th, and the intercostal muscles sewn to the diaphragm before an opening is made through it.

One reads descriptions of sewing two layers of pleura together, that is, costal pleura to the pleura over the diaphragm; but this savours rather of a description of an operation intended for those who are never likely to perform it, and written by someone who has never done it. There is not enough tissue in the pleura alone to provide a good hold.

After incising the diaphragm one hopes to find the pus, and here again one has been told to put a finger in and define the abscess cavity and break down septa between one loculus and another. But I have never been able to do much through a hole made by the resection of only one rib. Whether in operations for empyema or for subphrenic abscess, I have steadily avoided all mischievous exploratory investigations.

In fact, in some cases I cannot describe exactly where the pus was, having, in short, preferred the curing of the patient to being able to write an elaborate description of the precise anatomical boundaries of the abscess.

Having let off some of the pus as gradually as may be necessary, the surgeon makes it his first duty to keep a specimen of it. For drainage, a rubber tube is the one I have used in these cases, and it measures 1½ inches in diameter. Wide drainage for a short time is better than narrow drainage for a long time. After a few days it is split, thus lessening its rigidity, and allowing the walls of the cavity to fall in without pocketing.

Lastly, in those cases in which, owing the condition and situation of the patient, it is possible to have an X-ray examination made by Dr. Holland, it adds much to the confidence with which the surgeon can attack these always serious cases.

THE King has granted permission for the Hammer-smith memorial to the late King Edward VII., which takes the form of an endowed cot in the West London Hospital, to be called "King Edward VII. Memorial Cot." The tablet to be placed over the cot will bear the Royal Arms.

RUPTURE OF INTESTINE IN HERNIAL SAC.

By R. ATKINSON STONEY, F.R.C.S.I.,
Visiting Surgeon to the Royal City of Dublin Hospital.

RUPTURE of a coil of intestine in the sac of a hernia as the result of external violence must be of sufficient rarity to make the notes of such a case worth placing on record.

Mrs. C., æt. 46, was admitted to the Royal City of Dublin Hospital on the afternoon of Saturday, July 8th, 1911, with the following history:—About mid-day, while standing on a chair placed on a table in a front garden, in order to watch the Royal procession, the chair slipped and the patient fell to the ground, striking her right groin against the iron handle of the gate as she did so. She was wearing a double femoral truss at the time, as she had suffered from double femoral hernia for many years. She was quite confident that the hernia was not down when she was standing on the chair before the fall. Immediately after the accident she was "doubled up with the pain," and felt faint, and vomited. When admitted to hospital about three hours later, her temperature was 97 and pulse 80, the abdomen was soft and moved with respiration, there was pain and tenderness in the right groin, both above and below Poupart's ligament, but there was no sign of bruising of the skin. The truss which she had been wearing had a large oval pad covered with soft flannel. In the evening the temperature was 100 and the pulse was 80, there was very little pain and there had been no vomiting. The patient was only allowed sips of milk and soda-water, and hot stupes were applied to the groin. The bowels moved naturally during the night. The next morning, Sunday, the 9th, the temperature was 97.8, the pulse 100 and respirations 20. The liver dulness was normal; the patient complained of a good deal of pain in the right iliac fossa. The abdomen was not distended and moved well with respiration; there was no rigidity. She was given a simple enema with no result. Orders were given for the pulse to be taken every hour, the hot stupes were continued, and only a mouthful of fluid was allowed occasionally. During the day the patient vomited frequently; at 7.30 that evening her pulse had risen to 122, her respirations to 28 and temperature to 98.4. The abdomen was somewhat distended, though still soft and moving with respiration, and there was no rigidity even over the iliac fossa. As at 10.30 p.m. the pulse rate had increased to 136, and the liver dulness in the mammary line was decreasing, it was decided to operate. The patient was brought to the theatre at 11.30 p.m. and anaesthetised with ether. The abdomen was washed with ether and painted with iodine. On making an incision through the outer border of the right rectus, purulent fluid but no gas escaped. Several coils of intestine, covered with lymph and agglutinated by it, appeared immediately under the incision. One of these coils had a perforation about the size of a threepenny piece with everted mucous membrane almost completely closing the opening. The omentum was spread out in the neighbourhood, slightly adherent to the inflamed coils of intestine and shutting off fairly well the general peritoneal cavity. Gauze wipes were introduced under the edges of the incision to localise the area of infection, and the perforation was closed by two layers of silk sutures. The surrounding pus was swabbed out, no attempt being made, however, to remove the lymph from the coils of intestine; the kidney pouch was clean, but the pelvis was full of turbid fluid without any smell, whereas the pus in the neighbourhood of the

perforation had a distinctly faecal odour. This fluid was mopped out as thoroughly as possible. Two large split rubber tubes filled with iodoform gauze were introduced, one to the bottom of Douglas's pouch and the other to the iliac fossa close to the perforated coil; the gauze wipes were removed and the wound closed except where the drainage tubes emerged. Two pints of saline were injected into the axilla during the operation. The patient was placed in the Fowler position in bed and half a pint of saline was given slowly by the rectum every hour during the night; all of this was retained.

The following morning (Monday, 10th) the pulse was 110 and strong, and the temperature was 98.6. As the patient ceased to retain the salines a simple enema was given, and after two hours' interval the salines were resumed and were retained. In the evening the patient was allowed 1 oz. of fluid by mouth every half hour. During the night most of the rectal salines were not retained, so in the early morning 2 pints of saline were injected into the axilla. The next day (the 11th) a turpentine enema was given and resulted in a small constipated motion. As there was no vomiting, patient was allowed 1½ ozs. of fluid every half hour, and she was also given a pint of saline by the rectum every four hours, which was retained. The wound was then dressed for the first time. There was a considerable discharge of pus from both tubes on the removal of the gauze wicks. That night the patient had three fluid motions and vomited a little several times. The following day (the 12th), as the vomiting had stopped, the patient was allowed 3 ozs. of fluid every hour and the salines were discontinued. The pulse was strong and varied from 110 to 120, and the temperature was about 99 deg. From this on the patient was dressed every day as there was a copious foul-smelling discharge from the wound, but no trace of faecal material. The stitches were all removed on the 15th. During this time the patient suffered severely from diarrhoea, having as many as 14 motions in the 24 hours. But after the first week she made a steady recovery, the discharge from the wound gradually lessening, and she finally left the hospital with the wound soundly healed on August 11th.

The successful result of the operation was fortunate, considering the delay of nearly 36 hours after perforation. This delay was partly due to the difficulty in obtaining the patient's consent to operation; but for the first 24 hours after the accident it was hard to realise that there was a serious intraperitoneal lesion, taking into consideration the history of the occurrence and the condition of the patient. From the patient's account of the accident and the appearance of the truss, it was quite impossible to see how a rupture of the intestine in the abdomen could have been caused, and as the patient was quite positive that the "rupture was not down" at the time when she fell, it was thought at first that there was no very grave injury. The continued absence of rigidity also favoured this conclusion. However, on Sunday evening, nearly 36 hours after the accident, the steadily rising pulse rate, gradually increasing distension and commencing loss of liver dulness, with the continuance of pain and vomiting, showed that there must be some serious trouble in the abdomen, probably intestinal perforation and commencing peritonitis. It was therefore decided that no further time should be lost, but that an exploratory operation should be performed. In the light of what was found at the operation, it is probable that the intestine was forced into the hernial sac during the act of falling and was then burst by the

sudden blow on the pad of the truss as the patient's groin hit the gate-handle; subsequently, but before admission to hospital, the ruptured coil slipped back into the abdomen. The fact that the intestine was burst, and not cut or crushed by the truss, is proved by the appearance of the opening, which was nearly circular, with the mucous membrane everted and no sign of surrounding bruising. The sudden compression of the distended coil of intestine in the confined space of the hernial sac caused it to burst in much the same manner as children burst a paper bag.

THE RELATIONSHIP OF THE NATIONAL INSURANCE ACT TO THE VOLUN- TARY HOSPITALS, ESPECIALLY THOSE WITH ATTACHED MEDICAL SCHOOLS.

By W. McADAM ECCLES, M.S.LOND.,
F.R.C.S.ENG.

INSURANCE against sickness is most wise, especially when it is contributory. To be satisfactory it must always be associated with adequate medical treatment, and medical treatment of a proper character cannot be cheap.

The public as a whole are not fully aware of the enormous advance of medicine in all its branches during the last fifty years, nor of the fact that this advance has necessitated greater expenditure. It is false economy to endeavour to obtain cheap, and therefore in many instances inefficient, medical attendance. This is true in relation to private medical practice, but it is even more true in relation to hospital treatment.

The National Insurance Act must necessarily have a profound effect upon the work and income of the general practitioners of medicine. It will effect little if at all the income of the consultant, but it will produce considerable changes in connection with the hospital on the staff of which he is, and on the medical school wherein he teaches. It is to review some of these possible changes that has induced me to write this article. The opinions expressed may not find acceptance with all, but they are at least worthy of consideration, and time alone will show whether they are justified or not. It is my hope that by thus stating them and attention being thus drawn to them, some unhappy results either to patient or hospital may be avoided.

The National Insurance Act (1911) may affect a voluntary hospital in many ways. The effect may be upon:—

- (a) The patients.
- (b) The medical staff.
- (c) The finances.
- (d) The employees.
- (e) The medical school, if there is one attached.

THE PATIENTS.

There are three classes of patients in connection with a number of the voluntary hospitals—out-patients, in-patients and maternity patients, the latter being both out-patients and in-patients.

Out-patients.—Persons who attend a hospital as out-patients may be classified as follows:—

- (a) Adult males.
 - (i) In work. These for the most part will be insured persons.
 - (ii) Out of work through chronic ill-health, incapacity, idleness, old age, etc. These for the most part will not be insured persons.

Probably the number in Class 1 will be increased, chiefly because more men will "declare sick" on account of small ailments

than before, and will drift to the voluntary hospital, especially if their "insurance doctor" considers their ailment too minor a matter to require his treatment. This drifting to the hospital will entail, if the patients are admitted to the casualty department, a good deal of extra work in determining whether the ailments are genuine or no.

Probably the number in Class 2 will also be increased, as there will be many who will drift to the voluntary hospital after "sickness" and "medical benefits" are exhausted. Possibly others who are dissatisfied with their medical treatment from their "insurance doctor" after attending him for a given time will gravitate to the hospital and swell the number of out-patients unless their admission as such is checked.

(b) Adult females.

- (i) In work: These for the most part will be insured persons.
- (ii) Married women not in work, chronic invalid women, old women, etc. These for the most part will not be insured persons.
- (iii) Women who are entitled to "maternity benefit."

Probably the number in Class 1 will be increased, chiefly for the same reasons as given under males.

Probably the number in Class 2 will not be increased.

Probably the number in Class 3 will not be increased.

(c) Children.

These will not be insured persons, and the number attending any voluntary hospital will not be altered by the Act.

In-patients.—Persons who are admitted as in-patients into a voluntary hospital may be classified as follows:—

(a) Adult males.

- (i) In work. These for the most part will be insured persons.
 - (ii) Out of work. These for the most part will not be insured persons.
- Probably the number in Class 1 will be increased, chiefly for the following reasons:
- (a) Practitioners will insist, and rightly, on patients entering hospital for surgical operations more often and earlier than before, e.g., cases of hernia.
 - (b) Patients themselves will recognise the desirability of early hospital treatment.

Probably the number in Class 2 will not be increased.

(b) Adult females.

- (i) In work. These for the most part will be insured persons.
- (ii) Married women not in work, chronic invalid women, old women, etc.
- (iii) Women who are entitled to receive "maternity benefit."

Probably the number in Class 1 will be increased, and for the same reasons as given under males.

Probably the number in Class 2 will not be increased.

Probably the number in Class 3 will not be increased.

(c) Children.

These will not be insured persons, and the number admitted as in-patients will not be altered by the Act.

Reviewing, therefore, the persons who will be either out or in-patients at a voluntary hospital now that the Insurance Act has become law, it will be seen that there will probably be an increase in the

number, and therefore that the work and the expenditure of the hospital will be correspondingly increased.

Although the Act does not provide for any treatment in a general voluntary hospital, it is likely that many of the "insured" will consider that they have a "right," because they have paid insurance subscriptions, to admission to hospital both as out and in-patients. If this happens to be so in the future, it may cause some amount of friction in the matter of admission or its refusal.

There is another point of view from which the relationship of hospitals to the Insurance Act can be seen, and that is, the Act may tend to make the hospitals more and more the centres for consultation between the "insurance doctor" and the consultant. This can only be for the good of all, provided that the general practitioner himself does not abuse the privilege by referring patients to hospital who should rightly pay a moderate fee to a consultant.

The question has already been mooted as to whether any insured person should be received for treatment at a voluntary hospital. The answer obviously is that the hospital should be placed at the disposal of any necessitous person, but that the authorities of the hospital should reserve to themselves the right of refusing to treat those persons for whom the State has, or appears to have, made provision.

THE MEDICAL STAFF.

The working of the Act will affect both the visiting and the resident medical staff.

Until the Act has actually been in working, it is a little difficult to say precisely its effect.

But at the present time there is some uncertainty as to the proper attitude for the members of the staff of a voluntary hospital to adopt towards the Act. It is quite certain that necessitous persons when ill, even if insured, must receive treatment. Many consultants on the staff of the hospitals have agreed not to work under the Act until the just demands of the profession have been secured. It would, to my mind, have been the only right and wise course if every medical officer attached to a voluntary hospital had taken such a pledge. Supposing, therefore, the Insurance Commissioners refuse or have not the power to grant these demands of the profession, what should be the attitude to be taken by the staff of a voluntary hospital? It may be the duty of the authorities of the hospital to see that the hospital and its funds are not abused by their being used for insured persons, but the voluntary worker on the staff of a voluntary hospital has simply a duty to the patient who needs a service, and is not acting under any contract thereby. Still, it would never do for this voluntary service to be a loop-hole whereby service under the Act is given by one branch of the profession against the wishes of another branch of the same profession. Until, therefore, matters are made much more clear by the outcome of actions of the Insurance Commissioners, the members of the staff of a voluntary hospital are bound to treat the sick.

Up to now the medical staff of a voluntary hospital have always been ready and willing to treat any person provided two conditions subsisted, that the person was ill and therefore required treatment—and that the person was too poor to pay for such treatment as the hospital alone was able to provide. But under the Act the State undertakes to provide "medical" treatment, for which payment is to be made from "medical" benefit. There is, however, no clause or section in the Act whereby adequate payment is to be made to the hospital for such treatment as can be carried out only at a hospital,

and no clause for any payment to be made to the staff of such a hospital for their services. Care will, therefore, have to be taken that this is not another means whereby medical practitioners are made to perform gratuitous service to those who can afford to pay at least in part for such treatment.

Another matter will also need careful watching, and that is the filling-in and signing of necessary certificates under the Act. This should certainly not fall upon the already over-worked resident staff. No provision is made for the payment of anyone in connection with such certificates when the "insured person" is a patient at a voluntary hospital.

There may be a tendency also for that harmonious and humane relationship which now exists between most patients and doctors in this kingdom to be so altered as to bring about strained conditions. When a person thinks that he has a right, on account of contribution to an insurance fund, to the services of a medical practitioner, much of the personal and friendly relationship is apt to disappear. This would be a grave pity if it were an outcome of the working of the Act.

THE FINANCES.

Income.—The income of a voluntary hospital, at any rate in London, is derived from the following sources:—

Annual subscriptions	25 per cent.
Donations	11 "
Hospital Sunday Fund	5 "
Hospital Saturday Fund	3 "
Workpeople's contributions	9 "
Patients' contributions	9 "
Interest from investments	32 "

Thus it will be seen that there are several sources of income which may be threatened by compulsory contributions under the Insurance Act—viz., annual subscriptions, workpeople's contributions, and possibly donations, and the Sunday and Saturday Funds.

There can be no doubt that some who contribute regularly to hospitals will find that they cannot give as much or at all when they have made their compulsory contribution to the Insurance Fund. Workpeople who now contribute out of their wages may be quite unable to do so as well as to pay their weekly sum towards their insurance. Hence it follows that from these sources it may be that the sum accruing to the hospitals will be diminished. At the same time, it is to be hoped that those who can afford to contribute larger sums out of their abundance will be induced to do so rather than let these necessary and helpful institutions suffer, and therefore the ailing poor go without adequate hospital treatment. The awakening of the nation to the value of early and good institutional treatment may even have the effect of increasing the yearly income of the voluntary hospitals.

Expenditure.—But while income may diminish, may remain the same, or may even somewhat increase, the expenditure is likely to become certainly larger. This will be caused by increase of the number of patients, and increase in the expense of thorough treatment.

Grants from Insurance Funds.

There are two possible ways in which a voluntary hospital may receive grants from Insurance Funds, viz. :—

(a) Under Section 12, subsection 2 (c) of the Act.

(b) Under Section 21.

Under Section 12, subsection 2 (c) it is enacted that should a person, being a member of an approved society, be an inmate of a hospital supported by charity or by voluntary contribu-

tions, and the person has no dependants, then his or her "sickness" benefit (or her "maternity" benefit, even if she has dependants) shall, if an agreement has been made between the society and the hospital, be paid in whole or in part towards the maintenance of such person in the hospital.

A little consideration of this possibility will show how rare will be the payment to a hospital, except in the case of "maternity" benefit.

Further, it will require a definite prearranged agreement between the approved society and the hospital, and it is likely that this may lead to serious complications.

Under Section 21, it shall be lawful for an approved society or Insurance committee to grant such subscriptions or donations as it may think fit to hospitals. Such contributions can only come out of surplus funds, and there is no evidence that any such will exist, and even if they do, and contributions are made, the amount cannot in any case be equivalent to the expenditure of the hospital in the treatment of "insured persons."

Supposing money were to be received by the hospital, its acceptance from an organised outside body, such as an approved society, might lead to a request for some amount of control so as to check the expenditure of the grant.

Further, as the money would virtually be received from State funds, it would be the means of suggesting State control in the future.

Neither of these external methods of control would, in my opinion, be beneficial to the majority of the voluntary hospitals, and particularly those with medical schools attached to them.

THE EMPLOYEES.

Every one of those employed by a voluntary hospital whose income does not exceed £160 a year, and is not in receipt of a pension of at least £26 a year, will be required to become "insured persons." Included among these will be:—

- | | | |
|-----------------------------|--------------------------|--------------|
| (1) Nursing staff. | } Nearly all of these | |
| (2) Wardmaids. | | } are women. |
| (3) Hospital kitchen staff. | | |
| (4) Scrubbers. | } Most of these are men. | |
| (5) Clerks. | | |
| (6) Porters. | | |

The hospital out of its own resources will have to find the employer's contribution for all of these.

In addition to this the employed will have to contribute their share, or the hospital will have to do it for them.

In return for the amount thus contributed there would be "medical benefit," "sickness" benefit, and a small "sanatorium" benefit; and possibly, in a few cases, "maternity" benefit. Up to the present most of those employed at the hospital have received their medical treatment free of charge, and will probably continue to do so.

Thus all that part of the contribution which should go for "medical benefit" will be lost, unless the employee is treated outside the hospital. It would seem imperative also that in order to obtain their "sickness benefit," such "insured persons" must not receive board and lodging from the hospital.

THE MEDICAL SCHOOL.

There is very little doubt that for the next few years the effect of the Insurance Act will be to make the parents and guardians of prospective medical students think twice before they put those over whom they have control into the medical pro-

fession. This condition of things must act deleteriously, for the time being at least, upon medical schools, and may rather seriously interfere with their efficiency by considerably diminishing their income.

Further, the altered relationship of many of those who attend the hospital as patients, because they will almost certainly claim a "right" for their treatment, may make them unwilling to be of value for clinical teaching. Tact, however, may overcome this, but great care will have to be taken that there is no interference with a liberal and willing supply of such material. At present nothing could be better than the relations which subsist between doctor and patient in our British medical schools, and it would be a sorry day if anything in the way of legislature were to alter the conditions which are now found working so smoothly.

CONCLUSIONS.

It is yet too early to allow of any concrete pronouncement as to the effects of the National Insurance Act upon the voluntary hospitals, but there are indications that the Act may have very distinct results so far as these splendid institutions are concerned, and it is well, therefore, to be prepared to meet the effects so that as little harm as possible may result, and this ought to be done without any interference with the beneficent action of the working of the Act on behalf of the sick of our country.

OPERATING THEATRES.

EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL.

CASE OF INGUINO-FEMORAL HERNIA.—MR. J. E. ADAMS operated on a boy, *æt.* 5, who had been admitted for operation on a hernial swelling which had been noticed ever since the child began to walk. The swelling had increased in size since an attack of whooping cough five months before admission. There was no visible hernia, but a definite expansile impulse was present in the right inguinal region when the child coughed, and the right side of the scrotum was larger than the left.

The usual oblique incision for the radical cure of inguinal hernia was made. The region of the external abdominal ring was fully exposed, but neither a hernial sac nor the spermatic cord could be found to emerge at this spot. The aponeurosis of the external oblique was therefore divided in the line of the incision, but the inguinal canal in its lower part was empty. The testis was then pushed up from the scrotum and the tunica vaginalis opened. It was then found that a probe could be passed *viâ* the tunica vaginalis into the abdomen; this hernial sac of the complete congenital type was seen to pass beneath Poupert's ligament towards the internal abdominal ring. It was clear, therefore, Mr. Adams pointed out, that he was dealing with a congenital inguinal hernia in which the testis and patent funicular process had reached the scrotum by emerging at the internal abdominal ring, traversing the outer half of the inguinal canal and passing downwards on the outer side of the pubic spine. The sac was dealt with in the customary way for treatment of congenital inguinal hernia—namely, by dividing the sac at the upper end of the testicle, separating it by transfexion and cutting it away; the lower end was left open. On freeing the neck of the sac, Poupert's ligament was pulled upwards to reach the internal abdominal ring. The exploratory incision through the external oblique, which had not divided the pillars of the external abdominal ring, was closed with a few catgut stitches and the skin wound sutured with salmon gut.

Mr. Adams remarked that in a case of this description one might have been tempted to say that a

mistaken diagnosis had been made, seeing that no sac could be discovered, even after the aponeurosis of the external oblique had been divided, but the inguinal canal appeared also to lack a spermatic cord, therefore it was necessary to start exploration from below. An incision of the tunica vaginalis, which contained an excess of fluid but no hernial contents, enabled him to prove its continuity with the general peritoneum, and thus the abdominal course which had been traversed by the tunica vaginalis and testis was demonstrated. Such inguino-femoral sacs, he said, are described, but as far as he was aware they occur mostly in connection with congenital sacs. The crural variety of misplaced testis is well known, and, in such cases as the present one, the testis must have passed this position and yet have gained the interior of the scrotum.

The after-history of the case was perfectly satisfactory; the wound healed by first intention, and the child was discharged ten days after the operation.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Sept. 28th, 1912.

DIARRHOEA OF PITHISIS.

DIARRHOEA, like other complications preventing proper alimentation of phthisical patients, constitutes a serious accident in the course of that disease.

It can depend, says Dr. Thomas, on three distinct causes—hyper-alimentation; certain drugs intolerated; lesions of the intestine due to bacilli of Koch from swallowing virulent expectoration.

Diarrhoea from the first cause is particularly due to the ingestion of fats, consequently cod-liver oil, sardines, butter, etc., should be avoided. The régime will consist in raw meat, powdered meat, vegetables, white of egg, and alkaline water.

Milk is variably borne according to the individual: for some it forms one the best elements of nutrition, for others it is not tolerated. Kephir might take its place, and from the presence of lactic acid the diarrhoea is diminished.

In rebellious cases the digestive tract should be given rest, only rice water allowed for some hours, after which subnitrate of bismuth and pægoric might be useful.

Diarrhoea due to bacillary infection is generally very rebellious to treatment, for the irritation of the intestinal mucous membrane is kept up by the presence of granulations and ulcerations. The diet will be chiefly vegetarian.

Several drugs have been prescribed with varying results: phosphate of lime (2 dr. daily), tannigene (10 gr. three times daily), dermatol (1 dr. daily), oxide of zinc, salicylate of bismuth (1 to 2 dr. daily). Glycerine seemed to have given remarkable results in the hands of Bouchut:—

Glycerine, 10 oz.

Rum, 4 oz.

Three tablespoonfuls a day in hot milk.

In very obstinate cases methylene blue has succeeded—

Methylene blue, 2 gr.

Lactose, 10 gr.

For one wafer; three daily.

GERMANY.

Berlin, Sept. 28th, 1912.

At the sixth Congress für Geburtshülfe and Gynäkologie, one of the first subjects that came up for discussion was the

TREATMENT OF WOUNDS OF THE PERITONEUM.

Hr. Brouha, Liege, said that mechanical irritation of the peritoneum was dangerous. It should be

cleansed dry; washing even with physiological solution was dangerous. All antiseptic preparations should be avoided with the exception of a weak tincture of iodine, which might be made use of for pedicles and suspicious places. The use of gloves was an advance in the prevention of operative infection. It was especially important to leave the serosa dry after operations. For this purpose the field of operation might be shut off by careful packing with compresses. This would also assist in procuring the arrest of hæmorrhage. In all cases of post-operative peritonitis the wound should be reopened as early as possible.

Hr. Meyer, Copenhagen, said that when there was no question of coarse impurities (remnants of food, faces, etc.), washing out of the abdomen was rather harmful than useful. A very searching cleansing of the peritoneum, especially as regarded blood, was not necessary. Drainage of the peritoneum was useless or harmful so long as it was not for the purpose of draining; encapsuled collections. No great weight need be attached to the "peritonealisation" of wounds of the peritoneum, especially when it could not be accomplished without fixation or displacement of intestines. It was better to shut off such wounded surfaces in the small pelvis from the rest of the peritoneal cavity.

Hr. Franz, Berlin, said that every peritoneal wound should be looked on as infected. All investigators who had examined the peritoneum after operation had found bacteria. It was impossible to operate without the entrance of germs. In the great majority of cases these germs did no harm, as they only fall on to the peritoneum in small numbers, they were not virulent, or they were destroyed by the protective power of the patient's system. The hands of the operator and his assistants were dangerous. Rubber gloves removed this danger. The patient's skin, when it was not germ free, could be made so, or sufficiently so, by tincture of iodine. The covering of the skin with antiseptic cloths was a necessary complement of disinfection. The germs of the air were not dangerous. The chief danger lay in the germs already within the body of the patient (as in twisted pedicles, necrotic tumours, germs from bowel, bladder, decomposed myomata, tumours of the adnexa, carcinoma of the uterus, etc.). Germs from the bowel were particularly dangerous, which wandered through uncovered surfaces of bowel or were forced through by gaseous distension within. The dangers arising from the "auto-germs" of the patient could be diminished or removed by the operation. The abdomen should be opened with very small incisions; transverse ones were better than longitudinal ones. Full narcosis was desirable in order to save the intestines as much as possible. Lumbar anæsthesia was particularly suitable for gynecological operations. Blood-cyst fluid, amniotic fluid, and pus should be kept out of the abdomen as much as possible; if it had got in it should be removed as gently as might be. Every little particle, however, need not demand the trouble of removing, and it was better not to flush out. Drainage should only be resorted to when large raw secreting surfaces were left that could not be covered over, and especially where the wound was smeared over with pus. Drainage should only be carried out through the abdominal walls when it could not be done through the vagina.

Dr. H. Macnaughton-Jones, London, said that bactericide and other irritating chemical fluids should be kept away from the peritoneal cavity. Sterilised physiological solution was the most suitable agent. Pus, blood, contents of cysts were a source of irritation when they found their way into the peritoneal cavity; they gave rise to exudation and peritonitis. Asepsis of the abdominal cavity could not be obtained without complete arrest of bleeding and complete covering of all denuded places with peritoneum. Disinfection of the bowels after operation by bowel disinfectants was also of importance. Peritonitis, as a result of manipulation of the bowel, could be almost completely avoided by attention to the following point: efficient drainage for removal of included fluids. It was, as a matter of fact, an extremely rare occurrence.

AUSTRIA.

Vienna, Sept. 28th, 1912.

At the meeting of Oculists in Bohemia this year the principal subject of discussion turned on

MENDEL'S LAW OF DEVELOPMENT.

Pick quoted his experiments in vegetable and animal life and contended that the same law prevailed in the human genus. The eye diseases closely followed parental defects such as neuritis optici, hemeralopia, and others, as Nettleship endeavoured to prove long ago, but few oculists since that time have given us such practical knowledge as confirms any law.

Elschnig here gave the history of a series of moderate and severe cases of myopia hypermetropia, retinitis pigmentosa and albinism, and found that the higher forms of myopia agreed with Mendel's law, but in the others it failed. In a family of 50 descendants where the parentage had retinitis pigmentosa only one isolated case appeared.

Hofmann recounted his experiments with rats which he commenced to breed at the Physiological Institute of Innsbruck and has continued at Prague where the development of the bulbus of the eye has gradually shrunk to a state of anophthalmus or microphthalmus. The anomaly existed greater on the female side than the male and when the abnormal male was confined with the normal female the production was almost normal. There is, therefore, a good deal of complication in arranging any law of generation.

Nutrition, water and surroundings cannot have any influence on the results, as Innsbruck and Prague are very different and yet the final conditions are the same. Lederer next gave a description of his experiments on the manometric measurement of the internal pressure of the eye which he conducted with a fine cannula in an anti-posterior direction through the cornea and lens. When the conjunctiva or oculomotor was irritated with thread or electricity the mercury rose in the manometer at every movement of the eye. Voluntary movement was conducted in the monkey, and the same result obtained as in the guinea-pig. In a patient where enucleation was performed he obtained the same pressure when movement occurred, but when the eye was brought to rest a distinct fall of 5-10 millimetres of the mercury took place. This he thought was at variance with the theoretical discussions that had previously taken place. Waldstein recorded the history of 20 cases of enucleation for malignant tumours and acute micotic irido-cyclites, which he treated subsequently with vaseline and paraffin. This he considered was the best method of preventing inter-ocular infection. Where enucleation was impracticable excentration of the fluid of the bulbus could be replaced by injecting paraffin and serve two purposes, disinfection and cosmetic. Zirm gave the history of a few cases of traumatic cataract which occurred through extraction by the circular operation with extrusion of the iris producing sympathetic ophthalmia in the other eye 24 days after. The vision fell to counting the fingers at 1 metre, but after rubbing with mercury and injecting tuberculin the vision improved to 5-20.

In conclusion he condemned extracting the lens without first performing iridectomy which was an important step in the operation as pressure on the ciliary nerve produced sympathetic ophthalmia and often led to serious consequences in the opposite eye. A similar pressure on the stump of the optic nerve after enucleation produced the same trouble and when not so severe inflammation and reddening which when continued for some time produced toxins with various bacteria that were thrown into the circulation, finally causing great destruction.

CANADA.

Montreal, Sept. 16th, 1912.

ANNUAL MEETING OF THE CANADIAN MEDICAL ASSOCIATION.

(Continued from page 336.)

A DISTINCTIVE feature of the meeting, and in fact a

unique happening at a medical meeting, was that sermons dealing with health matters were preached by visiting medical men at the Edmonton churches. Sir James Grant, of Ottawa, who, in spite of his 83 years is still strong and vigorous, occupied the pulpit of Knox Church. He chose as his text, "Turn ye, turn ye; why will ye die?" and delivered an eloquent and impressive discourse on various matters connected with health and sanitation. Dr. Bruce Smith of Toronto preached in the Metropolitan Methodist Church, taking as his text, "It doth not appear what we shall be. The earth is the Lord's and the fullness thereof."

On the evening of the 13th, Dr. J. George Adami, Professor of Pathology at McGill University, gave an address. He, too, took as text, "Sins of the father," but delivered thereon no moral disquisition, but rather a scientific discourse, dealing with the inheritance of disease and the consequences of the sins of the father. Dr. Adami does not accept in its entirety the modern popular doctrine that acquired conditions are not inherited, and as a corollary that the germ cells are unaffected no matter what vicissitudes are undergone by the body at large, or rather perhaps by the body of the parent-at-large. He repudiates the doctrine that certain gross diseases do not directly injuriously affect offspring and stigmatises as specious, arguments that tend to show that the incidence of such diseases in children is due to diathesis, environment or maybe to a taint of degeneration which originated possibly generations back. Dr. Adami says that he is sufficiently old-fashioned to repudiate this new-fangled "Weismannism" and still holds to the belief that the sins so-called of the parents against the body, or at least, a very important series of such sins, do influence the progeny to his hurt.

First dealing with alcohol, Adami ranged himself on the side of those who contend that the children of an alcoholic parent or of alcoholic parents are prejudicially affected by their parent's or parents' habit. As for the inheritance of certain infections as tuberculosis and syphilis, Adami is of the opinion that the children of parent or parents suffering from these diseases are not merely of lowered vitality, more liable to succumb to childish ailments, but notably in the case of tuberculosis, exhibit a peculiar liability to succumb to the same parental disease. Furthermore, time and again the practitioner has observed a relationship between chronic or acute infection suffered by either parent and abortion, blighted ovum, still birth or monstrosity. Moreover, it is pointed out that inheritance of disease is far from being everything. From the point of view of eugenics, there are the terrible effects of congenital disease, and more especially of infections conveyed to the growing individual while in the womb or during parturition. When it is accepted that at least half of gynaecological practice is due to gonorrhœa and its results, that a large proportion of the cases of infantile blindness is of gonorrhœal origin, that as demonstrated by the Wassermann test, practically all cases of locomotor ataxia, and nearly all cases of general paralysis of the insane are of syphilitic origin; when it is known that most cases of multiple successive abortions are syphilitic, and it is recognised that the puny, miserable parodies of humanity, doomed in most instances to an early death, are too often the result of syphilitic disease in the parent; when the preventable ills that follow in the train of these venereal diseases are realised, Adami wholly agrees that the time has come when no longer should these matters be referred to by circumlocutions, when for the good of the coming generations open war should be waged against gonorrhœa and syphilis, and when above all our children, for their safety and welfare, should be instructed as to the dangers they must ward against, not merely on account of their own health and happiness, but for the sake of the generations yet unborn.

In concluding, the speaker praised Australia for her great work in this direction, noting that at the meeting of the Australian Medical Congress two years ago a resolution was passed to the effect that syphilis is responsible for an enormous amount of damage to

mankind, and that all preventive and remedial measures against it are worthy of the utmost consideration. The government of Victoria then took up the matter and Dr. Ham, its chief health officer, supervised a collective investigation with the aid of the medical profession of Melbourne. Dr. Conrad Hiller made official tests; syphilis was made a compulsory but impersonal notifiable disease for a period of twelve months within the Melbourne area. In all 5,500 cases were reported during this period. For four months at the end of the period all the cases visiting two of the hospital clinics, eye, ear, nose and throat cases, were tested. The results showed that out of a hospital population of 550, at least 13 per cent. were syphilitic. Adami made an earnest plea that Montreal, Toronto, Winnipeg, Edmonton, Calgary and Vancouver should follow the example set by Melbourne, so that with a knowledge of the prevalence of syphilis means should be adopted to eradicate a scourge which brings in its wake such hideous after-effects.

Among other important and instructive papers read were some on

MENTAL DISEASES AND THEIR TREATMENT.

Dr. Ryan of Kingston, Ontario, read a paper in which he traced the great improvement made in the treatment of the insane in Ontario during the past seven years, and in discussing the paper, Dr. Nicholls, of Edmonton, said that in the treatment of the insane Alberta was not even where Ontario was seven years ago, but where Ontario was twenty years ago.

Dr. H. A. McCallum of London, Ontario, was elected president elect, and London was selected as the next place of meeting. The following were elected members of the Executive Council of the Canadian Medical Association:—Drs. Whitland, Edmonton; Findlay, Montreal; Adami, Montreal; Halpenay, Winnipeg; Reeve, Toronto; McKechnie, Vancouver; Weld, Vancouver; Small, Ottawa; Kennedy, Macleod; Daniels, St. John, N.B.; Madre, Halifax; Archibald, Montreal; Primrose, Toronto; Conroy, Charlottetown; and Young, Saskatoon; Dr. H. G. MacKid, Calgary, as President of the Association, will be a member of the committee, *ex officio*.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

EDINBURGH POST-GRADUATE COURSE.—The post-graduate classes, which have just terminated, have this year been well attended and much appreciated by those frequenting them. The experiment which was tried for the first time this year, of having a continuous set of classes lasting from the middle of July to the end of September has been completely successful, some of the members of the class having remained for the three courses into which the two and a-half months' series is divided. In its original inception, the post-graduate course was intended mainly as a general course of instruction at which men might brush up their knowledge all round, and this ideal has been adhered to in the September course. Soon, however, it was found that a certain amount of specialisation was desirable, and the first result was to divide the September lectures and demonstrations into two sets, surgical and medical; then followed the August course of systematic instruction in the various departments of internal medicine, and finally, the July course of instruction in diseases of children. At present it would seem as though the more specialised and better organised courses on children's diseases, medicine proper and surgery, are more popular than the original general course, which includes classes on a variety of loosely strung together subjects, and it is probable that a better organisation of the non-surgical part of the September course would improve it. As it is, however, over a hundred graduates were attracted to Edinburgh this year, and of this number a large proportion came from over-seas.

THE INSURANCE ACT.—During the vacation months

the Insurance Act has been thrust into the background by holidays, and there is little to chronicle concerning it, so far as Scotland is concerned. Indirectly, however, it has provided competition with the sea serpent and the giant gooseberry of the silly season, in the shape of a mysterious advertisement in some of the local Edinburgh newspapers for a thousand motor cars. That remarkable body, the "National Insurance Medical Association" now invites tenders for 1,000 motor cars, chiefly 10-12 h.p., to be delivered in this country early in January. Further particulars can (says the advertisement) be obtained from Dr. Knight, the honorary organising secretary, 7, Chambers Street, Edinburgh. A reporter of the *Edinburgh Evening Dispatch*, however, could obtain none of the further particulars, and is obliged to confess that he left Dr. Knight's presence as wise as when he entered it. A call at the offices of the Scottish commission revealed the fact that nothing was known there of the National Insurance Medical Association—in short, the whole matter is wrapped up in mystery until the Knight of the Thousand Cars chooses to explain it.

INFECTIOUS DISEASES.

SMALL-POX IN KIRKCALDY.—About a fortnight ago small-pox broke out in Kirkcaldy, a notorious stronghold of anti-vaccination. A number of persons have been infected, and there have been several deaths. Strict precautions as to isolation, etc., are being enforced, and it is hoped that the epidemic will remain of limited extent. Free vaccination is being offered, and chicken-pox has for the time being been included among the notifiable diseases.

In Edinburgh there has been a somewhat widespread epidemic of diphtheria in one of the Eastern districts of the city; the outbreak is believed to be due to a milk infection.

In Dundee there has been a rather serious epidemic of scarlet fever, there being now nearly 120 cases under treatment, whereby the hospital accommodation is somewhat strained, as recently one of the largest pavilions in the hospital was given over to the treatment of tuberculosis. A large number of the patients are adults, and the disease is, happily, of a mild type. Up to the present there have been no deaths. The infection is not confined to any one district in the city, and its source has not been traced.

BELFAST.

PRESENTATION TO DR. J. T. CREERY.—The friends and patients of Dr. J. T. Creery, of Coleraine, Co. Antrim, took the occasion of his recovery from a motor accident, and the completion of thirty years of practice among them, to make him a handsome presentation last week. A committee, under the presidency of Mr. Hugh T. Barry, M.P., and representing all creeds and classes, was formed, and met with generous responses from all quarters. As a result of this, they handed to Dr. Creery last week a gold watch and chain and a handsome cheque. Dr. Creery, in thanking the donors, referred to the fact that he had been Dispensary Medical Officer and Officer of Health for twenty-eight years, and during all that time the most cordial relations had existed between him and the various boards connected with his work.

DOCTOR'S MOTOR ON THE FOOTPATH.—A curious case came before the magistrates in Belfast last week, when Dr. William Patton, of Grosvenor Street, was summoned by the Corporation for driving his motor car over the footpath. It appears that there is a gateway leading into the back of Dr. Patton's premises, where the garage is situated, but there is no corresponding break in the footpath, and for thirty years he and his predecessors have driven cars and motors through the gate and over the path. Suddenly the authorities seem to have concluded that this was dangerous to pedestrians, and issued the summons. It was proved, however, that this gateway had existed when the plan of the street was drawn up and passed by the Corporation, and the magistrate held that the bye-laws forbidding driving on the footpath could not

abrogate the right of every man to have free entry to and egress from his own premises, so the case was dismissed.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE POSITION OF DENTISTRY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In criticising my last letter which appeared on September 18th, "An Interested Observer" states, in your last issue, the case for his clients, the legally unqualified dental practitioners, clearly, plausibly and temperately; but this does not prevent him from quite unconsciously suppressing essential truths, suggesting much that is false, and casting unmerited aspersions upon past leaders of the dental profession. Throughout the whole practice of surgery, major and minor, ignorance is closely allied to cruelty and it is impossible for a mere mechanic, however honest and well intentioned, to avoid inflicting constant pain and injury when dealing with living tissues in disease. To be honest, a mechanical dentist, or maker of artificial teeth, should proclaim himself to be that and nothing more, and he ought to refer all cases in which diseased teeth are present to a qualified man, before attempting to apply artificial substitutes. The great majority of unqualified dentists not only undertake dental surgery, but they endeavour by more or less false pretences to make the public believe them to be educated dentists. The only guarantee of education and fitness to practise is given in a licence in Dental Surgery. A man so educated could not (as I said in my last letter), unless both a stupid and heartless rogue, deal with cases in the fashion usual with unqualified pretenders. These men all sacrifice vast numbers of teeth merely decayed, which could easily be saved by scientific treatment; and they constantly leave mouths in a septic state, hurtful to health and dangerous to life, because they do not recognise and are unable to treat conditions of disease easily to be dealt with by scientific dental surgery. The only way to get the requisite knowledge and training lies through pupilage for the dental diploma, and no one without such a qualification ought to be allowed to pretend to possess it. The legislature in late years has never proposed, and probably will never again attempt, to prevent unqualified men from practising in any department of medicine or surgery. What it has attempted, and what the penal sections of medical and dental Acts were specifically designed to do, was to enable the public to distinguish between legally qualified and unqualified practitioners, to prevent the latter from palming themselves off as educated and registered men. It is in this that the Acts have failed, and here that they need amendment. That such amendment could easily be made effective is proved by the case of the lawyers, so often illustrated in your columns. It is absolutely impossible for an unqualified or even for a qualified but unregistered man to practise as a solicitor under any pretence of any kind. He cannot with impunity assume any title or use any words implying in the remotest way that he is qualified.

With regard to the charge of snobbery which "An Interested Observer" seems to make against the "leaders of dentistry in the past" for their efforts to improve the status of their profession, these men showed throughout that they recognised the fact that dentistry must always remain an inferior, if not the most inferior, department of surgery, and that the title dentist, by which practitioners, however highly qualified, would always be known could never give the prestige attached to the title physician or surgeon. Dentistry has, however, been already in some degree, converted from a more or less disreputable trade into a respectable calling which a sensitive man need not feel shame in acknowledging; and as an individual's social position depends nowadays so much more on his personal qualities than upon the prestige of his

professional denomination, there need be no doubt dentistry, as it further advances, will prove sufficiently attractive to the classes from whom the great bulk of the medical profession is recruited. Dentistry is never likely to attract men ambitious for wealth, for worldly and professional distinction; and if it do not, it will not differ much from the whole medical profession. Everyone who proposes to join the ranks of the medical profession does so in the full knowledge that its members, whatever branch of practice they may take up, can have, except in the rarest instances, no hope that they will derive from the profession itself anything beyond a very modest social position, and a very moderate competency.

I am, Sir, yours truly,
A HOSPITAL DENTIST.

London, W., September 26th.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The fact would be farcical if it were not so tragical that the whole fabric of medical law laboriously worked out during fifty years by medical corporations and authorities and by Parliament, and embodied in several Acts has tumbled to the ground, and that the public and the profession still remain entirely unprotected against the wiles of the small army of cynical rascals who find a safe field for its operations in dentistry, as in many other departments of medical practice. The only law of the kind that remains valid is the Veterinary Act. Convictions for falsely pretending to be qualified under that Act have been easily obtained. Unqualified men have been fined for exhibiting a sign inscribed "Veterinary Forge," or for styling themselves "Feline and Canine Specialist." These convictions, although confirmed by the High Court, have not been submitted to the final arbitrament of the House of Lords. It is very probable that that august tribunal would overthrow them, as it has overthrown convictions under the Medical and Dental Acts. The drafting of each of these Acts is almost exactly similar, and yet the House of Lords holds that a man does not falsely pretend to be registered under the Dentists Act when he advertises with use of such words as "Dental Institute," "Dentistry" and "Dental Surgery." I enclose my card and

Am, Sir, yours truly,
A PROVINCIAL HOSPITAL DENTIST.

September 27th.

TUBERCULOSIS AND THE INSURANCE ACT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your article on Tuberculosis and the Insurance Act hits the right nail on the head. What we aim at is the prevention of tuberculosis, not its problematical cure. If the money which is to be spent on the erection of sanatoria had been allocated to local authorities for the purpose of destroying slumdom, then all thinking men would have agreed that it was a step in the right direction, and that we were treating causes, not symptoms. Suppose we have a case of incipient phthisis which is sent to a sanatorium, and is discharged therefrom as cured, which in many cases merely means that no manifestations of active mischief are present. This patient returns to a slum dwelling. How long will the "cure" last? Having obtained quiescence, we must maintain it by healthy habits and sanitary surroundings.

I should like to follow the histories of patients subsequent to their discharge from sanatoria and after they have been at home a month and returned to their usual daily routine. I fear that in many cases it would not prove a history of continued progress.

I should prefer to see £4,000 spent in pulling down insanitary dwelling houses rather than £20,000 spent in erecting an "up-to-date" sanatorium. The former would be an excellent advance in preventive medicine.

I am, Sir, yours truly,
S. J. Ross.

Bedford, September 25th, 1912.

THE GENERAL MEDICAL COUNCIL AND REGISTRATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I shall be greatly obliged for your help in reminding the members of the medical profession of the importance of keeping an address in the *Medical Register* which will form a safe channel of communication. The onus of notifying changes lies upon the practitioners themselves, and, though every possible effort is made to remind them of this and to trace them when touch has been lost, it is often impossible to get into communication with them. Representations have been made to the Registrar General, to the Board of Trade, and to other Government Departments, with the result that the Register is officially consulted far more often than it used to be. This affords protection to the public and to the profession alike, but any practitioner who has allowed his name to lapse from the Register may find himself temporarily much inconvenienced. I shall be glad to hear from anyone who has doubts as to the accuracy of his address, and all communications will be acknowledged.

I wish also to remind practitioners that the *Medical Register* is the only official publication, and that the entry of a name therein alone confers any legal privileges; it should not be confused with any of the directories which issue circulars every year.

I am, Sir, yours truly,
NORMAN C. KING,
Registrar.

General Council of Medical Education and Registration of the United Kingdom,
299, Oxford Street, London, W.
September 25th, 1912.

THE SPREAD OF SUPERSTITION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Under the above heading the *Times* of to-day, September 24th, publishes an interesting leader, an article with certain first-rate scientific and literary qualities of a kind such as to say the least are not common in other daily papers. The article opens with the statement that "it is good news that the police are about to do what they can to suppress fortune-telling and other practices of the same kind in London, and particularly that they will not in future allow fortune-tellers, palmists, crystal-gazers and clairvoyants to advertise in any way." A lucid examination of the psychology of the classes that provide the victims of the palmist and fortune-teller follows, and an explanation of the mischief to which they give rise; and it is pointed out that the impostor does not perhaps always know what harm he is doing. "He is not merely a symptom of a growing evil but also a cause of its increase, and should be suppressed by all possible means, and if the law at present is not stringent enough to suppress him it should be made more stringent." My object in calling attention to this article is to suggest that all its facts and arguments *mutatis mutandis* would apply to the trade in fraudulent cures and nostrums. To have a leading journal on our side in any public cause is to justify hope in success; and when the report of the Select Committee is published, we may surely hope that it will help in bringing about the alteration in the laws which in that direction have already been proved to be so urgently called for.

I am, Sir, yours truly,
London, W., September 24th. M.B., F.R.C.S.

[We refer to the subject of our correspondent's letter in our editorial columns.—ED. M.P. and C.]

OBITUARY.

SIR HERBERT ELLIS, K.C.B.

WE regret to announce the death of Sir Herbert Mackay Ellis, Hon. Physician to the King, which took place on the 30th ult. at Leavesden, The Common, Weybridge, after an illness extending over several weeks, at the age of 61. Sir Herbert Ellis was born in

1851, and was educated at St. George's Hospital, qualifying as L.R.C.P. and M.R.C.S. in 1873. He was elected an Honorary F.R.C.S. in 1906. He joined the Medical Department of the Navy in 1875, and served with the battalion of Royal Marine Artillery throughout the campaign in Egypt in 1882, being present at the engagements at Kassassin and Tel-el-Kebir. He was mentioned in despatches, promoted to Staff-Surgeon, and received the medal with clasp and the bronze star. In 1893 he was Fleet Surgeon on Board the *Victoria*, which was sunk in collision with the *Camperdown*. In 1904 Sir Herbert was appointed Inspector-General of Hospitals, and from that year to 1908 was Director-General of the Medical Department of the Navy. He was created a Knight Commander of the Order of the Bath in 1907. He was also J.P. for Carnarvonshire.

REVIEWS OF BOOKS.

CLINICAL IMMUNITY. (a)

DR. MATSON, in his preface to the English translation of Dr. Wolff-Eisner's little book, states as a reason for his task that he was struck by the clear and precise manner in which the author presents the difficult subject of immunity. His readers will agree with this judgment, and may add that the clearness and precision have lost nothing in the translator's rendering. It is not, however, merely his treatment of a difficult subject that makes Dr. Wolff-Eisner's work valuable, but the fact that he approaches it from a somewhat unfamiliar standpoint. Most discussions on immunity, as is but natural, are written from the point of view of the laboratory worker. In this book, however, we view it from the clinical aspect. As a consequence, the volume will be found interesting by those who are quite unacquainted with laboratory technique. Moreover, it can be read with understanding by any medical man of ordinary experience, even without any previous familiarity with the subject.

In the first place, Dr. Wolff-Eisner explains the meaning of the terms infection and virulence. He then briefly sketches the various theories of immunity. He tells us that he has been criticised for devoting so much space to the subject of hypersensitiveness. In this criticism we cannot join. "We are," he rightly says (p. vii.), "at the beginning of an era of clinical research based on the laws of hypersensitiveness." So true is this that already much of what he has written on the subject is out of date. He holds that hypersensitiveness is a vasomotor phenomenon, but this is only true in part. There are, as Auer has recently shown, many forms of anaphylaxis. A rabbit, for instance, dies of rigor of the heart-muscle, but the heart of the guinea-pig is unaffected, its death being due to stenosis of the finer air-passages of the lung. A dog suffers from neither of these conditions, but dies from a fall of blood-pressure. Nevertheless, though Dr. Wolff-Eisner's discussion may be already a little old-fashioned, it is of great value. The reader for whom he writes was much in need of a clear summary of our knowledge of the subject, and we know of none so clear and interesting as that provided here. It is of all the greater interest in that the author has been himself one of the pioneers in this work. The clinician will read with interest his arguments to show that such conditions as hay-fever, urticaria, and eclampsia are instances of hypersensitiveness.

Dr. Wolff-Eisner devotes more space to the subject of opsonins than is usual with foreign writers. He quarrels with Wright for differentiating opsonins and bacteriolysins, but he does not really come into grips with the question. The suggestion that "a distinction of this sort would make the subject extremely complicated and difficult to understand" (p. 109) is hardly adequate.

(a) "Clinical Immunity and Sero-Diagnosis." By A. Wolff-Eisner, M.D. Berlin. Translated by Ray W. Matson, M.D. Revised and Edited with a Special Introduction, by the Author. Demy 8vo., pp. xiv. and 181. London: Baillière, Tindall and Cox, 1912. Price 7s. 6d. net.

It is in his discussion of vaccine therapy that we find Dr. Wolff-Eisner at his weakest. He limits the use of vaccines to acute localised and to chronic infections. "The application of vaccines is contra-indicated in all infectious diseases in which 'bacterial poisons,' so-called, appear spontaneously in the circulation. This precludes all possibility of applying vaccine therapy in most acute infectious diseases." (p. 143.) This is a correct historical statement of the received opinion of six or seven years ago, but it is an opinion which has long been falsified by clinical experience. But perhaps the admission of this experience would "make the subject extremely complicated and difficult to understand."

Dr. Wolff-Eisner concludes with a discussion on chemo-therapy and a chapter on salvarsan. The fact that we have dwelt somewhat on his faults makes it necessary for us to repeat that the book is thoroughly interesting and suggestive, and in the main sound. The translator has on the whole done his work well, and, for a translation from the German, the text runs very easily. A few inelegancies, such as "bacilli emulsion," might have been avoided, and the translator has not always found the word sanctioned by usage, as when he speaks of "lateral chain" for "side-chain," and "vaccination therapy" for "vaccine therapy."

MEDICAL ELECTRICITY. (a)

THIS work originated in the author's belief that non-medicinal methods of therapeutics do not receive either in the medical curriculum or in medical practice the attention merited by their real value. Electricity is one of the methods to which he refers, and to a consideration of its uses in medicine and to the different ways of using it his book is devoted.

The work consists of seven sections. The first of these deals with the general subject of electricity, including Electro-statics, Electro-magnetism, and Electro-Magnetic Induction. The second section deals with Electro-Physiology, the third with Electro-Diagnosis, and Electro-Prognosis. In this section due attention is paid to the use of the cystoscope, the endoscope, and the various instruments for examining the nose, throat, ear and accessory cavities. The fourth section deals with General Electro-Therapeutics, the fifth with the methods of obtaining general and local effects by the indirect action of electricity, and the sixth with Special Electro-Therapeutics. In the last-named section the effects of electricity on the different organs of the body are discussed systematically. The seventh and last section deals with the application of the Röntgen rays in medicine.

We consider that the book is a valuable contribution to the literature of electricity, and deserves a place in the library of the medical man. It fulfils its objects, and may be consulted as a trustworthy guide. It is well and clearly written and contains a large number of excellent diagrams and other illustrations.

GYNÆCOLOGY. (b)

It is now many years since we first had the pleasure of seeing Dr. Lewers' work on the Diseases of Women, and we welcome with pleasure this new edition. It has been re-written and at the same time considerably enlarged by the addition of new matter and new illustrations.

The author naturally presents gynecological practice from a thoroughly English standpoint, and although we readily admit that the English standpoint has undergone very much change in the last five years or so, and that Dr. Lewers' work reflects this change,

(a) "Electricity: Its Medical and Surgical Applications, including Radiotherapy and Phototherapy." By Charles S. Potts, M.D. With a section on Electro-physiology, by H. C. Richards, Ph.D., Prof. of Mathematical Physics in Pennsylvania University, and a section on X-rays by H. K. Pancoast, M.D. Pp. vii. and 509. With 356 illustrations and six plates. London: J. and A. Churchill. 1912.

(b) "A Practical Textbook of the Diseases of Women." By Arthur H. N. Lewers, M.D. Lond., Senior Obstetric Physician to the London Hospital. Seventh Edition. Demy 8vo., Pp. xi. 540. With 258 illustrations, thirteen coloured Plates, five Plates in black and white, and a large number of illustrative Cases. London: H. K. Lewis. 1912. Price 12s. 6d. net.

still we cannot help thinking that there are many parts which might have been still further revised. Surely the chief objection to supra-vaginal amputation of the cervix in cervical cancer is not that it may cause contraction of the uterine outlet. Such a view is all the more strange when it follows an excellent description of Wertheim's operation, and when it is clear that the author considers the latter procedure the proper one. Similarly, although mention is made elsewhere of radical procedures for the cure of backward displacement of the uterus, no such treatment is even mentioned in the sections dealing with the treatment of this condition.

Various pessaries are illustrated and described as useful in the treatment of uterine prolapse, but the only operative procedure mentioned is colporrhaphy. The Staffordshire knot as a means of tying pedicles of ovarian tumours or the broad ligament below inflamed tubes is described, and various forms of pedicle needle are shown.

On the other hand, we thoroughly appreciate the description of Wertheim's operation for uterine cancer and the importance the author attaches to it; whilst amongst many good points in the book may be mentioned the large amount of clinical experience incorporated in it, the excellent micro-photographs—some reproduced untouched and some re-drawn, and the various coloured plates.

Much change has occurred in gynecological practice since Dr. Lewers' manual first saw the light, and we can truly say that there are few books of its age dealing with the same subject that so well deserve a place in the library of the student of the present time.

INSOMNIA. (a)

It is always a pleasure to read what Sir James Sawyer writes, and the present treatise forms no exception to the rule. We have had occasion previously to review the first edition of this helpful book, and now we gladly welcome the second edition. In the present volume we have before us the produce of the verbatim edition of the former book, together with many additions from the author's later experience.

The first clinical lecture on "The Causes of Insomnia" has undergone but little alteration. Additional material, "digested long and with care," has been assimilated into that portion which deals with treatment. Here Sir James Sawyer rightly points out that there is no "rule of thumb" cure, and gives a plain and very serious warning of the risks which attach to the administration of powerful hypnotic drugs. The habit of taking a hypnotic may very easily be formed by the insomniac, hence the patient should never be allowed to dose himself with potent sleep-producing drugs, but these should always be under the direct control of the physician. This is most sound and practical advice, but, on the other hand, we can only characterise as misleading the extravagant praise on p. 57 of *veronal*, which is mentioned on the authority of Richard Weiss, M.A., Ph.D., as having "acquired a world-wide reputation as the most harmless and trustworthy of all means for producing artificial sleep. . . ." We venture to think that this is not the verdict which has already been registered by a large number of medical practitioners and coroners. From practical experience we have seen so many untoward results follow its administration, even in moderate doses, that we prefer to class it with those hypnotics which have all been found to possess toxic effects. In a book which purports to be the outcome of the writer's practical experience we must also confess to a feeling of surprise that the opinion of a layman should be quoted on a matter which is purely clinical and not pharmacological.

Sir James Sawyer lays due stress upon the psychic causes of insomnia and gives most useful indications for treatment. One point which he makes is certainly worth remembering—viz., that "a hypnotic which may be fatal in an excessive dose may be fatal

(a) "Insomnia: Its Causes and Treatment." By Sir James Sawyer, M.D., F.R.C.P. Second edition Pp. 107. Birmingham: Cornish Bros. 1912. Price 2s. 6d. net

in an ordinary dose in a person who takes it habitually, by a kind of cumulative effect."

BLOOD-VESSEL SURGERY. (a)

It is right that the possibilities of blood-vessel surgery should be presented in book form, for up to the present the scattered publications on this subject in various periodicals have not given the ordinary surgeon a sufficiently adequate idea of methods and results. This volume deals mainly with the experimental side of the work, and gives but few details of possible applications in the surgery of man. As is well pointed out, the surgeon who undertakes to anastomose blood-vessels for the first time in a patient undertakes grave responsibility. Careful experiment is essential. The book deals first with the history of blood-vessel surgery, then with the *technique* of the various operations, and finally proceeds to treat of the results and applications. There is an interesting chapter on anæmia and hyperæmia, and a most suggestive one on alteration of the circulation in goitre. In the latter the writer concludes that when the circulation is reversed in the veins of a thyroid lobe, the ultimate result is a decrease in the size of that lobe. In histological structure it returns towards the normal, and the general symptoms tend to disappear. These results, together with a discussion on the effects of ligaturing the thyroid arteries are of particular interest. The transplantation of tissues is fully considered from the experimental side. In regard to the kidney, no permanently successful results in transplanting kidneys from one side to the other have been reported. We could wish for more details with reference to transfusion of blood and its *technique*, and a more extended discussion as to its possibilities in man; but the volume does what it sets out to do—namely, to give a *résumé* of the present condition of blood-vessel surgery in animals.

FIRST SIGNS OF INSANITY. (b)

THE purpose of this book will commend itself to many, and the publication of it is opportune, coming as it does at a time when public attention is more and more being directed towards the subject of insanity and the relation of insanity to the law. Nevertheless, it is not with developed insanity that this book has to deal, but with the early signs and symptoms by which the first signs of mental aberration may be detected. Already in this country there exists a mass of weak-mindedness for which little provision has been made, and the Mental Defect Bill and the Feeble-minded Control Bill before Parliament represent an attempt to remedy this state of affairs.

In many cases no treatment is adopted during the early stages of insanity—in fact, the condition is not recognised until the signs have already become well marked. The author's object is to point out that the majority of such cases are curable in this early stage, which is only "latent" because unrecognised, and that, provided the requisite care and attention during this period could be devoted to the patient, there would be no necessity for the stigma of lunacy to be incurred by admission to an asylum. Circumstances may be such that some place where the lunatic can be kept in safety is absolutely requisite, but it is not always necessary, says Dr. Hollander, to confine him in an asylum, though it is desirable in all cases to place him where he will have careful nursing and skilled medical attendance.

"It is the purpose of this book to show what insanity really is, how it can be prevented, and how it can be treated before it reaches the incurable stage." Whether the author has succeeded in the ambitious task which he has set himself is a matter about which there will be considerable diversity of opinion.

The book is written in a popular and attractive style and is printed in clear type.

MEDICAL LABORATORY METHODS AND TESTS. (a)

WE congratulate Dr. Herbert French on the appearance of the third edition of this popular handbook. In the present volume the author states that new methods and tests have been introduced and old ones modified. The primary object of the work, however, has been maintained, for it confines itself to chemical and microscopical methods that are of established value to medical men. As a small handbook for the medical laboratory it is, perhaps, unequalled, and Dr. French, in its publication, has earned the gratitude of both senior students and medical practitioners. It gives information in a condensed form, which is exceedingly useful for examination purposes in medicine, whilst as a book of easy reference for the medical man who prefers to do his own simple laboratory work it serves a good and useful purpose.

A SYSTEM OF SYPHILIS. (b)

VOL. VI. is the last of the series of the "System of Syphilis," and is written by officers of the R.A.M.C., by Medical Officers of the Navy, and one chapter by a Surgeon of the U.S. Navy. It deals, as may be supposed, with syphilis in the Navy and Army. We have had nothing but praise for the first five volumes, but unfortunately in this, the sixth, there pervades a tendency to consider venereal diseases from the moral point of view rather than from the medical and scientific side. It is a great pity, for in many of the chapters valuable information is given concerning the prevalence and treatment of syphilis in the Navy and Army. Even Sir A. Keogh, in his otherwise admirable introduction, falls into the error of saying "no invidious regulation discriminating against one sex only where both are equally guilty, if indeed the man be not often the more guilty of the two, and no discrimination between the rich and poor. . . ." What can all this have to do with the treatment and prevention of venereal disease? If the reader will turn to p. 40 he will find that the figures of syphilis in the British Army are only to be surpassed by those of the U.S. Army; the figures of the British Army are 20 per 1,000, the next on the descending scale being 16 in Austria. Lieut.-Col. C. H. Melville, the writer of this part, says a little further on, "In the first place, England and America are the only two great Countries where some form of Contagious Disease Act or other is not in force. . . ." The chapters by the same author on the History and Epidemiology of Syphilis are excellent, but we would recommend his conclusions with regard to preventive measures as a very good sermon for a military chaplain. The chapters on the Pathology and Microbiology of Syphilis by Captain L. W. Harrison are admirable and complete. The same may be said of Major C. E. Pollock's on the Clinical Course and Treatment of Syphilis in the Army, although no mention is made of "606" or "904." The following parts, dealing with syphilis in the U.S. and the British Navies, are interesting from the point of view of statistics. The last part, on Justus' test, by Staff-Surgeon W. P. Yetts, R.N., gives a short but clear account of this aid to diagnosis.

We may conclude by saying that all the medical points in this volume are admirably set forth, but we think it a pity that many of the authors have allowed themselves to wander into the domain of the clergyman. *Ne sutor ultra crepidam.*

MEDICAL NEWS IN BRIEF.

The French Congress of Surgery.

THE 25th annual meeting of the French Congress of Surgery will be held in Paris in October (7th to 12th).

(a) "Medical Laboratory Methods and Tests." By Herbert French, M.A., M.D.Oxon., F.R.C.P. Third edition, illustrated. Pp. 202. London: Baillière, Tindall and Cox. 1912. Price 5s. net.

(b) "A System of Syphilis." By D'Arcy Power and J. K. Murphy. Vol. VI. Pp. xix. and 514. Henry Frowde, Oxford University Press. Hodder and Stoughton.

under the presidency of Inspector-General E. Delorme. The following questions are on the programme of discussions:—(1) "Diagnosis and Treatment of Cicatricial Strictures of the Oesophagus," to be introduced by MM. Guisez, of Paris, and Moure, of Bordeaux; (2) "The Clinical Indications Supplied by Radiology in Surgical Affections of the Stomach and Intestine" to be introduced by MM. Bécèle, of Paris, and Mériel, of Toulouse; (3) "Coxa Vara: Its Relations with Fractures and Separations of the Epiphyses of the Upper End of the Femur," to be introduced by MM. Kirmisson, of Paris, and Froelich, of Nancy. During the Congress there will be an exhibition of surgical instruments, medical electrical appliances, dressings, etc., in the great hall of the Faculty of Medicine.

A Memorial to Lord Lister.

A MEMORIAL to the late Lord Lister is to be established at University College Hospital, and will be independent of any national or other movement that may be raised to the memory of the famous surgeon. It was in 1843 that Joseph Lister first became acquainted with the hospital and the college connected with it, taking the degree of Bachelor of Arts in the college in 1847, and then entering the hospital to complete his studies. A special committee has been formed, under the presidency of the Duke of Bedford, President of University College Hospital, and Sir John Tweedy, Consulting Ophthalmic Surgeon to the Institution, is to act as Hon. Treasurer of the fund. The exact nature of the tribute will be largely decided by the amount of the subscriptions received, but it has been suggested that either a bust or tablet should be placed in both the hospital and college.

Death under Stovaine.

An inquest was held last week at Lambeth on a patient named Harris, of Lavender Road, Battersea, who died after an injection of stovaine into the spinal cord at St. Thomas's Hospital, resulting in a verdict of death from misadventure, the jury adding that the anæsthetic was properly administered.

It was stated by Dr. C. M. Page, Assistant House Surgeon, who performed the operation, that Harris was a bad subject for chloroform or ether, and that was why the injection of stovaine was made. He told the Coroner that he had administered stovaine in 350 cases, and this was his first death. The stovaine was passed by a needle through the lower part of the spine, and it was practically a painless process. He explained that the number of deaths from failure of respiration after operations was about one in four or five hundred operations.

Another witness, Dr. R. S. Trevor, Pathologist at St. George's Hospital, said stovaine had been recognised as a suitable anæsthetic for the kind of operation performed on Harris. Ether would have been impossible in the case.

Gift of a Hospital to Chiswick.

THE Chiswick District Council received a letter last week inviting them to inspect a new General Hospital which has been built and equipped by a local resident who wishes to remain anonymous, and intimating that the hospital will be open for the reception of patients on Monday. The same benefactor some twelve months ago provided a Cottage Hospital for the district and has been maintaining it ever since.

The donor purchased Roxburgh House, Chiswick Mall. This will be used as an administrative block. The hospital stands in extensive grounds some thirty yards from the house, with which it is connected by means of a covered way. The wards for men and women are on opposite sides of the entrance, and will accommodate eight to ten persons each. At the top of the building is the children's ward, in which twelve children can be accommodated.

Medical School Scholarships.

THE following entrance scholarships have been awarded at St. Bartholomew's Hospital Medical School:—Entrance Scholarship in Arts, value £100, for one year, Geoffrey Bourne, Highgate School;

Jeaffreson Exhibition in Arts, value £50, for one year, C. M. Titterton, University College School; Senior Entrance Scholarship in Science, value £75, for one year, C. W. B. Littlejohn, New College, Oxford; Senior Entrance Scholarship in Science, value £75, for one year, C. R. A. Thacker, of Downing College, Cambridge; Junior Entrance Scholarship in Science, value £150, for one year, P. Nield Cook; Shuter Scholarship, value £50, to graduates in Arts of Cambridge, K. B. Belwood, of Pembroke College.

Children's Hospital, Temple Street, Dublin.

We are asked to supplement the notice of the Children's Hospital, Temple Street, Dublin, which appeared in our Educational Number (September 11th, p. 279), by stating that the hospital and convalescent home contain 100 beds, that in 1910, 1,164 intern patients were treated, and 17,521 extern. The Hon. Secretary is Dr. M. F. O'Hea.

St. Mary's Hospital Medical School.

THE following entrance scholarships of St. Mary's Hospital Medical School have been awarded at the September examination:—University Scholarships of 50 guineas each to C. N. Williams, University College, Cardiff; C. Hope Carlton, B.A., St. John's College, Oxford. Open Scholarship of £100, P. Hughes, St. Colomb's College. Palmer Scholarship of 25 guineas, T. Morris Davies, Caernarthen Grammar School. The Epsom College Scholarship has been awarded to C. L. Mason.

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature* or *Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eight, 12s. 6d. The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces. Small announcements of Practices, Assistances, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—May I ask you to grant me space to rectify a curious printer's error in my letter on the Position of Dentists, published last week. In the paragraph marked 2 you make me say, "A large, though a decreasing, proportion of registered men (qualified by examination) have no better qualification to practise than the . . . unregistered," etc. The words bracketed should, of course, read UNqualified by examination. Thanking you for this rectification.

I am, Sir, yours truly,

AN INTERESTED OBSERVER.

September 26th, 1912.

[We are, of course, pleased to insert the foregoing correction, especially as on reference to our correspondent's original letter we find the version in the *Medical Press* was literally and precisely that given in his manuscript. *Sic imprints honor est redivivus*.—ED. M.P. and C.]

THE LUXURY OF A BATH.

A CORRESPONDENT sends his experience to a lay contemporary when requiring a bath at Saint-Lo in Normandy, which possesses no public bathing establishment, in spite of its 12,000 inhabitants. Visitors, by a tacit agreement among the hotel-keepers, are accommodated with one litre of water a day for their ablutions, a quantity which usually suffices. Recently an enterprising traveller had the temerity to ask for a bath, and was eventually recommended to apply to the local hospital, where he hoped, as is the custom in some parts of Brittany, to be able to utilise a

bath-tub on payment of a small fee. The steward of the hospital was very sympathetic, but regretted he could do nothing himself, and advised the would-be bather to write a formal letter to the administration. This was done, but the visitor heard no more about the matter, and was obliged to go back to Paris unbathed. Shortly after his return he received a letter from the hospital couched in the following terms: "Monsieur C— will be exceptionally authorised to take a bath at the hospital, on condition that he can prove, by means of a doctor's prescription, that this medicament is necessary to his state of health."

ANNUAL REPORT OF THE N.S.P.C.C.

ACCORDING to the annual report of the National Society for the Prevention of Cruelty to Children, the number of complaints received during the year 1911-12 in England, Ireland and Wales was 54,118, this being the first time since the foundation of the Society that there has been a reported decrease in complaints. Involved in the cases were 156,637 children, or 1,569 less than last year. In the 52,371 cases found to be true 47,348 cases were dealt with as warnings; in 2,356 cases prosecutions were undertaken (of which 2,295 were successful); and 2,667 were otherwise dealt with. Of the 156,637 children affected 154,387 were related to the offenders; 146,533 were legitimate (1,495 being step-children); 7,554 were illegitimate; and 2,250 children were not related to the offenders. Of the above, 77,962 were boys and 78,675 were girls.

Meetings of the Societies, Lectures, &c.

FRIDAY, OCTOBER 1TH.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith Road, W.—8.30 p.m.): Opening Meeting of the Thirty-first Session. The President, Mr. G. P. Shuter, will deliver the Presidential Address, "The History of Nitrous Oxide Anæsthesia."

Appointments.

BORLAND, VYNNE, M.B., Ch.B.Glasg., Resident Medical Officer at the Children's Hospital, Sunderland.
CHITTY, HERBERT, M.B., M.S.Lond., F.R.C.S.Eng., Assistant Curator of the Pathological Museum of the University of Bristol.
COOMBS, HAROLD MARTIN McC., M.B., B.C.Cantab., L.R.C.P.Lond., M.R.C.S., House Physician at the Bedford County Hospital, Bedford.
DAVIES, C., M.B., Ch.B.Vict., House Surgeon at the Salford Hospital.
EDWARDS, D. R., L.R.C.P.Lond., M.R.C.S., Certifying Surgeon under the Factory and Workshop Acts for the Corwen District of the county of Merioneth.
HAY, R., M.B., Ch.B.Edin., Junior House Surgeon at the Royal Infirmary, Sunderland.
HOUSTON, T. H., M.B., Ch.B.Q.U.I., Casualty House Surgeon at the Salford Hospital.
KAY-MOUAT, J. R., M.B., Ch.B.Bristol, Demonstrator of Pathology in the University of Bristol.
LOW, HERBERT BRUCE, Ch.B., M.D.Edin., Honorary Assistant Physician to the Children's Hospital, Sunderland.
MORRIS, LEONARD NEWSOM, M.B., Ch.B.Bristol, L.R.C.P.Lond., M.R.C.S., Assistant Curator of the Pathological Museum at the University of Bristol.
ROBERTS, THOMAS, M.B., M.S.Edin., County Medical Officer of Health of Denbighshire.
RODGER, DOUGLAS, M.B., Ch.B.Vict., F.R.C.S.Edin., Ophthalmic Inspector of Schools to the Queensland Government.
WOOLF, A. D., M.D.Brux., L.R.C.P. and S.Edin. L.R.C.P. and S. Glasg., has been appointed Honorary Anæsthetist to the Leyton, Walthamstow and Wanstead Children's and General Hospital.

Bacancies.

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointment:—Borris (Co. Carlow).
The Hospital for Sick Children, Great Ormond Street, London, W.C.—An Assistant Casualty Medical Officer. Salary for six months £30, washing allowance £2 10s., with board and residence in the Hospital. Applications to the Secretary. (See advt.)
Ecclesall Bierlow Union.—Resident Assistant Medical Officer. Salary £200 per annum, with board, washing, and furnished apartments. Applications to J. E. Moulding, Clerk to the Guardians, Union Offices, "The Edge," Sheffield.
Hants County Asylum.—Third Assistant Medical Officer. Salary £200 per annum, with furnished apartments, board, washing, and attendance. Applications to the Visiting Committee, Hants County Asylum, Fareham.
Western Ophthalmic Hospital, Marylebone Road, W.—There will be several vacancies for Clinical Assistants on November 1st. Out-patients (yearly attendances 30,000) are seen at 1.30 on Monday, Tuesday, Thursday, and Friday, at 9 a.m. on Wednesday and Saturday, and at 5 p.m. on Friday. Applications to H. W. Burleigh, Honorary Secretary.
Portsmouth Borough Asylum.—Assistant Medical Officer. Salary £200 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.
Asylums Board, Isle of Man.—Assistant Medical Officer. Salary £170 per annum, with board, furnished quarters, and washing. Applications to Henry Cowin, Government Buildings, Douglas, Gordon Hospital, Vauxhall Bridge Road.—House Surgeon. Salary £50 per annum. Applications to C. St. Amory, Secretary. (See advt.)

Births.

GOULD.—On September 14th, at Castle Hill House, Shaftesbury, Dorset, the wife of Harold Utterton Gould, M.B., B.C., of a daughter.
KINLOCH.—On September 26, at "Sundridge," Lempford Road, St. Albans, the wife of R. Blair Kinloch, M.B., of a daughter.
RCH.—On September 28th, at St Portnan Mansions, W., the wife of Paul B. Roth, F.R.C.S., of a son, Leonard Harding, and a daughter, Vivien.
VOSPER.—On September 25th, at 112 Regent's Park Road, N.W., the wife of Percy Vosper, M.R.C.S., L.R.C.P., of a daughter.
WACE.—On September 27th, at Waleote, Winchester, the wife of Cyril Wace, F.R.C.S., of a son.
WHITE.—On September 2nd, at Mussoorie, U.P., India, the wife of Captain M. F. White, I.M.S., of a son.
WILSON.—On September 27th, at 18 College Crescent, Fitzjohn's Avenue, N.W., the wife of J. Clark Wilson, M.D., M.R.C.P., of a daughter.

Marriages.

PHILLIPS-DICKSON.—On September 19th, at Newchwang, North China, Walter Phillips, M.B., F.R.C.S.Eng., eldest son of the late Rev. J. G. Phillips, Damascus, and Mrs. Phillips, Mount Charles, Belfast, to Ethel Irene Katherine, youngest daughter of the late John Dickson, H.B.M. Consul, and Mrs. Dickson, Jerusalem. (By cable.)
WOODWARK-ROBINSON.—On September 26th, at St. Peter's, Cranley Gardens, Arthur Stanley Woodwark, M.B., M.R.C.P., son of the late George S. Woodwark, J.P., and of Mrs. Woodwark, Croylands, King's Lynn, to Hilda Mary, youngest daughter of R. A. Robinson, D.L., J.P., and Mrs. Robinson, Putney.

Deaths.

ELLIS.—On September 30th, at Leavesden, Weybridge, Inspector-General Sir Herbert Mackay Ellis, R.N., K.C.B., F.R.C.S., LL.D., J.P., Carnarvonshire, Honorary Physician to King Edward VII, and King George, Director-General of the Navy, 1904-1908, also of Rhylllech, Pwellieli, N. Wales, aged 61. Funeral at Weybridge Cemetery on Friday, October 4th, at 2.15 p.m.
GURDON.—On August 13th, suddenly, at Armadale, Melbourne, Ellen Anne, wife of Edwin Gourdon, M.D., and second daughter of the late John Randall, M.D., of London.
MASON.—On September 26th, suddenly, at Pontypool, Mon., Dr. S. Butler Mason, M.R.C.P.Edin, L.F.P.S.Glasg., L.S.A.
TERRY.—On September 25th, at Ashborne House, Wandsworth Road, S.W., William Frederick Terry, M.D., aged 77.

OPERATIONS—METROPOLITAN HOSPITALS.

WEDNESDAY.—St. Bartholomew's (1.30 p.m.), University College (2 p.m.), Royal Free (2 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. Thomas's (2 p.m.), London (2 p.m.), King's College (2 p.m.), St. George's (Ophthalmic, 1 p.m.), St. Mary's (2 p.m.), National Orthopaedic (10 a.m.), St. Peter's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Gt. Ormond Street, (9.30 a.m.), Gt. Northern Central (2.30 p.m.), Westminster (2 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), Cancer (2 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).
THURSDAY.—St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), University College (2 p.m.), Charing Cross (3 p.m.), St. George's (1 p.m.), London (2 p.m.), King's College (2 p.m.), Middlesex (1.30 p.m.), St. Mary's (2.30 p.m.), Soho Square (2 p.m.), North-West London (2 p.m.), Chelsea (2 p.m.), Great Northern Central (Gynaecological, 2.30 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), St. Mark's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).
FRIDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. George's (1 p.m.), King's College (2 p.m.), St. Mary's (2 p.m.), Ophthalmic (10 a.m.), Cancer (2 p.m.), Chelsea (2 p.m.), Great Northern Central (2.30 p.m.), West London (2.30 p.m.), London Throat (9.30 a.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), City Orthopaedic (2.30 p.m.), Soho Square (2 p.m.).
SATURDAY.—Royal Free (9 a.m.), London (2 p.m.), Middlesex (1.30 p.m.), St. Thomas's (2 p.m.), University College (9.15 a.m.), Charing Cross (2 p.m.), St. George's (1 p.m.), St. Mary's (1 p.m.) Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).
MONDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), St. George's (2 p.m.), St. Mary's (2.35 p.m.), Middlesex (1.30 p.m.), Westminster (2 p.m.), Chelsea (2 p.m.), Samaritan (Gynaecological, by Physicians, 2 p.m.), Soho Square (2 p.m.), Royal Orthopaedic (2 p.m.), City Orthopaedic (4 p.m.), Great Northern Central (2.30 p.m.), West London (2.30 p.m.), London Throat (9.30 a.m.), Royal Free (2 p.m.), Guy's (1.30 p.m.).
TUESDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.30 p.m.), Westminster (2 p.m.), West London (2.30 p.m.), University College (2 p.m.), St. George's (1 p.m.), St. Mary's (1 p.m.), St. Mark's (2.30 p.m.), Cancer (2 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), Royal Free (3 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), Soho Square (2 p.m.).

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX."

VOL. CXLV.

WEDNESDAY, OCTOBER 9, 1912.

No. 15.

NOTES AND COMMENTS.

Irish Insurance Politics. As a result of the decision of the meeting of the profession in Dublin, held recently, and reported at full in our SUPPLEMENT of last week, the medical officers of the various friendly societies operating in Dublin have given notice to their societies of the terms on which they are prepared to continue to act after the beginning of next year. The societies are proceeding to form a union so that they may decide on and pursue a common policy. Various schemes have been suggested. For instance, the societies may unite to form a central medical benefit committee which would be charged with the administration of medical benefits for all societies represented therein. It need hardly be said that such a scheme does not in itself call for opposition from the profession. Everything would depend on whether such a committee would be prepared to give terms agreeable to the profession. If not, matters would still be at a standstill. On the other hand, some of the societies speak of dispensing altogether with medical assistance, either in the way of medical benefits or of medical certificates as evidence of sickness in claiming sickness benefit. The Irish Insurance Commissioners indeed are instigating societies to rely on lay reports as evidence of sickness. This is generally regarded as "bluff," as without medical certificates the societies would be defenceless against malingering, and many of them would probably be bankrupt in a year. Out of somewhat heated controversy, however, a general feeling is growing that a settlement will be arrived at before January 1st, much on the lines suggested by the medical profession.

Doctors' Estates. In the columns headed "Wills Proved," which forms a weekly feature in the papers, it is not usual to find any record of the estates of deceased doctors, for the reason no doubt that the amounts in most cases are too paltry to be of public interest. Within the last week or so, however, a leading journal has thought fit to chronicle under a separate title the recently-proved wills of three deceased medical men. The average gross value of the three estates is a trifle over £3,000. These men had all enjoyed positions of great respectability if not of eminence, and one of them possessed qualifications of considerable distinction. It is possible that in publishing the paragraph in a prominent place our contemporary meant to hint at the reason why the entries of new students at the medical schools has fallen off this session—a fact commented on in the same issue. Every candidate for the profession ought by this time to be aware that the chances

are that he will be called upon for a life of great self-sacrifice. He will most likely have to die "with harness on his back"; if his health gives way he may be reduced to poverty, and unless endowed with private resources will probably in the end be unable to make any adequate provision for widow and family. If to these prospects are to be added the humiliation of mean and insulting treatment by the State and public bodies, the profession must lose its attractions to all save men of peculiar temperaments. At present, thanks to the high ethical quality of the great bulk of its votaries, medicine is a profession; it will not be good for the community if it become degraded to the level of a sordid trade.

Vaccination and the Birth Rate. It is possible that the remarks on the above subject which Dr. R. J. Ewart is reported to have uttered in his speech at the meeting of the Eugenic Education Society last week, may have been put forth merely as not very serious *obiter dicta*, and in any case the offence is not very serious; but it seems a pity that men of authority should on any occasion give out as fact to a popular audience, any statement not scientifically demonstrable. Referring to vaccination, Dr. Ewart is reported to have said that, at the beginning of the last century approximately one out of five children was killed by small-pox. Vaccination had allowed the survival of all these children to adult and reproductive life. Small-pox took off a certain type, and as a consequence we found that the present-day population was bigger, more blue-eyed, more intellectual, more moral, less fertile, and less susceptible to tuberculosis. Vaccination was one of the main factors responsible for the fall in the birth-rate. Excepting the first, everyone of these dogmatic statements is open to controversy, and there exists not the smallest evidence in support of the last. No authority in France, where the phenomenon has been longest visible and most closely watched, and no authority in this country, ascribes the fall in the birth-rate to any other cause than the voluntary interference of parents who have become skilled in the mechanical arts of preventing conception.

Insurance without Medical Examination. The scheme of life insurance without medical examination is based upon a profound knowledge of human nature. For some reason or other the average candidate for insurance, no matter how robust his frame may be seized with horrid fears in the presence of the examining physician. So dreaded is the ordeal, indeed, that it is not improbable that not

a few persons avoid insurance on that ground alone. So that any plan which avoids the medical examination is sure to cause a good many weak-kneed individuals to succumb to the wiles of the insurance agent. As a matter of fact, candidates who grasp at the shadow of non-medical examination find themselves in the long run burdened with its substance. The office substitute is a stringent list of questions, which the proposer is required to answer, and upon which a no less stringent scale of extra-risk premiums can be based. The actuary responsible for non-medical examinations is not likely to err on the side of leniency, as the proposer will probably find to his cost. As a matter of fact, the method is carried out at the expense of the public, which is seduced into accepting a costly substitute for legitimate medical services. The non-medical examination is widely advertised by the Sun Office, and it is a matter of some surprise that under the circumstances they are issuing to the medical profession a general appeal for support. It is impossible altogether to escape the reflection that this old-established office is thereby adding insult to injury.

**Bodies for
Research
Purposes.**

It is curious how the prejudice against the dissection of human bodies lingers in the public mind. It is now a century since the old scandals of "body snatching" culminated in the terrible crimes of Burke and Hare, but the subsequent introduction of the Anatomy Acts legalising the use of unclaimed pauper bodies by the medical schools has not sufficed to do away with the old prejudice. Only a few days ago it was announced that, with only two dissentients, the Chelmsford Board of Guardians passed a resolution in favour of sending the unclaimed bodies of paupers who die in the workhouse to the University School at Cambridge, for experimental purposes. One *Guardian* described the proposal as a scandal, but others, including two clergymen, said they would be willing to leave their own bodies to be used in a similar manner. The late Archdeacon Colley left his body by will to a medical school, and it has been accordingly conveyed to the Anatomical Department of the University of Birmingham. An objection of the kind must be based on sentimental grounds. It would be interesting to learn how the dissenting *Guardian* at Chelmsford would relish being operated upon by a surgeon who had never dissected the human body. As well might one trust a ship to a captain who had never been previously to sea and whose knowledge had been gained solely from books.

LEADING ARTICLES.

PROVISIONAL REGULATIONS UNDER THE INSURANCE ACT.

A FRESH phase of the dispute between the medical profession and the Government over the Insurance Act has been developed by the publication of the Provisional Regulations for Medical Benefits, drawn up by the Commissioners. The advance text of the document appears in full in the *British Medical Journal* of October 5th. First and foremost, there is no mention of the scale of remuneration, so that information is yet lacking on one vital point of the controversy. It is generally understood, however, that the Chancellor of the Exchequer will be able to offer terms that may be acceptable to the profession. In October last he informed the Joint

Advisory Committee that he would lay the matter before the Cabinet at the earliest possible date, and hoped to be in a position to make known their decision in the course of the week beginning October 14th. Clearly it will be out of the question for medical men to come to any definite conclusions in the absence of information as to scale of remuneration. Otherwise there is plenty of scope for discussion afforded by the regulations, and these will doubtless be carefully considered by the State Sickness Insurance Committee, upon whose findings the Council will proceed to draw up a report and ascertain the views of the medical profession. Such a referendum could hardly be completed and answers returned by the end of October, a date that leaves an ominously small space of time for further negotiations before the coming into force of the medical benefits in January of next year. It is not easy to say off-hand how far the Regulations are likely to meet the objections of medical men. A main feature appears to be the delegation of power to local committees. So far from pursuing what appears to be the eminently sound plan of enforcing a uniform income limit for insured persons, a permissive power of fixing such a limit. It really looks as if the Government were trying to evade the settlement of this important point, but doubtless the Council of the Association will deal with the matter exhaustively. Indeed, it appears fairly evident that the Commissioners have made no attempt to meet the cardinal objections advanced by the British Medical Association on behalf of the medical profession. The Commissioners seem to have acted on the general principle that all matters especially affecting the profession should be handed over as far as possible to the administrative mercies of the local or county insurance committees. During the next few weeks the Regulations will be duly considered and reported upon by the Association Council, and together with the proffered scale of remuneration, will form the subject of a momentous appeal to the Divisions. Perhaps the most encouraging feature of the present position is the tolerable certainty that Parliament will be asked by the Government to provide an increased contribution from the State to the insurance fund. In this connection we note that it has been announced, apparently on good authority, that Mr. Lloyd George will ask Parliament to grant a million pounds in order to pay an increased amount to the medical profession. Should that be the case it follows that the money will not be voted by the Commons unless a final agreement has been formally ratified with the British Medical Association, which in this instance is acting for the profession as a whole. At this juncture it is not remotely unlikely that the partial concession of the medical demands may turn the scale in favour of settlement, especially if there be an accompanying promise on the part of the Chancellor that a revision of the whole matter be placed in the hands of a Select Committee. These rumoured con-

cessions certainly offer a better prospect of satisfactory compromise than has been in sight for many months past. The time available for discussion, however, is growing parlously brief. In spite of his well-tried courage, we doubt if Mr. Lloyd George would care to face a general election in teeth of the active hostility of practically the whole profession. Nor can we believe that he seriously contemplates risking anything of the kind. We are told that he is yet on the threshold of his great social reforms. Surely it is a poor wisdom that would alienate the sympathies of the medical profession, a class of men who are intimately concerned in the prevention of disease and the prolongation of life, principles which lie at the foundation of all human progress.

THE POSITION OF DENTISTRY.—II.

THE correspondence so far evoked by our article on unqualified dentistry has been so far of a vigorous kind. Perhaps the point of most significance is the assertion that the attempt to rouse the dental profession to anything remotely resembling strong concerted action is—as one writer says—“like flogging a dead horse.” In that particular we fear the dentists fail along with their allies, the medical profession. The real meaning of this professional inertia is probably to be found in the absurd manner in which both branches of the profession stand in relation to the General Medical Council. That body takes their fees, regulates their course of study and examinations, enforces a domestic discipline which is lax as compared with that of the medical practitioner, and furnishes no help in the battle against unqualified dentists. Had the dentists a governing body worthy of the name, one that would discharge adequate defensive as well as disciplinary functions, their position would be greatly strengthened and the present *laissez faire* attitude would probably never have arisen. In fact, reform of the General Medical Council is required to protect the legitimate interests of the dentists, just as much as those of the medical profession, and, last, but not least, of the outside public. When the present Insurance Act troubles are over it may be hoped the medical profession will use their newly-found unity in endeavouring to provide the General Medical Council with a new constitution more in accordance with the spirit of modern times. It is certain that such a Council, elected upon a franchise really representative of the medical practitioners rather than of the State and of selfish corporations, would be likely to make strenuous efforts to lessen the volume of unqualified practice against which legally qualified practitioners have now to contend. Or, should they find the powers of the Council unequal to the discharge of the proper duties of such a body to its constituents, it would press for statutory reforms whereby the desired additions could be made. Meanwhile the position of the duly qualified dental surgeon is not altogether an enviable one,

chiefly by reason of the lack of protection against unqualified competition. Surely the State that exacted a long and costly course of education and examination in return for his diploma should protect him in the full enjoyment of the titular and other rights inherent to his status as a duly qualified practitioner. In later articles we hope to deal with the many important points involved in this discussion, for which purpose we hope to be favoured with the views of many leading dental surgeons in various parts of the United Kingdom. It is only by arousing a general interest that the matter is likely to be brought home to those authorities from whom the initiative must ultimately be sought. The journals devoted to the interests of the dental profession could hardly find a sounder objective for their energies than the reform of the General Medical Council.

CURRENT TOPICS.

The London Medical Exhibition.

THE Eighth London Medical Exhibition, organised by *The British and Colonial Druggist*, was held last week at the Royal Horticultural Hall, and it was a greater success than ever. The large number of medical practitioners who availed themselves of this unique opportunity for the leisurely inspection of every conceivable variety of medical and pharmaceutical novelty were amply rewarded for the time so spent. The practical exclusion of the general public served to confine the attendance strictly to the profession, the members of which could not fail to appreciate the excellence of the arrangements carried out by the organisers for their comfort. The practitioner who wishes to keep himself absolutely up to date can ill afford to miss the opportunity thus presented of seeing, in an outward and visible form, the advances made by the various ancillary sciences of medicine, and especially in pharmaceutical therapeutics. It is, indeed, a great achievement to collect together under one roof all the latest devices known to physiology, chemistry and pharmacy, in so far as these can minister to the special requirements of practical medicine and surgery, and yet this was done, and with conspicuous success, at this exhibition. It is gratifying, too, to note that the organisers have been recently appointed to undertake the complete control and management of the Exhibition to be held in London next year in connection with the 17th International Congress of Medicine, and we wish them all the success that they deserve in this most important enterprise.

Medical Treatment of London School Children.

THE Board of Education and the London County Council have now formulated the scheme, the inception of which was notified in these columns some time ago, for providing treatment for London school children. It comes into operation at once. Medical treatment centres are to be maintained by local committees of practitioners at Fulham, Hackney, Lewisham, Islington, Peckham, St. Pancras, Poplar, Blackfriars, Lower Sydenham, Norwood,

and Wandsworth. The Council will be responsible for control of the arrangements for supplying the centre with patients and for the supervision of the work generally. The centre will also be available for use in the medical inspection and re-examination of children. The classes of cases to be dealt with will include eye, ear, nose, and throat cases, ringworm cases for X-ray treatment, and minor ailments. The staff are to be selected by the Council from the local practitioners. Payment will be made of £50 a year for each practitioner or anaesthetist working one half-day a week, and a capitation payment of 2s. for eye, ear, nose and throat cases, 7s. for X-ray treatment of ringworm cases, and of 4d. for the treatment of minor ailments. A nurse will be provided to be in attendance while treatment is being given and for home visiting. The work will be under the supervision of the school medical officer of the Council. Under the arrangements for "following up" already in force all children should now receive treatment for defects disclosed at the inspection. We shall watch with sympathy the carrying out of this promising experiment, and report its progress in due course. It seems at least to promise fair treatment to the doctors, a necessary requirement for success.

Preservatives in Milk and Cream.

THE finally revised milk and cream regulations, which were described in these columns some months ago, came into force with the beginning of last week. The use of preservatives in milk is forbidden, and in cream restricted. This applies to condensed and dried milk, but as the term "preservative substance" does not include sugar, the traffic in condensed milk will not be interfered with. The regulations permit of the use of preservatives only in cream which contains 35 per cent. or more by weight of milk fat. One effect of this will in all probability be to raise the general standard, for the fact that a receptacle is labelled "preserved cream" will be direct evidence that the cream is up to the standard. The three preservatives not banned are boric acid, borax, and hydrogen peroxide. The proportions in which they may be used are not defined, the limit of 0.1 per cent. by weight at first laid down having been withdrawn. The Report of 1901 recommended that only boron preservatives should be allowed in cream, in an amount not exceeding 0.25 per cent., so that the final regulations do not follow precisely the recommendations of the committee. It is provided that all receptacles containing cream preserved with borax or boric acid shall be labelled conspicuously "preserved cream," and that the label shall bear a statement of the maximum amount of boric acid contained. Competition will serve the purpose of keeping down the percentage, while there are other means of checking the use of preservatives to such an extent as would be liable to endanger the public health. The amount of hydrogen peroxide used as a preservative need not be stated, but the label must bear the word "peroxide." These regulations may do some good, but evidently can effect nothing towards

prevention of the traffic in "dirty" and tuberculous milk and cream—a question of infinitely greater importance.

London Sanatoria.

AT the meeting of the Metropolitan Asylums Board on Saturday last, it was stated that the Board was willing to provide sanatoria accommodation and was prepared to place at the disposal of the authorities some 800 to 1,000 beds, the number corresponding to the requirements laid down by the Departmental Committee. A conference of representatives of Metropolitan boroughs had been held, twenty-four being represented, and they unanimously came to the conclusion that the Board was the proper authority to deal with the matter. From the point of view of London this is an extremely important question, and one which involves not only the better treatment of tuberculosis, but also the question of expenditure. In the 16th section of the Insurance Act, sub-section 8, there were the words "other than Poor-law authorities." That is the difficulty in which London is placed owing to its improper inclusion in the Act. Those who legislated never recognised what the government of London really is. London has at its disposal practically 1,000 beds for the treatment of tuberculosis cases in admirable institutions, under the administration of experts who have been for years devoting their time and attention to the subject, but London is debarred from accepting that advantage by this unfortunate clause in the Act, and the metropolis is therefore faced with the possibility of an enormously wasteful expenditure.

Retaliation.

WHEN the spirit of revenge fastens on a man much evil may result, but when a body of men are affected by its influence there is a tendency to senseless retaliation which does no good to those who are guilty of it, and no harm to the objects of their displeasure. A resolution of which notice was given at a recent meeting of the Guardians of the North Dublin Union is worth quoting in part because it is entirely and irrationally revengeful, and can in no way tend to produce any good. It ran: "That in consequence of the action of the Dublin Medical Committee in refusing medical attendance to members of friendly societies, or other such bodies, and excessive demands made by that committee, it is hereby directed that a notice be inserted in the newspapers and hung up in the various dispensaries intimating the hours of attendance of the doctors, also the name and address of each guardian and warden from whom tickets may be obtained." So far the object of the resolution is to harass the dispensary doctors by making them attend those members of friendly societies who can obtain red tickets. One can see some spark of reasoned retaliation in this, but we are absolutely at a loss to see the relation of the next clause either to doctors or the societies. It is proposed that all unclaimed bodies in the workhouse

should be buried and that none should be sent to the schools of anatomy. This would simply mean that students would be more ignorant of the groundwork of medicine and that the public would suffer in consequence. It would not stop the education of medical students, and if it did, it would only increase the power of existing members of the profession. The Guardians could do the Dublin practitioner no greater service than that of cutting off the supply of young doctors. Acting on the general principle of revenge without regard to the individual a proposal is made to break the contracts of all those doctors in the employment of the Guardians who are associated with the Medical Committee. The suggestion that those medical men who are in receipt of superannuation should be deprived of their livelihood if they have anything to do with the Medical Committee is too silly to call for comment.

The Disposal of Human Excreta.

WHEN we have grown accustomed to the use of a certain method of doing anything, we somehow begin to imagine that that method, if not ideal, is at any rate inevitable. The present method of removing human excreta—by water carriage—though it has only been in use about a hundred years, seems almost to have become part of the order of Nature. We are all used to it and the enormous capital sunk in the sewers will prevent any change for many years, and even then there will have to be some overwhelming advantage shown on the side of the innovation that will make its advent irresistible. The water-carriage system has undergone yearly improvements till it now seems very satisfactory, but really it has many objections that are discernible without much labour. Rivers and other watercourses are polluted. Each time a closet is flushed the use of some four or five gallons of water is entailed, and this steady use every day for each member of the community must represent an enormous annual sum in a large city. Moreover, valuable fertilising material is wasted, and in a land where the population is so greatly in excess of what the land can support this is especially serious. Agricultural experts state that the wheat crop could be increased by anything up to 100 per cent. by improvements in the method of tillage. To do this the farmer would require all available fertilising material, and the disposal of excreta for agricultural purposes should be an enormous gain. We have before now called attention to the unsatisfactory nature of the so-called sanitary arrangements on trains. The fæces are discharged through pipes which are invariably filthy and, from their design almost impossible to clean, direct on to the track, where they are scattered by the four winds of heaven to their ultimate rest, disseminating typhoid, dysentery and what-not far and wide. It is appalling to think of the results of the defæcation of a typhoid-carrier in one of the many trains that run alongside the rivers and reservoirs which supply us with drinking water.

The Bath.

THE bath as an instrument of treatment does not nowadays receive the attention it deserves. It is assumed, erroneously indeed, as has been shown, that we all take our morning tub, but beyond regulating this matter of routine few physicians take the trouble to prescribe to their patients the exact how, when, how much, and what sort of bath for each individual case. This is, perhaps, a reaction from the somewhat excessive prominence given to the bath in a previous generation. It is right, however, that the problem of the bath should be again put before use, and we are glad to find the task undertaken by Dr. Oscar Jennings, of Paris. In a neat booklet (*a*) he traces the history of the so-called Turkish bath from the earliest times, and discusses its hygienic and therapeutic applications. He himself for more than a quarter of a century, takes his bath every day, as a matter of hygiene, when circumstances permit, and he tells us of many distinguished Parisians who have the same habit, and who regard the bath as the safeguard of their health. It is curious how widespread throughout the world at one time was the system of hot baths. Nevertheless, the virtues of the Turkish bath had been forgotten, when, in 1850, Urquhart published his book on the subject and Dr. Barter opened his establishment at Blarney, the first of modern "hydros." Dr. Jennings is a firm believer in the virtues of the bath, not only in the case of the bodily ills often treated by its means, but in the case of various neuropathic or psychopathic conditions. His readers will find not only much to instruct, but much to entertain, them in his little book.

Individualism and Socialism in Medicine.

THE Insurance Act has brought to a head the feeling that something is amiss with the economics of medical practice. Doctors are overworked, their pay is inadequate, and this state of affairs is unhealthy for both profession and public. Two solutions are on the tapis. First, the individual practitioner, competing for his bread among a crowd of keen opponents, under conditions which tend more and more to commercialise his calling, and second, a national medical service, paid by the State, the members of which could give adequate time to each case without a haunting dread of not being able to pay for bread and butter. At first sight the "socialistic" scheme presents great and obvious attractions and the success of its practice among soldiers, criminals and paupers—who receive competent medical attendance as a right—seems to sweep away all objections. These analogies, however, are misleading. In the classes mentioned the doctor has all the forces of law and order to help him in carrying out his directions, and the patient with whom he has to deal differs greatly from the average of private practice. We all agree now that suggestion has a definite therapeutic

(a) "Le Bain Turco-Romain." Paris; Vigot Freres. 1912.

value, and confidence in the physician is a prime factor in producing the state of mind conducive to a successful issue. It will not do to plant a doctor in a district and bid all consult him, and without some such compulsion it is hard to see how a public service could be managed without unduly penalising the more popular men. Probably it is along the present individualistic lines that we shall find economic salvation. The present firm stand against the Insurance Act has efficiently checked a custom fraught with untold evil for a large section of the medical community. If the practitioners in each district can come to some agreement to avoid cut-throat competition the profession will soon right itself, and the survival of the fittest will continue to be the order of the day. It should not be past hoping for that eventually the successful man will be able to give himself the luxury of a little leisure, and the less fortunate brother receive at least a competency.

The Fallacy of Statistics.

A CURRENT newspaper correspondence on "Tuberculosis and the Milk Supply," although it has drawn communications from many authorities, has produced no facts new to medical readers. It has, however, elicited from Miss E. M. Elderton, of the Galton Laboratory, a letter which well deserves notice. The letter forcibly illustrates once more the fallacy of statistics. It suggests, again, how easily in the hands of an expert, when influenced by conscious or unconscious bias, statistics can be used effectually "to prove anything," whilst in many cases they can serve only to bewilder and mislead the simple reader. Miss Elderton suggests that it is fair to suppose that the sterilisation of milk should lessen the death-rate of infants (a) from digestive causes; (b) from tuberculous diseases; and (c) from infectious diseases. She then gives the statistics of Glasgow, and from these proves that in this city at any rate the sterilisation of the milk did not reduce the relative proportion of the infants dying from these three classes of diseases. She then turns to the much more ample data provided by the medical officer of health for Rochdale, Dr. Anderson. Here Miss Elderton deals only with non-breast-fed babies, and gives the percentage death-rates in the cases of each method of handling milk during 1909 and 1910 among infants using cow's milk in the first year of life. The statistics show that for both years the boiled-milk babies did much worse than the others. But in 1909 the "No treatment" babies were sensibly better and in 1910 sensibly worse than the sterilised. The total death-rate of babies fed with cow's milk in 1909 was 12.1 and in 1910 12.0 per cent. If we argue from 1910 we must advocate sterilisation, if we argue from 1909 we must say no treatment is the better. In 1909 13.3 per cent. of non-breast feeding mothers used no treatment of the milk. In 1910 only 4.2 per cent. of such mothers used no treatment. Miss Elderton points out that the "no treatment" mothers would surely be the careless mothers, the mothers of bad habits, whose infants have an excessive death-rate, and that this factor does not appear in statistics.

She urges that we are at present ignorant whether sterilisation is or is not an advantage and that no crude statistics which leave out of account the health and habits of parents will provide any final answer. The mother with bad health and bad habits will adopt no treatment as the easier course; the real problem is whether mothers of equally good health and equally careful habits have a higher or lower death-rate of their babies when using raw or sterilised milk.

PERSONAL.

SIR ANTHONY BOWLBY, C.M.G., opened the St. Mary's Nursing Home at Chiswick yesterday.

DR. W. H. PARKINSON has been appointed Assistant Medical Officer of Health to the School Medical Officer for Norfolk.

MR. FRANK R. SEAGER, L.R.C.P. and S. Edin., has been appointed Honorary Assistant Surgeon to the Warrington Infirmary.

DR. M. COHEN, Resident Medical Officer at the Hull Workhouse, has been appointed Senior Tuberculosis Officer to Hull.

DR. CHRISTIAN D. MAITLAND, of Aberdeen, has been accepted for foreign service by the Women's Mission of the United Free Church, and she sails for Rajputana on the 12th inst.

SIR JAMES GOODHART, Bart., M.D., LL.D., will deliver the Harveian Oration at the Royal College of Physicians of London on St. Luke's Day, October 18th, at 4 o'clock.

DR. FREDERICK TAYLOR will deliver the opening lecture at the Hunterian Society, London Institution, Finsbury Circus, to-night, at 9 p.m., taking for his subject "Sleepiness."

MR. JAMES LOCHHEAD, Edinburgh, has been appointed Colonial Surgeon at Gibraltar. Mr. Lochhead has held a number of surgical appointments, including that of Clinical Tutor in the Royal Infirmary.

DR. SEYMOUR TAYLOR will deliver the opening address at the West London Post-Graduate College, West London Hospital, Hammersmith, on October 14th, at 5 p.m., the subject being "Medical Education, Then and Now."

SIR J. ROSE BRADFORD, M.D., will deliver the opening address at the North-East London Clinical Society, Prince of Wales's Hospital, Tottenham, N., on Thursday, October 10th, at 4.15 p.m., the subject being "Science and the Practice of Medicine."

THE Directois of the Sick Children's Hospital, Edinburgh, have appointed Dr. Porter as Physician for Diseases of the Ear and Throat to the institution. The position is a new one, as hitherto ear and throat diseases have been dealt with in the ordinary medical and surgical wards and out-patient departments.

DR. B. P. WATSON, Edinburgh, has been offered, and has accepted, the post of Professor of Obstetrics in the University of Toronto. Dr. Watson is one of the most brilliant of the younger generation of obstetricians in Edinburgh, and while regretting his departure, his many friends congratulate him and his new University on the appointment.

A CLINICAL LECTURE

ON THE DECOMPRESSION OPERATION FOR CEREBELLAR TUMOUR.

By ADAMS A. McCONNELL, M.B., F.R.C.S.I.,

Assistant Surgeon, Richmond Hospital, Dublin.

PALLIATIVE measures are at once the glory and the reproach of surgery; the glory, because pronounced relief of symptoms may be obtained when all hope of radical cure has been abandoned; the reproach, because too many surgeons are inclined to perform palliative operations when the true interest of their patient lies in complete extirpation of the disease. Notwithstanding this, the surgery of the relief of symptoms is not practised to-day as much as it should be, and it is certainly not applied as early in the case as common humanity demands. We all remember patients suffering from malignant stricture of the œsophagus who have been subjected to slow starvation for months, before, moribund, they are afforded the relief consequent on a gastrostomy. Medical men are beginning to appreciate the benefits of early gastrostomy and early colostomy in inoperable tumours of the œsophagus and rectum respectively, and each of us has met with cases in which our palliative measures either proved curative or transformed an apparently inoperable cancer into an operable. The wider adoption of such operations as the two mentioned has depended largely on their intrinsic safety and on improved methods of their performance. When we consider the palliative operations for lesions of the brain and spinal cord we find that they are attended by a relatively high mortality, and that some experience in the surgery of these regions is necessary for their success. The principal cause of their limitation is, however, the general want of appreciation by the profession of the immediate benefits and the possibilities of cure which are their attendants. This case, to which I am about to direct your attention, is a good illustration of the truth of what I have just said.

The patient, Mrs. C. M., æt. 40, was admitted to the Whitworth Hospital, under the care of Dr. Travers Smith, who transferred her to the Richmond Hospital for surgical treatment. She complained of severe headache, impaired vision and increasing difficulty in using her right arm and leg. She stated that on several occasions when about her ordinary household duties, she was overcome by a sudden giddiness, in which the room seemed to whirl round her, and which made it impossible to stand on her feet. She usually vomited and momentarily lost consciousness during these attacks. Since admission to hospital she has had several attacks of vertigo, but as she has been confined to bed we can form no judgment of its effect on her equilibrium. The headache was frontal and of extreme severity; it came on at various hours during both day and night, and was only relieved by morphia. The chief cause of anxiety to the patient was the diminishing power of vision. When she came under observation the left eye was absolutely blind, but she could see fingers at a distance of one foot with the right. The right pupil was normal in size and reacted to light, whereas the left was moderately dilated and showed no reaction. There was some power of accommodation in the right eye, but none in the left. Ophthalmoscopic examination revealed the presence of double choked disc, worse on the left side. The

patient had had attacks of vomiting, which occurred without relation to the taking of food and without any premonitory nausea.

She walked with a shuffling, staggering gait, but did not show any tendency to fall. As a rule her course deviated to the left side, but on one or two occasions she walked towards the right. She could stand quite steadily with the heels together and the eyes closed. Examination of the motor mechanism elicited no loss of power of the right arm and leg, nor was there inco-ordination of any of the arm muscles. The knee-jerks were slightly increased on both sides. Ankle-clonus and Babinski's sign were absent. Kernig's sign was present on both sides. The head was held direct and did not incline to one side more than to the other. Tactile sensation was somewhat diminished over vague areas of the lower limb, and the power of localisation of sensations considerably less than normal.

The presence of double optic neuritis, the non-reacting pupil on the left side, and a ringing sound in the ear, designated by the patient "the dead bell," indicated the involvement of the second, third, and possibly the eighth cranial nerves, while the other cranial nerves were apparently normal. During her fourth week in hospital the patient became subject to tetanic-like seizures, in which the muscles were rigid, the teeth clenched, and the lips covered with froth. In each of these attacks she frequently sneezed. Each fit lasted for about two minutes, and then passed away leaving the patient in an exhausted condition. Her general mental state was depressed, and she lay in bed in a stuporose condition, from which she could be easily roused. She never spoke spontaneously. Pulse, temperature and respirations were normal.

There is nothing of note in the family history, nor is there any clear indication of syphilitic infection.

With regard to the diagnosis, as there were well-marked and obvious headache, vomiting, optic neuritis, and lowered mentality, which are the cardinal symptoms of intracranial tumour, such a general diagnosis was unavoidable. The localisation of a tumour inside the skull is, however, a much more difficult matter, for we must distinguish between those symptoms due to the local effects of the growth, and those due to involvement of other portions of the brain by the increased intracranial pressure. There were in this case, however, two symptoms, namely, vertigo and staggering, which pointed to the cerebellum as the site of the lesion. I need not mention the numerous disorders of various regions of the body that may produce vertigo. It is not on one symptom nor on two that we diagnose a lesion of the cerebellum, but on a definite symptom-complex which reveals intracranial compression with general indications of cerebellar affection.

In addition to vertigo and ataxia the early and rapid onset of optic neuritis and the startlingly sudden incidence of optic atrophy, as evidenced by failing powers of vision, directed our attention to the cerebellum, for except in intraventricular

growths there are few intracranial lesions which produce such rapid atrophy and loss of vision as is usual in cerebellar tumours. The tetanic-like seizures also suggested the cerebellum. They resembled in no respect the epileptic attacks due to lesions of the cortical motor centres; all the muscles were thrown into tonic contraction at once, there being no sign that any individual muscular group became affected first. There were no premonitory symptoms, either subjective or objective. The fact that the patient sneezed repeatedly in each attack may have indicated some irritation of the receptor nuclei of the fifth cranial nerve or of the expiratory centre in the medulla. Such involvement of these centres was, however, in all probability due to the increased pressure, and not to the local effects of the growth. The presence of tinnitus, expressed as the "dead bell" by the patient, gave us one more symptom of cerebellar involvement, for tinnitus is a relatively common subjective sensation in these cases, and has no relation to deafness, which may or may not be present. Having arrived at a diagnosis of cerebellar tumour our next duty was to find out whether the growth lay in the cerebellum itself, or simply occupied the sub-tentorial region of the cranial cavity. We excluded extra-cerebellar tumours chiefly from the absence of involvement of the sixth and seventh nerves, and from the fact that although tinnitus was present there was no deafness. The tumours of the cerebello-pontine angle almost constantly give signs of early involvement of these nerves, as one would expect from even a cursory examination of this region of the brain. From the point of view of treatment, this diagnosis was sufficient, for it is not of great import to localise a growth accurately in any given portion of the cerebellum. Owing, however, to the optic neuritis being more marked and the loss of sight more complete in the left eye than in the right; to the left pupil being dilated and fixed; and to the patient veering towards the left on attempting to walk, we came to the conclusion that the tumour lay inside the left cerebellar hemisphere.

It is usually extremely difficult to determine the nature of an intracranial growth, and as syphilitic lesions may produce all the cardinal symptoms of tumour, it is wise to put the patient on a course of mercury and iodide of potassium to see if any improvement takes place. Before this patient came under our observation she had received anti-syphilitic treatment for about six weeks without any improvement. Wassermann's reaction was negative. As a general rule, however, the multiplicity of symptoms, and their tendency to asymmetry, enables us to distinguish intracranial syphilitic lesions from true tumours. We must guard against allowing the patient to die from one disease, whilst we are attempting to diagnose another. Too often we find that the time employed in giving potassium iodide has allowed an operable cancer to become inoperable, or in the case of brain tumours it has been sufficient to kill the patient by cerebral compression before we are thoroughly satisfied that the disease is not syphilitic. It is in the highest degree irrational to leave a symptom untreated because we do not know its cause. It ought to be a rule in the treatment of cerebral syphilis to perform a decompressive operation as soon as the vision begins to be impaired. When a tumour is diagnosed, do not wait until the patient is comatose, but operate immediately. One can always relieve the compression and sometimes extirpate the tumour. When symptoms of compression are present do not attempt to relieve them by lumbar puncture, and do not employ this procedure as a diagnostic measure, because of the

danger of sudden relief of pressure in the spinal canal herniating the medulla through the foramen magnum and thus producing speedy death.

The dangers of cerebral decompression have been largely exaggerated, but no matter how considerable they may be, they weigh little in the scale against the certain and immediate relief afforded by the operation. If there be no clear indication of the site of the growth, or if the hope of removal has been abandoned, Cushing's operation under the temporal muscle is an extremely satisfactory procedure, and is equally efficient in cerebral and cerebellar growths. When, however, the tumour is localised in the cerebellum and when there is a possibility of removing it, a sub-tentorial decompression operation should be performed. As soon, therefore, as we obtained the patient's consent, we removed all the bone of the posterior cranial fossa on both sides, from the superior curved line above to the foramen magnum below, and from one mastoid process to the other. The dura was found tense and bulging to a degree which was discernible on both sides but more marked on the left. The occipital sinus being ligatured and divided, a crucial incision was made in the membrane and the posterior surface of the cerebellum exposed. Gentle palpation of the cerebellum revealed a relatively firm growth in the substance of the left hemisphere. Having relieved the compression and confirmed our diagnosis, we replaced the skin and muscle flaps and sutured them in position without drainage. The mass of cervical muscles forms a particularly good support for the protruding brain. The patient made an uneventful recovery. On the day after the operation she showed more interest in her surroundings than she had evinced at any period of her stay in hospital. On the second day she was sitting up and quite talkative. It is now fourteen days since the operation and there has been no recurrence of the headache, no vomiting or tetanic-like seizures. She is now able to move about the ward and there is a decided improvement in her gait, though she has still the tendency to deviate to the left. The condition of her left eye is not improved, though the reaction to light has returned in that pupil. She can see fingers with the right eye at a distance of two feet, and light appears considerably stronger than before the operation, but it is extremely questionable whether she will ever recover sufficient vision to enable her to perform ordinary household duties. Dr. Joyce reports that there is partial atrophy of both optic nerves, and that it is more marked on the left side.

The stitches were removed on the sixth day, and two days afterwards cerebro-spinal fluid began to flow freely from one point of the wound. For several days it discharged copiously but has now practically stopped. The sinus was painted with iodine at each dressing and at no time was there evidence of infection.

Much of the difficulty and danger of cerebellar decompression is due to the congestion of the veins of the head produced by ether. So free and so difficult to control is this general oozing in many cases that several deaths have been directly due to loss of blood, and many surgeons have therefore adopted chloroform. Since chloroform lowers the blood pressure to a considerable extent, and there is a great tendency to a sudden fall in blood pressure on opening the dura, this anæsthetic has decided disadvantages. For these reasons I welcomed the suggestion of my colleague, Mr. Crawford, that we should use hedonal as the anæsthetic. Mr. Crawford administered this drug into the cephalic vein and produced a very satisfactory anæsthesia. There was no general oozing of blood; we were enabled to place the

patient in the prone position, and the anæsthetist was altogether removed from the region of the operation. The fact that there was no post-operative vomiting or restlessness was of supreme importance. Judging from the anæsthesia produced by hedonal in this patient, and in another case in which I performed an osteoplastic exploratory operation for a cerebral abscess four days later, I am of opinion that this anæsthetic promises to be the safest, as it is certainly the most convenient for brain surgery. As far as I can ascertain this was the first operation performed under hedonal in Ireland, and I am greatly indebted to Mr. Crawford for administering this anæsthetic.

I am convinced that decompression operations are not performed nearly as often as they should be. Probably many practitioners are disinclined to advise them because of a formerly high mortality, and because of the transient nature of the relief afforded. With the modern instruments for brain surgery, and the increased accuracy of *technique* for which Cushing of Baltimore, and Frazier, of Philadelphia, are largely responsible, the operative dangers have become materially diminished within recent years. We must remember, however, that every day that compression lasts increases the risk of the operation, and that the chances of radical removal of the tumour depend on early attack. We do not wait for an ulcer of the stomach to perforate before we open the abdomen, nor should we wait until the patient is comatose before we look for a growth in the brain.

By operating in two stages on this patient, first the decompression, second the removal of the growth, we did not subject her to a very prolonged anæsthesia, and we certainly gave her a better chance of ultimate survival.

NOTE.—A *Clinical Lecture* by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Walter C. Stevenson, M.D., B.Ch., D.P.H., Assistant Surgeon, Stevens' Hospital, Surgeon Incorporated Orthopædic Hospital, Dublin. Subject: "Plaster of Paris in Surgery."

ORIGINAL PAPERS.

THE "PENNY SIGNS" IN PLEURISY AND ASCITES.

By M. BRELET, M.D.,

Of the Faculty of Medicine of Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

It is now many years since Professor Pitres, of Bordeaux, called attention to a new sign in pleurisy with effusion, based on the transmission of the sound obtained by tapping one coin on another, which he called the "signe du sou." It is as much as ever if this sign is even mentioned in textbooks, and it is but rarely taken advantage of, possibly because it emanated from a faculty far removed from the more famous temple of Æsculapius, situated on the banks of the Seine.

In a recent thesis, Dr. Janney has taken up the matter *de novo*, and makes it clear that Pitres' sign is often of the greatest assistance in the diagnosis of pleural effusion, often a matter of some delicacy. He also extends the usefulness of this sign to the detection of ascites.

To elicit Pitres' sign in a case of pleurisy with effusion, a coin is placed flat on the chest, in front, just below the nipple, and an assistant taps it with another coin, striking vertically. While this is being done the observer listens over the back and side of the thorax. If the interior of the thoracic cavity be occupied by a homogeneous medium,

either solid or liquid, which conducts sound more perfectly than normal pulmonary tissue, the percussion sound is audible as a clear ringing silvery vibration. The "penny sign" is, therefore, not pathognomonic of pleural effusion, but as massive indurations of the pulmonary parenchyma are much more uncommon than pleural effusions this sign, taken in conjunction with the more or less complete series of other signs and symptoms, will, in most instances, indicate the existence of a liquid effusion into the pleural cavity. Jacobson and Dianelopoulo, in a communication published last year, state that they regard the "penny sign" as the best sign of extensive pleural effusion, and Professor Achard concludes that "this sign deserves to be employed methodically and as a matter of routine, and that its simplicity particularly commends it to the practitioner."

The laws of the transmission of sound are, of course, the same in the abdomen as in the thorax, so that Lesieur and Rebattu have extended its use to the diagnosis of the presence of ascitic fluid in the peritoneum. The patient lies on his back and a pillow is placed under the pelvis, in order to facilitate auscultation and percussion of the dependent parts. Then, in order to ascertain the mobility of the fluid, the patient is made to turn on his side, or to sit up. An assistant applies a coin over the abdominal wall, in the lumbar region, or the iliac fossa, which he holds firmly by means of two fingers. With the other coin in his right hand he taps perpendicularly on the coin, graduating the shock to the thickness of tissue to be penetrated, beginning gently and steadily increasing in strength. During this time the observer applies his stethoscope over the abdomen, at a spot exactly opposite to the position of the coin. The limit of the effusion can be determined by changing the relative positions of the coin and the stethoscope. Dr. Janney gives the results obtained by him in a number of pathological states.

Normal Abdomen.—One hears a prolonged vibrating sound, more or less resembling the metallic sound described by Trousseau in pneumothorax. Sometimes in the lower parts of the abdominal cavity the sound becomes a little muffled (wooden sound), retaining, however, in part, its metallic *timbre*. The results correspond to the theoretical data given by Pitres. When between the point percussed and the point auscultated there exists a cavity filled with gas the transmitted sound is vibrating and reinforced (the metallic sound). If there be a layer of spongy areolar tissue the transmitted sound is dull (wooden), but never in a normal abdomen do we get a silvery clear sound, the "penny sign" is consequently negative.

In obesity the "penny sign" is always negative, one gets a sound like that of bronze. In meteorism and tympanism the results are the same.

In ascites, of which the author gives 35 instances, the result in 31 cases was very obviously positive, that is to say, they heard a clear, silvery sound. In four cases it was doubtful or faintly positive. It follows, therefore, that when there is a mass of fluid between the two points the transmitted sound is clear and silvery in tone. With regard to the cases in which the result was doubtful it is to be noted that in one of them the ascites was very abundant and under great pressure, so that possibly the heightened tension hindered the transmission of the sound. In the other instances it may be that peritoneal adhesions fixed the loops of intestine, locking up the effusion into compartments and thus interfering with the production of the "penny sign." In most of these cases it was found possible, by shifting the point of percussion and auscultation, to demonstrate the limits of the effusion.

We must, however, bear in mind that the existence of any homogeneous mass between the points of percussion and auscultation yields the same result as a layer of liquid, so that the "penny sign" may be positive in presence of uterine fibroids, in pregnancy (four cases), and also in ovarian cysts.

To sum up, the "penny sign" is not pathognomonic of ascites, it merely shows the presence in the abdomen of a homogeneous medium, either liquid or solid, in an uninterrupted layer. Therefore, when the sign is positive we still have to differentiate ascites from fibroid or pregnancy, and, as a rule, this can be done by noting that, in the first case, in order to obtain the silvery tone, we have to percuss in the *lower* parts of the abdomen, whereas, in fibroma, or pregnancy, the sign is perceived when percussing over the epigastrium. The "penny sign" only having proved fallacious in four instances out of 35, Janney considers it as an excellent sign of ascites, deserving of a foremost place in the methodical exploration of this condition.

EYE-STRAIN, AND ITS DETECTION IN PRACTICE.

By SYDNEY STEPHENSON, D.O. Oxon.

"EYE-STRAIN," a convenient modern expression, may be taken as meaning that the eyes cannot be used, as they should be in a state of health, without entailing a strain upon the muscles, intrinsic or extrinsic, of the eye, which in its turn betrays its presence by local or general discomfort. It is a matter of common knowledge that this strain is more likely to show itself among the cultivated than the non-cultivated members of society, so that the small error of refraction that would almost certainly pass without notice in an agricultural labourer might give rise to serious discomfort in a hard-worked literary man. For a similar reason, symptoms are more likely to be met with in women and children than in grown-up persons. Finally, the so-called "neuropathic temperament" is without doubt a most important factor in determining the symptom-complex of eye-strain.

That many a chronic "headache" or "neuralgia" is due to eye-strain is nowadays admitted by everybody, although there need be *neither pain nor discomfort in the eye itself*. But when we come to a multitude of other functional disorders, chief among which are chorea and epilepsy, there is no such unanimity of opinion, even among those well qualified to judge. On the one hand stand certain writers, in particular Dr. George M. Gould (*a*), now of Ithaca, U.S.A., who would trace almost any and every affection of the nervous system to eye-strain, while others see in the relief of this or that symptom by weak glasses merely an evidence of suggestion and nothing more. Does not the truth, as usual, lie somewhere between these two schools of thought?

In reference to this point, some years ago Dr. Lucien Howe (*b*), of Buffalo, N.Y., endeavoured to find out how often such conditions as tuberculosis, anorexia, denutrition, constipation, dyspepsia, chorea, epilepsy, insomnia, and so forth were due to eye-strain. To that end he issued a comprehensive circular letter to 208 medical men, including in the number 162 members of the American Ophthalmological Society. One hundred and five replies were received, but of these 34 gave no figures whatever. Seventy-one reported (at least, approximately), their total clinical experience, but of that number twenty-four alone sent complete replies of such a nature that they could properly form a part of a table of statistics. Dr. Howe estimated that the returns received from the twenty-four contributors covered some 350,000 cases in which eye-strain was a factor. Twenty of these observers had never seen a single case in which the unusual conditions mentioned in the circular were due to eye-strain. On the other hand, four of the observers had noted, apparently as the result of eye-strain, the following conditions—chorea (one case), epilepsy (five cases), and insomnia (twelve cases).

In view of the foregoing figures, Dr. Howe was amply justified when he concluded:—"This large experience shows beyond question that in the future it will be impossible for anyone to repeat the claim that these reflexes or conditions or any of a similar kind are considered by most American ophthalmologists to be the result of eye-strain. This is simply the assumption of a few enthusiasts."

The detection of eye-strain, even by the medical man, is by no means always the simple matter that it appears to be at first sight.

Matters are simplified if a patient complains of pain at the back of the eyes, or if the latter become red and watery and uncomfortable after use, or show such obvious signs of ill-health as redness of the edges of the eyelids or repeated styes.

It is most important to bear in mind that the sufferers seldom complain of any defect in vision. Indeed, nothing is commoner, when a suggestion is made that eye-strain may be the cause of their symptoms, than for them to remark, not without a touch of indignation, "My eyes cannot be at fault, as I have splendid sight." And so, in truth, they often have. But the question is: How do they obtain it; at the expense of a strain upon their eyes or otherwise? Every ophthalmic surgeon recognises that, other things being equal, the tiny error of refraction, and not the larger one, is usually responsible for the symptoms of eye-strain. A patient affected with, say, a pronounced degree of hyperopic astigmatism has never enjoyed good sight at a distance, and has learned by experience that by no effort can he obtain sharp images. Hence his complaint is not of "neuralgic headaches" or of "brain-fag," and so forth, but of defective sight. His case is very different from that of a patient affected with a quarter of a dioptré or even less of hyperopic astigmatism, an amount that can be readily compensated by a continual and unequal contraction of the ciliary muscle. Such a patient may have sight that is actually better than normal, but in a neuropathic subject the strain involved may result in headache, eyeache, "neuralgia," or the thousand and one ills that may be the outcome of eye-strain.

It must be borne in mind that the conditions of clear sight in such a patient imply a constant strain upon the ciliary muscle, which never gets a rest, except when the patient is asleep. In an emmetrope, on the other hand, the eye is at rest when looking at distant objects, since the images are focussed upon the retina without the intermediation of the muscle itself. To quote the graphic words of Dr. Leonard Williams:—"The patient sees well, but in the majority of cases he does so at a cost which, physiologically speaking, he cannot afford to pay. He lives well up to the limit of his nervous income, and any slight unexpected attack will very readily project him into bankruptcy. It is when he has reached this state that he appeals to his doctor to be relieved of a headache or an attack of neuralgia." ("Minor Maladies and Their Treatment," 1906, p. 139.)

From what has been said, then, it is clear that the mere test of the relative visual acuity (in plain language, the "sight"), as carried out in the usual way with Snellen's distance types, has scant diagnostic value in these cases. In point of fact, the patient who reads the normal line when tested by those means is likely to be the very one whose general symptoms are in reality due to eye-strain, and it would be an error of judgment on the part of a practitioner to assure such a patient that his eyes were not at fault.

Again, there is the further consideration that myopic conditions, which impair the visual acuity to a relatively great extent, are not often the cause of eye-strain. Yet these are the very errors likely to be detected by the use of the Snellen types.

There is one condition in which the distance types may give us a valuable clue as to the nature of the underlying symptoms—to wit, when there is an inequality between the sight of the two eyes. It is well known that symptoms of discomfort are more likely to come on under those circumstances.

Somewhat similar considerations apply to the estimation of the muscular balance by means of the Maddox compound rods or in other ways, as by the so-called "cover-test." The primary difficulty here

is to determine the normal. An imperfect muscular balance that would produce symptoms of discomfort in one individual, may exist in another without producing any symptoms whatever. The personal factor is just as important here as in the case of refractive errors. Besides, these functional anomalies, conveniently grouped, as everybody knows, under the name "Heterophoria," are intimately bound up with errors of refraction; so much so, indeed, that to-day some good authorities maintain that muscular imbalance comes from errors of refraction, and that persistent wear of correcting glasses will ultimately dissipate all the symptoms. (c)

It seems clear, therefore, that in order to diagnose eye-strain, something more is needed than the mere testing of sight by the Snellen types and the estimation of muscular balance by the Maddox rods.

A valuable clue is often afforded by the history. A patient sometimes volunteers the statement that his headache or what not is induced, or at all events made worse, by using his eyes, and contrariwise relieved by rest. A direct question will frequently bring out the same point. Especially characteristic are cases where patients complain that headaches are brought on by riding in the street cars or by visiting picture galleries or cinematograph shows, the so-called "panorama headache" of the Americans. Whenever a patient who is suffering from headache, "neuralgia," giddiness, loss of energy, insomnia, or so forth makes such a statement, we should at all events be placed upon our guard, and think first of the case being one of eye-strain.

Speaking generally, the pain due to over-taxed eyes is in the frontal region, often immediately over one orbit or both (Head). Thence it tends, when severe, to radiate into the temples, or, for that matter, to become general. The ocular headache is generally most marked, as might be expected, towards the close of the working day, although in a recent communication by Mr. Percy Flemming (d) stress is laid upon the diagnostic importance of a "morning headache." The patient wakes with the headache, which improves after breakfast, and may be absent during the day if the eyes are not much used, but will be increased or brought about by using the eyes for near work. Dr. R. W. Doyne (e), on the contrary, says: "It is very rare for ocular headache to persist after sleep, and the fact that it does so throws grave doubts upon the question whether the eyes are the cause of headache in that particular instance." Dr. James Hinshelwood (f), again, states categorically that ocular headaches are generally absent in the mornings, an observation that agrees with my own experience. Under any circumstances, however, it would probably be unwise to lay much, if any, stress upon the question of "morning headache" as a diagnostic feature. It is, I think, going altogether too far to say, as Mr. Flemming does, that unless a headache is frontal or situated above each orbit, and is present on awaking in the morning, "a surgeon should hesitate about correcting a half or quarter D of hypermetropia or astigmatism." A more rational attitude, as it seems to me, is that adopted by Dr. Leonard Williams in his useful book on "Minor Maladies and Their Treatment" (1906). That accomplished physician writes:—"Neither the distribution of the neuralgia (except that it is generally cranial) nor the type of the headache, affords any indication that it is the eyes which are at fault, so that it is all the more important to keep constantly reminding ourselves of the now well-established fact that where either of these symptoms cannot be traced to any obvious cause, eye strain is, in all probability, the main factor in their production" (p. 140).

It is unfortunate that, by the very nature of things, we are often precluded from adopting the most certain test at our disposal as to the ocular origin of this or that symptom—namely, by the application to the patient's eyes of a weak solution of atropine sulphate. By paralysing the ciliary muscle, that drug, of course, places the eyes temporarily at rest, and if under its continued use a chronic headache, or "neuralgia," or what not, disappears, we are justified in concluding that the symptom was due to eye-strain. It is unfortunate, again, that in myopia, where the remedy causes

a minimum of discomfort, manifestations of eye-strain should be relatively uncommon, and that in hyperopia, where the manifestations of eye-strain are common, atropine gives rise to maximum discomfort. In that condition, when the eyes are under the influence of atropine, reading becomes, of course, out of the question, while even distant sight is blurred in direct correspondence with the degree of error that exists. Still, I repeat that the most valuable and conclusive proof as to the ocular origin of this or that symptom is to be found in the use of a solution of atropine for a few days. I may add that the strength of the solution need never exceed one grain of the sulphate salt to one ounce of sterile water.

When we come to the detection of an error of refraction that underlies a given case of eye-strain, too much stress can hardly be laid upon the fact that the error must be diagnosed and estimated with the eyes under the full influence of a cycloplegic, such as atropine, scopolamine, or homatropine. In these cases a mere appropriation to the exact error is not enough, as it often is in hospital patients suffering from the grosser errors. If good is to accrue, the error must be worked out precisely, which, as a rule, can be done only by an ophthalmic surgeon, equipped with modern instruments, and endowed with the skill and provided with the time to use them properly. The point is all-important. As Dr. James Hinshelwood (f) has remarked, another reason why eye-strain as a cause of symptoms is often overlooked is because the patient is already wearing glasses, and has derived little or no benefit from them. There are many sufferers from eye-strain going about to-day wearing glasses which fail to give them relief, or who, after a trial of such inefficient glasses, have become convinced that their symptoms are in no wise connected with their eyes. Yet under a more careful system of examination these patients could probably obtain relief.

The days are now happily past when ophthalmic surgeons in this country disdained to correct anything less than one dioptre of astigmatism unless sight were impaired. The general teaching but a few years ago may be gathered by the following extract from a widely-read and popular English text-book of ophthalmology, the sixth edition of which was published in 1897:—"It is not usually necessary to correct astigmatism of less than 1 D; but exceptions to this rule are not uncommon, some patients deriving marked benefit from the correction of lower grades." A conscientious practitioner nowadays is careful to detect and to correct the smallest amount he can find, when reflex neuroses are present, and he often has his reward in the relief obtained by his patients. Speaking for myself, some of my most gratifying results have been obtained where amounts as low as 0.25 or 0.12 D of astigmatism have been neutralised by glasses. Another point that seems to me well-nigh essential to success in most cases of eye-strain is the constant use of the correcting glasses. Patients should have the difference between "rest glasses," on the one hand, and "sight glasses," on the other, very clearly explained to them, and they will not then discard as useless a pair of glasses given for the relief of eye-strain because at a distance they "can see better without than with them." To obtain the co-operation of the patient is to take a long step towards success in the treatment of the case.

- (f) Hinshelwood, James. "Lancet," February 13th, 1911.

MR. G. A. WRIGHT, F.R.C.S., of Manchester, who is about to retire to the South of England, was entertained the other day to luncheon by the Executive Committee of Lister House, a hostel for medical students which he was instrumental in founding, in conjunction with Mr. Joseph Bell and Dr. F. Tylecote.

MEDICAL MEN AND CONTRACT PRACTICE. (a)

BY HAROLD B. GRIMSDALE, B.Ch.CAMB.,
F.R.C.S.ENG.,

Ophthalmic Surgeon to St. George's Hospital; Surgeon to the Royal Westminster Ophthalmic Hospital, &c.

GENTLEMEN,—It is reported—I don't know whether the story is authentic—that the great Abernethy, on some occasion similar to the present, greeted the newcomers as follows:—

“Good God, gentlemen; what is to become of you all?”

His exclamation showed that, even 100 years ago, the medical profession, in the opinion of one of its leaders, was over full, and not over paid. Unfortunately, perhaps, there is no record available to show what became of his audience; we will assume that they all qualified and lived happily ever after. Certainly his words cannot have been taken much to heart, for the number of medical men in the United Kingdom has increased and gone on increasing ever since.

You, the newcomers, are entering the profession at a moment when it is engaged in a struggle for life. The course of study is more difficult and prolonged, the methods of examination necessary to successful diagnosis and treatment are more laborious and costly, and the competition keener than ever before. Modern methods have advanced so far, that it is not possible for the general practitioner, however energetic, however capable, to carry out for himself all the investigations needful for diagnosis in certain cases; and medicine is, at last, we hope, becoming a science as well as an art.

It has been a strange spectacle which has been presented to the world during the months that have passed since the passage of the Insurance Act—a spectacle without parallel in the history of medicine. We have seen the united profession—united more completely than ever before—standing firm together in their resistance to an Act which professes to carry out the work which is specially the province of the profession, viz.: to provide benefits which it is the boast of our profession to give freely to all, very often without thought of reward, seldom with an adequate one. It is indeed a strange spectacle, and the profession must have been sorely tried before they rose, almost unanimously, in protest against such an Act.

We are told almost daily by one section of the Press that we are employing the worst methods of Trades Unions, that we have adopted all the vices of Syndicalism, and none of the virtues, if it has any; that we have forfeited the right to the name of a generous profession. Now, however much some of us may regret the conduct of this dispute between the Government and the profession, however much small incidents may distress us and rankle in our minds, there can be no doubt that, on the main questions, the medical profession come out with clean hands. We are certainly not on strike, for what is a strike? When the coal miners struck, coal went up to such price that the poor were unable to buy it at all and the rich were forced to economise. When the taxi drivers came out, taxis could hardly be procured. But there is no evidence that any medical man has refused to treat any sick person.

What is it, then, that has united the profession as it has never been united before? Why are all medical men throughout the country breaking away from all their natural instincts, unwilling to take service under the Act? To explain this it is necessary to go into a piece of somewhat ancient history. We must examine the origin of clubs and voluntary hospitals, and so discover the reasons why the terms of the Act are so little to our taste.

It is, in a sense, our own fault that our services are regarded as of so little value. It goes back to the commencement of medical charities. All clubs had their inception in so far as the medical benefits were concerned, in the charitable work of medical men. When, about the beginning of the last century, or

earlier, the difficulty of the medical treatment of the thrifty poor was recognised, a species of insurance was started so that the cost of an illness might not cripple any one individual, being spread over many. Medical men, altruists by training, were willing to give their services to these clubs for little or nothing. It was recognised that the work was a form of charity, and it was not pretended that the fees received by the medical men were in any degree adequate reward for the services rendered, but were to prevent them from being largely out of pocket by their kindness. Many such clubs in the country have been run by my personal friends, who were out of pocket at the end of each year, but were content to continue their charitable actions, knowing how great was the value of their services to the poor.

Another form of contract practice is not uncommon in some parts of the country, especially in the colliery districts. Here the medical officer is the servant of the colliery, and the manager deducts an amount varying with the weekly wage from the pay of each collier.

Thus a roughly equitable scale is worked; a man earning £1 a week or less pays 1d., and for each £1 or fraction of £1 he pays another 1d. In this way the collier whose total earnings average £156 (£3 a week) will pay 13s. a year for his doctor. This sliding scale is in accordance with the usual medical practice to charge according to the capacity of the patient. When the large friendly societies began to cater for the same medical benefits, they were able to point to the small honoraria accepted by the medical officers of these clubs, to induce men to undertake their seemingly similar duties for the same insufficient payment.

The astute business men who were in charge of the clubs pointed out to the young practitioner how valuable was the advertisement and introduction which followed his acceptance of the club terms, and were usually able to persuade him to come to an agreement. The terms were absurdly low; some clubs even made money out of their medical attendants, that is, they levied a certain sum, say 1d. a week, from each member, and paid the medical man 3s. or 3s. 6d. a year, saving the balance for other uses of the club. If no local medical man were willing to take the work, they were often able to import an outsider who would take the post; and the mere hint of such a proposition would weigh heavily with a struggling man who would be called upon to face new opposition. It did not occur to the managers of the club—or at least they showed no signs of appreciating the fact—that the advertisement would have been just as good for the doctor if he were reasonably paid. By degrees, the status of the club altered; instead of being confined to the really poor, the limits were so widened that anyone was able, for the absurd pittance at which the club was started, to demand the services of the medical officer.

Men who joined poor became rich, but were still entitled to the medical benefits. Often, it is true, the more successful men, who belonged to the club, were willing to forego their benefits, while continuing their subscription for the good of their poorer brethren, and called in, when occasion required, a medical man at his usual fees. This might or might not be the medical officer of the club; but this was a purely voluntary sacrifice on their part, and though many did not demand sick pay in illness, feeling a natural hesitation to take from the club funds a few shillings a week which their fellows would know to be of small importance to them, a much smaller proportion refused the medical benefits; they were not unwilling to accept the benefits which could not so easily be traced.

No medical officer of such a society could make a living without a very large club, and, on the other hand, with a large contract practice, the number of patients to be seen was so great that the medical man could not give adequate attention to each. It was physically impossible to go carefully through all the differentia in making an investigation, and hence, since the work had to be done, it was very tempting to make a snapshot diagnosis, or give a *placebo*. In hospital practice, in the hurry of out-patient work, we are not exempt from this evil; but it is perhaps one

(a) Abstract of Introductory Address to the Students of St. George's Hospital, October, 1912.

of the chief functions of the student, to keep his teacher up to the mark.

There is nothing better than a surrounding crowd of enquiring students, eager to learn and perhaps not un eager to wipe, as they would say, their teacher's eye, to keep his mind alert and his diagnosis accurate.

But there is no such incentive present with the club doctor, and can we be surprised if, overworked, underpaid, without encouragement, in some cases he becomes lazy? The wonder is rather that so many do not lose all interest in their work.

By degrees this system of clubs became so prevalent that in many large towns there were hardly any inhabitants left who were not swept into the net of the insurance companies, and thus brought into the range of medical benefits. All private practices were swallowed up by the clubs.

What wonder, then, that there came an outcry from all those most interested in the welfare of the profession, that by the contract system all initiative was being destroyed and that the medical men engaged in this work were being ruined mentally and financially by it, in the name of charity? What wonder that the men who found themselves fleeced on every side were anxious to escape from it? And yet it had some advantages. The contract system did away with the necessity for a great deal of bookkeeping, always irksome to a busy man, and at the same time there was a certain income with no risk—so far as the contract extended—of bad debts. Hence many practitioners, with wife and family dependent on them, dared not, as individuals, make a stand against the clubs. And who shall blame them?

At the time when the Insurance Bill was first heard of it was recognised by all that some system of State Insurance against sickness was most desirable. Medical men were all in favour of the idea. A workable scheme, providing a service throughout the country, had indeed been suggested by some of them, and had been tried in certain localities; medical men, therefore, taking into consideration that they would have to be the chief workers under the Act, and that they had already some little experience in the treatment of the people who would come under it, remembering also that they had protested on every opportunity against the system of contract practice, not unreasonably, expected that they would be asked through their organisations, to advise on the best methods of working. However, as I shall tell you, they were not consulted; they might have thought—since they were going to bear all the risk—that the State would deal not only fairly but generously with them.

They were doomed to disappointment; the action of the Government is barely credible, and not at all creditable.

The Bill was brought in in May, 1911. In spite of repeated requests, the Chancellor of the Exchequer saw the representatives of the B.M.A. for the first time in April. This was the only deputation from the Association received before the introduction of the Bill, and at this meeting no special opportunity was afforded to the Association for ascertaining the provisions of the Bill. Nor, apparently, was the General Medical Council, nor the Royal Colleges of Physicians and Surgeons treated with more courtesy. Presumably the Chancellor had medical advisors. Who they were has not, I think, been made known; but they certainly were not the associations of medical men, who would have commanded the respect, and been in some sense at least the representatives of medicine.

When the medical provisions were known, it was at once seen that they were most unfavourable to the best interests of medicine. In the first place, the payment was to be *per caput*. This alone must stamp any scheme as liable to failure. It is not in the interest of any man's work that he should be paid at a higher rate the less work he does. It cannot induce to keenness and initiative, if the keen man is penalised because of his keenness.

The more care taken in diagnosis and investigation, the less the reward. It must not be forgotten that investigation on modern lines costs money, and this

had to come out of the funds for payment of medical men.

The Chancellor of the Exchequer has, throughout, shown himself ignorant of the first requirements of modern medicine. It is, if one may judge from his attitude, his opinion that doctors are engaged in a guessing competition, with numbered bottles which agree with the number of the disease from which the patient suffers.

Lastly, the suggested remuneration is inadequate. Of course, it is perfectly true that nowhere is it laid down in the Act what the rate of remuneration is to be; but it is acknowledged that only a certain rate is justified by the actuaries.

The Chancellor has been very generous—at our expense—to the working man in an approved society. Under the present Act the labouring man pays about 3d. a week for his medical attention. He is often willing to pay 7s. 6d. a year for the fun of keeping a dog; it is not too much to expect that he should pay as much for keeping his health.

And, again, let me mention the case of firms who own large numbers of horses. They usually pay the veterinary surgeon a contract fee to look after them, and this is usually 21s. a head. Now a horse cannot malingering, and cannot demand unnecessary medical attention.

Or, we may look at the matter another way. The Government has been hitherto willing to pay 8s. 6d. a year for the medical attention of each employee in the Post Office, who are men of picked physique and in good health. It is not likely that the Government have been paying to the medical men who have had charge of these and other public servants, twice the value of the services rendered. Why should we be asked now to undertake the treatment of all lives—healthy and unhealthy—who are compelled by the Act to insure themselves, at about half the sum which the Government has previously thought equitable for healthy lives?

In the days when I was studying medicine at Cambridge a small book appeared which was entitled, "Fables: By George Washington Æsop," in which is contained the following passage:—

"APOLOGUE OF THE KIND-HEARTED SHE-ELEPHANT.

"A kind-hearted She-Elephant, who was absent-mindedly wandering through the Jungle where the Spicy Breezes blow o'er Java's Isle, Heedlessly set Foot on a Partridge, which she crushed to Death, within a few inches of her Nest, filled by her Callow Brood. 'Poor little things,' said the warm-hearted Pachyderm, 'my carelessness has robbed them of their Natural Protector, but for the future my Solicitude shall replace the Tender Ministrations they have lost.' So saying, she sat down on the Orphan Birds."

Very similar has been the action of the Government. The lumbering elephant, dreaming, it may be, of the rare and refreshing fruit in the distance, by its clumsy act has destroyed the value of the doctor's practice and robbed him of his freedom; and when this was pointed out, declared that it would make up all his losses by allotting the sum of 6s. a head, out of which, first, the drugs and surgical appliances were to be paid for, and the balance, if there were any, was to be given for the doctor's services.

Surely, on all counts we are fully justified in our rejection of the scheme designed by the Government and in our determination to build up a better public medical service by our own efforts.

NOTES ON OTHER INTRODUCTORY ADDRESSES AT THE OPENING OF THE MEDICAL SCHOOLS.

The following are brief abstracts of some of the introductory addresses delivered last week at the opening of the winter session of the medical schools:—

UNIVERSITIES AND MEDICAL TRAINING.

Speaking at the Victoria University of Manchester, Dr. H. D. Rolleston, Senior Physician, St.

'George's Hospital, said that the ideal standard was that every student of medicine at his entrance to the profession should be a graduate in arts, with a sufficient knowledge of physics, chemistry and biology, and of French and German; but these requirements demand more time than can or should be afforded by the average student, and it is for the average student that arrangements and regulations must be adapted. Those who advocated that the preliminary subjects should be taught in the schools usually include biology with chemistry and physics, and this plan was obviously advantageous from the point of view of saving time. But the specialised biology necessary for medicine required the services of a medically-minded teacher in a greater degree than do chemistry and physics, and would therefore appear to be more conveniently carried out in university laboratories than in schools.

In view of the extensive demands on the medical student it had been suggested that the time spent on anatomy and physiology should be curtailed by altering the teaching so as to insist on those details only which are of obvious practical use in medicine and surgery. Thus medical and surgical or applied anatomy, and not the science of anatomy, would be taught, and the minute details of bone markings, the relations of muscles, and other points in descriptive anatomy which have no direct utilitarian bearing would be omitted. Physiology would be pruned to some extent—for example, by the elimination of exercises in muscle-nerve preparations. On the other hand, more attention would be paid to visceral topography and to the minute study of fresh organs.

Apart from their direct practical application, these sciences had a great educational value. Practical anatomy educated the powers of accurate observation and of classification, trained the memory, developed the inductive processes of reasoning, and conferred manual dexterity and quickness of eye. In English universities the professorships of medicine and surgery differed from those of other faculties. Their incumbents, unless possessed of ample means, were mainly dependent for their living on sources outside the university, and therefore engaged in private practice, which must often form the chief interest of their life; whereas the professors of other faculties received a living wage on the tacit understanding that their activities should be entirely devoted to their chairs.

The duties and responsibilities of a clinical professor included (1) the care of the sick in the hospital; (2) clinical instruction in the wards, clinical and, perhaps, systematic lectures; (3) official duties in the university and medical school; (4) the cares and anxieties of a consulting practice rendered necessary to earn a living and to provide for his family and old age; (5) reading and investigation of new methods so as to keep abreast of modern knowledge; and (6) original research in order to advance the science of medicine. The claims of the first four of these spheres of activity left little time for anything else, and especially rendered research almost impossible. It therefore followed that one of the functions of a university—namely, original research for the advancement of scientific medicine—was practically prevented by the conditions under which the professors hold office.

BACTERIA AND RADIUM.

At the Middlesex Hospital, Dr. W. S. Lazarus Barlow, in an address upon "The Genius of the Infinitely Little," referred to the minuteness of the agencies at work in some of the most important

functions of life. He instanced the production of an infectious disease, its non-production, and the exaltation of virulence in bacteria as examples.

After explaining the extreme minuteness of the rays shot off by radium, Dr. Barlow claimed that it was not difficult to anticipate, what was indeed the fact, that cancer cells and bacteria could be destroyed by them. Even the tubercle bacillus and the anthrax spore, highly resistant though they were to germicides, were killed by the alpha and the beta rays. It could well be imagined that in the not very far distant future radium would be utilised not only to combat cancer (in whose case they had already some knowledge of its efficacy at times), but would also be used in the treatment of bacterial diseases. There was, he added, evidence to believe that smaller doses of radium radiation were stimulative. There were already indications that the idea was not absurd, and, if so, the question presented itself for solution—What was the meaning of the minute quantities of radium found within the human body? But these were speculative regions. Dr. Barlow then drew attention to a few of the fundamental facts about the group of the so-called enzymes, and concluded his study by a reference to the germ cells and a support of the contention that the most marvellous of the marvels they were called upon to consider as biologists was, in spite of Professor Schäfer and the philosophers at Dundee, that all the mysterious complex of physical and intellectual activity which went to make up the individual had been produced by the genius of a cell, not infinitely little, perhaps, when compared with a beta particle of radium, but still less than a hundredth of an inch in diameter. In conclusion, he welcomed the new students to the hospital. He urged them to remember that the reputation for honour and beneficence accorded to the profession by the public was won for them by the genius of the infinitely little ones of medicine in the past; those whose race was more than half run were striving day by day, and after their infinitely little fashion, to hand on to them the torch of honour undimmed.

COMMON SENSE.

At the London (Royal Free Hospital) School of Medicine for Women, Miss Jane Walker, in the course of her address, said that common sense was a faculty to which everyone believed they could lay claim, though, as a matter of fact, it was a very rare possession, and one excessively difficult to define.

Although their own rôle in life was the prevention and cure of disease, they made only the most piecemeal attempts to prevent disease. They allowed people to wait till they were really ill, and in many cases past recovery, before they attempted to deal with them. They made the patient diagnose his own condition of illness and come to them, instead of their going to him and hauling out cases in which illness was beginning into the arena to be forewarned or treated if necessary. A really poor middle-aged single woman, to whom the loss of a day's work meant something very considerable, would hold on till she could do so no longer, and then she went to the out-patient department of some hospital, humane enough to admit her without the subscriber's letter, and waited for hours in a stuffy, ill-ventilated hall, with dirty vicious people, afflicted, it might be, with infectious diseases of various kinds, until her turn came to be seen only, in so many heart-breaking instances, to be told "it is too late to do more than patch you up," or "the disease is beyond the power of relief, even by means of operation." The authorities of

the King's Fund ought to make a bonfire, on his Majesty's birthday, of hospital letters. Such letters assumed the vanity of the small subscriber and played up to it, they worried and alienated the poor, and they were a survival of the bad Georgian way of patronising the unfortunate.

In regard to the work of medical students, one heard a great deal about all work and no play making Jack a dull boy; but it did not make either Jack or Jill dull at their studies. Possibly it might not verse them in topics which would add to the gaiety of a dinner party, but to do so was not their business. The author of *Confessio Medici* had recorded the speech of a patient to a friend of his: "I don't want my doctor to talk to me about the National Gallery." That was a shrewd saying. Patients wanted their doctor to have had some one else with just their complaint, only worse, but who had nevertheless got well; and cared far more about that than that their doctor should be an artist of no mean standing, or an enthusiastic student of Browning. The majority of their patients would be poor people, and common sense would be of assistance in dealing with them. It would lead them, for instance, to avoid saying to a dirty, lousy, old woman from Whitechapel, "Do you take a daily sponge bath, Ma'am?" as the speaker had once heard a young house-surgeon say. It would prevent them, too, prescribing champagne and oysters for a private patient whose income was under 30s. per week. The patient might try to get them and succeed, but they would not do her much good, and one result would be a request that the medical attendant's account should be allowed to stand over indefinitely. Dr. Jane Walker concluded by quoting the following lines from Pope: Something there is more needful than expense, And something previous e'en to taste—'tis sense, Good sense which only is the gift of Heaven, And, though no science, fairly worth the seven.

MEDICAL MEN AND MUNICIPAL AFFAIRS.

Having distributed the awards to the successful students at St. Mary's Hospital, the Lord Mayor of London, Sir. Thomas B. Crosby, M.D., said that he hoped when the report of the Commission now inquiring into the affairs of the University of London was issued, some words would be found securing for those who took the joint degree a real degree, instead of their merely being allowed to place a few letters after their name. London degrees were admirable, of course, but colleges which had existed ages before the University of London should have the power of conferring higher degrees upon those who passed their examinations than they possessed at the present time. He had always thought that the medical profession in days gone by had neglected golden opportunities by its members avoiding attaching themselves to such questions as local government. He urged upon the students the importance of taking their share in the work of rural or corporate bodies. They would become leaders, because they knew what was wanted for the health of the people. Such questions were a part of their education, and they would know far better than engineers and that sort of people, the needs and requirements of a community. "I will not allude to a political question," said the Lord Mayor, in conclusion, "but I find it difficult work indeed to keep out all reference to it. When I became Lord Mayor I put my politics under the table, and luckily I have not since then bent down to pick them up. But I have received many earnest applications from brother professional men, who thought, with justice I think—though that must be regarded *sotto voce*—that they were not having

fair treatment at the hands of the Government. They, however, have taken the matter in their own hands, and I think they will succeed."

OPERATING THEATRES.

UNIVERSITY COLLEGE HOSPITAL.

TRIGEMINAL NEURALGIA.—REMOVAL OF GASSERIAN GANGLION IN A WOMAN, ÆT. 83.—MR. MORRISTON DAVIES operated on a woman, æt. 83, who had been suffering many years from severe right-sided trigeminal neuralgia, for which she had been treated by different methods with only temporary improvement. The previous operative treatment had consisted of peripheral neurotomies and alcoholic injections. The extreme danger of removing the Gasserian ganglion in a person of her age was explained to the patient, but she expressed herself as quite willing to run all risks rather than continue to suffer the constant excruciating pain or to submit to further local treatment. Owing to the advanced age of the patient, Mr. Davies decided to do the operation in two stages, so as to diminish as far as possible the shock. The first stage consisted in turning down an osteoplastic flap from the right side of the skull in the usual position for reaching the ganglion by the Hartley-Krause method. However, in this case the size of the bone flap was larger than usual. The dura mater was found to be very adherent to the cranium, and was stripped up from the floor of the skull for a distance of about an inch with considerable difficulty. The flap was then replaced and stitched in position.

The patient recovered from this part of the operation without much shock. Ten days later the second stage of the operation was undertaken. The flap was turned down once more, and the stripping of the dura and the raising of the brain from the floor of the skull were continued until the middle meningeal artery was exposed. Two ligatures were placed round the artery, which was then divided between them. The raising up of the dura and brain was now continued until first the inferior maxillary division and then the superior maxillary division could be seen passing out through their respective foramina in the base of the skull. The dura covering the Gasserian ganglion was divided, and the ganglion then freed from its adhesions to the surrounding tissues on its upper and lower surfaces. No attempt was made to define the inner border of the ganglion or the ophthalmic division, as it was intended to leave these so as to minimise the risks and shorten the length of the operation, and no pain had ever been experienced in the area supplied by the ophthalmic division. The inferior and superior maxillary divisions were divided at their point of exit from the skull, and the ganglion itself was divided between the ophthalmic and the superior maxillary divisions so as to leave, however, the whole of the sensory root attached to the main part of the ganglion. The ganglion was now free except for its attachment to the brain by its sensory root. The ganglion was seized in a pair of forceps and the sensory root plucked out from the brain, and a gauze plug immediately pushed down to the cavum Meckelii so as to prevent blood trickling back on to the base of the brain. The brain was now allowed to return to position, and the osteoplastic flap adjusted and stitched in position, the plug being brought out posteriorly through one of the trephine holes.

Mr. Davies said that there were certain special points about this operation to which he wished to draw attention. The removal of the Gasserian ganglion in a moderately healthy young or middle-aged person, he remarked, does not present any special difficulties, but in old people and in patients with markedly sclerosed arteries the operation is one of considerable danger, and it was for this reason that he had made certain modifications in the ordinary procedures of a Hartley-Krause operation. In the first place the operation was done in two stages instead of one to minimise shock as far as possible. In the second place the opening in the skull was con-

siderably larger than usual, so as to prevent too great compression of the brain when raising it from the floor of the skull, by allowing, to a certain extent, of a bulging outwards of the brain through the opening. Thirdly, it is of the utmost importance that the pressure of the retractors on the brain should be as little as possible and of as short a duration as possible. The best way of ensuring this, in my thought, was that the surgeon should hold the retractor in his left hand while freeing the dura and adhesions, and the retractor need only be given to the assistant during those periods when the operator requires both his hands for some particular manipulation, such as the ligation of the middle meningeal artery. Fourthly, the middle meningeal artery was ligatured before it was cut. This, he considers, should be a routine procedure, as the hæmorrhage from the divided artery is often extremely troublesome. Lastly, no attempt was made to remove the ophthalmic division, as it is unnecessary to do this when there has been no clinical evidence of its involvement. This shortens the time occupied by the operation to a slight extent and minimises the risk of injury to the sixth nerve.

The anæsthetic used in this case, Mr. Davies pointed out, was chloroform, and it is important to remember, he said, that once the skull is opened the amount of the anæsthetic given must always be diminished.

The patient made an excellent recovery, and had, of course, lost all pain; she showed no symptoms whatever of cerebral softening or of neuropathic keratitis. When last heard of 18 months after operation she was still quite free from pain.

TRANSACTIONS OF SOCIETIES.

MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.

MEETING HELD OCTOBER 4TH, 1912.

The President, DR. FREELAND FERGUS, in the Chair.

DR. ROBERT KENNEDY demonstrated an interesting series of

CASES AFTER OPERATION FOR VARIOUS FORMS OF PARALYSIS.

(a) Case of a man, æt. 30, which illustrated a peripheral nerve lesion, and therefore was associated with atrophy and degeneration of the muscles, and which, after operation, is a considerable time before recovery takes place on account of the atrophy. The man tripped and fell on December 9th, 1911, and sustained a dislocation of the left shoulder. The dislocation was reduced two days afterwards and the arm put in a sling. It was kept up for about a month, and, at the end of that time when the patient tried to use it, he found he could not do so as the arm was paralysed. He was sent to Dr. Kennedy on March 4th, 1912, three months after the dislocation and admitted to the Glasgow Royal Infirmary. At that time the following condition was found on examination: he could raise the left arm at the shoulder barely to a right angle, but in doing this the scapula was pulled forwards, which action is due not to the deltoid but to the trapezius and the lower part of the serratus magnus pulling on the scapula. He could partly flex the arm, but it was very weak, showing a certain amount of power in the biceps. Supination was very weak and defective, being scarcely present at all; no power of extension, and complete wrist drop. He was able to extend the fingers only at the second distal joints, not at the proximal joints, which is caused by the muscles of the hand. There was no power in the extensors of the forearm and there was loss of complete flexion. With regard to sensation, touch sense was present everywhere but dull, and the sense of pain was present.

The lesion was evidently not a complete rupture of the brachial plexus, but only partial.

On March 4th, four months after the injury, the

brachial plexus was exposed, when the trunks of the plexus were found to be compressed by cicatrices. The plexus was dissected out of the adhesions, which proved a very difficult procedure. The scar of the incision was in the axilla. The wound healed by first intention.

Three months after the operation, that is in July, the patient began to recover movements of the arm, and four months afterwards—*i.e.*, August 6th, sensation was found to be normal.

The present condition of the patient is that he is able to abduct his arm against considerable resistance to an angle of about 135 degs., to flex the elbow with very considerably increased power, and supination is almost normal. Extension of the wrist is completely restored. The electrical reactions before and after operation are interesting. The faradic current to the deltoid before operation had no response at all, but now gives a minimum response at the separation of the primary and secondary coil at 60 mm., compared with 80 mm. at the sound arm. The biceps before operation gave a response in the injured arm at 52 mm., compared with 90 mm. in the sound arm, but after operation now gives response at 80 mm. The extensors of the forearm over their nerve supply and muscles gave no response before operation, now respond at 60 mm., compared with 65 mm. in the sound arm. The galvanic current shows much the same kind of affairs.

The measurements of the arm taken eight inches from the acromion process show in circumference the left arm to have been $9\frac{1}{2}$ inches, before operation the sound arm, $11\frac{1}{4}$ inches, showing a deficiency of $1\frac{3}{4}$ inches in muscular substance. On October 2nd, 1912, the injured arm measured $10\frac{3}{4}$ inches, thus showing $1\frac{1}{4}$ inches of muscular substance to have been regained, and only $\frac{1}{2}$ inch to make up the same size as the healthy arm. The same thing was noticeable in the forearm; the measurement taken $1\frac{1}{4}$ inches below the flexor, where before operation the measurement was $9\frac{3}{4}$ inches, compared with 11 inches on the sound, now measured $10\frac{3}{8}$ inches, showing an increase of $\frac{3}{8}$ inch in six months.

(b) A case of birth paralysis or Duchenne's paralysis.—Where the lesion is found in the brachial plexus at the junction of the fifth and sixth nerves and sometimes also the seventh. It is either torn or compressed by cicatrices. The child was operated on in August, 1908, being at the time two months old, which is the best time to operate, provided there are no faradic disturbances in the muscles. The lesion was produced at birth and the arm was completely paralysed. The child could not abduct the arm because of the deltoid, could not flex the arm because of the biceps, being useless, could not supinate and could not volate the arm outwards. At the operation the lesion was found to be a cicatrization band encircling the junction of the fifth and sixth trunks, and on cutting the band it sprang apart leaving a furrow in the nerve trunk. Healing was by first intention. On December 14th, 1908, abduction of the arm to 120 degs. and flexion to 90 degs. Supination was still absent, but this is always late in returning. The child was now shown four years after operation with a very satisfactory and useful arm. There is still a very slight weakness of the supinators, and this may be explained by the difficulty that is experienced of getting the mothers to give passive movements in hospital patients.

(c) A case of complete paralysis of the arm resulting from a cortical lesion, in a man, æt. 32. On November 19th, 1911, a heavy door fell and struck the left side of the head, inflicting a wound to the scalp and fracture of the vault. He lost consciousness for three days, and when he came to himself it was found that he had paralysis of the right side and had lost the power of speech. Five days after the accident he was taken to hospital, and speech returned in ten days, and a week later movements of the right foot. Three weeks after this epileptiform seizures occurred, accompanied by buzzing in the head, tremors in arm and twitching of the face. No other improvement occurred after the accident.

The left side of the scalp showed a large and deep cicatrix, the upper end commencing six inches from the glabella and extending downwards three inches above the ear. Above this defect of the skull a piece of bone projected. Pressure produced tremors of the right hand, and on one occasion pressure brought on a typical epileptic attack, the right arm, leg and face being involved. Complete loss of consciousness, dilated pupils, and head thrown back. He remained unconscious a quarter of an hour.

The lesion was situated over the pre-central gyrus and the upper part of it, involving the shoulder, elbow, fingers, wrist and thumb. He was operated on in June, 1912, seven months after the accident. The operation consisted of removing the scar from the cicatrix and some spicules of bone from the cortex. The cortex was damaged by the scar, and on attempting to stimulate the brain by electrical methods no response was obtained, because it loses its excitability very rapidly.

The day after the operation—viz., June 21, 1912—he lost the tremors of the arm and made voluntary movements, and the fingers could be brought into contact with each other. Abduction and adduction, supination and pronation could be accomplished. He could also raise his arm at the shoulder and grasp the rail at the head of his bed within twenty-four hours of operation. Some tremors are still present, but he is able to perform all voluntary movements.

(d) Lesion in the spinal cord affects the anterior horn, causing obstruction to the nutrition of the muscles, and is a case of infantile paralysis. The operation here consists in what is known as tendon grafting, and consists in taking muscles in the neighbourhood and making them do the work of the paralysed muscles. For instance, if the extensors are the muscles affected, then you split the flexor, and make one-half of the flexor do the ordinary work of the extensor. A child, *æt.* 7, had talipes equinus of the right foot and infantile paralysis six years ago. She walked on her toes, had no power of extension, and the foot was everted. The gastrocnemii were bulky. The electric examination gave normal response to the gastrocnemii, but it was absent in the anterior group of muscles.

On May 24th, 1912, an incision five inches long was made on the outer side of the gastrocnemii and the muscle split into two parts, one-third of the muscle being used as a flexor, the remaining two-thirds for extension. The muscle was lengthened, not cut. An incision over the paralysed tendon and a tunnel made at the lower end of the wound, a probe threaded, enabled the part of the muscle to act as flexor. The child now walks on the sole of her foot. That the gastrocnemii have voluntary power of producing flexion of the ankle can be proved by electric stimulation, and in addition the thickening of the split muscle is visible in the child's leg during contracture.

Drs. Renton, Hunter, Findlay, Young and Edington took part in the discussion which followed.

Dr. W. K. HUNTER described and showed X-RAY PHOTOGRAPHS FROM A CASE OF SCLERODERMIA, WITH CALCAREOUS DEPOSITS IN THE SUBCUTANEOUS TISSUES OF THE FINGERS.

The case was that of a woman, *æt.* 39, admitted over a year ago, who had been under observation and treatment for three months. Her illness began when 14 years of age with the phenomena of Raynaud's disease. At 18 years of age she had pains in her joints, involving all the joints of the upper and lower limbs except the shoulder and hip, and this continued more or less to the age of 25 years. About the time of the pain in her joints she began to feel the skin of her hands begin to get very tight. Her hands did not grow in proportion to growth elsewhere, and changes in her face became noticeable. Photographs of the patient aged 15, 18, and 25 years show that there was no affection of the face at 15 years of age, but it shows itself afterwards.

At 21 years of age, when the disease had gone on for seven years, she began to have little nodules round about the finger joints, and after a time the skin over them gave way and exposed little chocolate-coloured substances, which came away. Sometimes

suppuration occurred before these substances became detached, and sometimes afterwards. Skiagrams show infiltration of the soft parts. The feet became affected with deposits, but never much sclerodermia.

The face has got a thin, pinched appearance and the mouth is small, and there is difficulty in opening the mouth fully. She has thin, pointed fingers. The limits of sclerodermia are not well marked, and the affected skin passes into the unaffected skin. The abdomen and front of chest are not affected. There is a good deal of limitation of movement, and she is unable to get her arms quite straight, and has difficulty in going upstairs due to the tightness of skin in the gluteal region, and also difficulty in getting up after sitting or lying down. The treatment has been by injection of fibrolysis for 8-9 weeks, and she says it does her good and she is more supple. The calcareous deposits in the subcutaneous tissues are exceedingly rare, and Dr. Hunter had been able to find only two other recorded cases, both reported within the last twelve months.

The relationship of Raynaud's disease to sclerodermia is very fine and very close. Regarding the pathogenesis, not much is definitely known, the most obvious explanation being that there is a sclerosis of tissue which encourages the deposit of calcium salts.

Dr. HUNTER also showed blood films from a case of infantile splenic anæmia (aplastic anæmia?).

Dr. G. H. EDINGTON read an account of two

UNUSUAL FORMS OF SPINA BIFIDA.

(a) Female patient, aged four months, and sent to hospital on account of swelling at the back of the neck. At birth the child was quite fat, and a swelling at the back of the neck was thought to be a relay of fat, but the swelling increased out of proportion to the general growth, and the child was sent to hospital. The appearance of the parts showed that the whole breadth and length of the neck was occupied by the swelling. The skin over the swelling was of normal thickness, but slightly oedematous, with no excess of hair, no translucency, and when the child cried there was no difference in the size of the swelling, nor was there any disturbance of the nervous system on compression. On palpation of deeper parts there was a structure resembling a piece of cartilage or bone, which was not connected with the spinal column and quite easily moved about. A skiagram showed two shadows, one far out and the other attached to the vertebræ. The arch of the second vertebra was absent. The tumour was presumed to be a meningocele, with no connection with the spinal column, or very small connection, and operation was carried out. On cutting into the mass nothing was found beyond fat, and only when deep down was found a spina bifida without meningeal protrusion, the great bulk of the mass being fat. Recovery was uneventful.

With regard to the presence of a mass of fat as differing from ordinary lipoma, there was no circumscription of the swelling and no lobulations, but on the other hand, unlike the lipoma accompanied by spina bifida, there was no excessive growth of hair, which is quite frequently seen and written about. The bony structures were partly cartilaginous and partly bone, and were undeveloped lamina.

(b) Female, aged 4 months, had a large cystic mass projecting from the back of the right hip, not in ordinary position of spina bifida, but springing from the outer surface of right innominate bone; the lower limit was in a fixed position of extension and markedly everted. The swelling was congenital and had increased considerably in size. The swelling was punctured and eighteen-and-a-half ounces of fluid evacuated. The patient was brought back again in three days with the swelling as large as ever and more radical measures were decided upon, and it was cut down upon. It was found to be covered by muscles. After clearing the sac it was again punctured and a like amount of fluid removed. The sac was then slit open and on the ventral surface nearest the back a substance like cord and a small hole with many cords.

The child collapsed and died within twenty-four

hours. At the *post-mortem* examination the chief interest was the condition of the spinal column. The laminae of the left side were well developed, but tended to point straight backwards, but the posterior ends were nearest the centre. The laminae of the fourth and fifth lumbar vertebrae were rudimentary and a large opening was looking out from the spinal column towards the right hip. The violation of the sacrum on the long axis and towards the right caused a certain degree of scio. The sacrum was dislocated upwards and lay behind the fifth lumbar vertebra.

FRANCE.

Paris, Oct. 5th, 1912.

TREATMENT OF FEVER.

THE treatment of fever due to infection or microbial intoxication, the only one referred to here, should be essentially pathogenic and symptomatic when it is not specific.

The treatment of infectious disease, says Dr. Luc Vital, rests on four fundamental principles:—

- (a) Annul the action of the pathogenic microbes.
- (b) Annul the action of their toxins.
- (c) Lower the high temperature.
- (d) Enable the organism to resist the infection.

To act directly on the microbes, internal antiseptics was tried, but beyond quinine in paludism, mercury in syphilis, salicylic acid in rheumatism, that method gave little results.

To annul the action of the toxins, the only aid to their elimination may be found in purgatives, diaphoretics, diuretics, hence, exception being made of the above specific injections, the therapeutics of fever are purely pathogenic and symptomatic.

The principal symptoms of fever are: Thirst, oliguria, hyperthermia, acceleration of the pulse, adynamia.

For the thirst the patient should be given abundant drinks, not only to relieve the inordinate thirst, but as the best means to provoke diuresis and diaphoresis, necessary to the elimination of the toxins.

A patient suffering from infectious disease should consequently drink largely. Lemon water (two lemons cut up for a quart of boiling water), apple tea, etc., are agreeable drinks. Citric lemonade is particularly indicated in acute rheumatism:—

Citric acid syrup, 3 oz.

Water, 1 quart.

In affections of the intestine lactic acid might be prescribed:—

Lactic acid, 2 dr.

Syrup, 3 oz.

Water, 1 quart.

For oliguria lactose might be given to increase the diuresis; two ounces in a bottle of Evian water.

To aid in the elimination of the toxins, purgatives should be given, castor oil, or sulphate of soda:—

Sulphate of soda, 1 oz.

Lemon syrup, 1 oz.

Water, 9 oz.

Calomel is useful both as a purgative and a diuretic, two grains every hour for four hours.

Enemas of cold water also favour diuresis (8 oz.).

Hyperthermia.—There is no special treatment for hyperthermia as long as the temperature does not exceed 102° F.

One of the most active means of acting against it is cold water; cold baths (77 deg., ten to fifteen minutes), lower the temperature by one degree. Their further effects are: increase of the diuresis, elimination of the toxins, and stimulation of the organism. Cold compresses on the abdomen should be prescribed in the interval of the baths, while a stimulating mixture should be given before and after the bath:—

Tincture of cinnamon, 1 dr.

Syrup, 1 oz.

Brandy, 1 oz.

Water, 3 oz.

Where cold bathing is refused or not possible, cold effusions may be practised every two hours; spirit of lavender may be added to the water.

Antithermic drugs are of little use; however, phenacetine might be given:—

Phenacetine, 6 gr.

Citrate of caffeine, 2 gr.

for one wafer; one to two a day.

Tachycardia.—The pulse should always be the object of careful attention as it furnishes important indications on the state of the heart and the degree of resistance of the patient. Where the pulse is small, depressible, and exceeds 120, a cardiac tonic is required: small and repeated doses of sulphate of sparteine ($\frac{1}{2}$ gr. three times a day) fulfil the indications.

Adynamia.—The strength of the patient should be kept up as much as possible, but only by liquid food: milk, vegetable soups, decoction of cereals, lemonade mixed with a little wine, weak coffee. Hypodermic injections of camphorated oil repeated frequently or injections of strychnine form the medical treatment.

GERMANY.

Berlin, Oct. 5th, 1912.

THE Sixth International Congress f. Geburtshilfe und Gynäkologie continued the discussion on the

TREATMENT OF WOUNDS OF THE PERITONEUM.

Hr. P. Lecène, Paris, said that the great advances that had been made during the past ten years were to be traced to certain factors: methodical employment of indiarubber gloves, strict asepsis, accurate peritonisation of bleeding surfaces either with or without the shutting off of the small pelvis, more accurate determination of the indications and a better system of drainage.

Hr. Resinelli, Florence, said the best result, both in septic and non-septic cases was obtained by the complete removal of blood and other fluids from the abdomen, complete union of all solutions of continuity in the peritoneum, careful avoidance of all injury, or immediate repair if any had taken place to intestine, bladder or ureters. Drainage in the free abdomen was only exceptionally to be made use of. Flushing out of the abdominal cavity with physiological solution was of doubtful value. Preventive injection of oil of camphor into the abdominal cavity was not an advance in treatment. The results of his own experience in cancer of the cervix uteri justified the speaker in recommending hypodermolysis with a solution of nucleic acid as an active agent. It was indisputable that the great necessity for the most accurate asepsis remained for laparotomy, but the result depended mainly on precision and advances in technique.

Hr. B. J. Kouwer, Utrecht, said that the result in clean cases of laparotomy depended equally on technique and asepsis. Cell tissue was more readily infected than the peritoneum. Mechanical irritation of the abdominal wound was to be avoided; this was of great importance. In regard to this the use of the usual abdominal speculum, especially where the incision was but small, was of importance.

Hr. Josef Lovrich, Budapest, said they provided for a complete evacuation from the bowels; they had never seen any harm from it. Remarkably often one found hidden cysts filled with many micro-organisms. A pyelitis, even, of medium degree might be present without any very marked symptoms. Weaker patients, the day before operation, got, in addition to good feeding, moderate doses of digalton, and rest was insured the night before the operation by veronal. They only operated at the time of menstrual congestion when it was unavoidable. On the day of the operation the patient, early in the morning, got 0.5 gm. of veronal. The bladder was washed out and the vagina disinfected immediately before the commencement of the operation. As preparation of the field of operation they made use of soap, warm water, acetic alcohol, and 5 per cent. tincture of iodine. The operator who had begun the operation must close the abdomen.

The abdominal opening was always made sufficiently large to allow of easy manipulation. They never used a very high Trendelenberg position. The

blood-vessels were ligatured separately as much as possible. Every wound of the abdominal cavity was covered with peritoneum. If at any operation they were not quite certain of absolute asepsis, Douglas' pouch was drained with iodoform gauze; the drainage could be carried either upwards or downwards, whichever way seemed the more practicable.

In the Wertheim operations the parametrium of both sides was drained with small strips of iodoform gauze, and besides this the abdominal cavity was also drained with similar strips, which were carried down below through small openings in the vaginal arch.

They laid great stress on setting up peristaltic action in the bowel within the first twenty-four hours. "Peristaltic Hormon" was an excellent remedy, but wine-glycerine enemata had served them the best.

Patients recently operated on could move themselves in the bed freely; foot and arm movements, lung-gymnastics, oxygen, digalon according to requirements completed the treatment. As regarded early getting up, laparotomy patients rarely wished to get up for the first few days, and there was no reason why they should do so. Patients got up generally from the 8th to the 10th day; after the sutures had been removed. They got up of themselves.

At the Budapest Womens' Klinik from March 1, 1903 to January 1, 1912, 960 celiotomies had been performed of which 101 were through the vagina with a mortality of 5.9 per cent. Through the abdominal walls 859, with a mortality of 8.6 per cent.

Herr A. V. Mars, Lemberg, said that after improved technique and complete asepsis a considerable improvement had taken place in operations of all kinds. The cause of death was but rarely general septic infection; it was almost always peritonitis. An improvement on these results should be striven for by raising the resisting power of the peritoneum and diminishing the sensitiveness to infection. The method of procuring asepsis also should be simplified.

Herr Wertheim, Vienna, said the utmost possible avoidance of damage to the peritoneum (mechanical, chemical or thermic). Working in the cleanest and driest manner, and especially removal of all necrosed tissues covering all injured parts of peritoneum. Proper treatment of the sub-peritoneal spaces, avoidance of any retentions by keeping an opening if possible through the vagina. Shutting off of the intra-peritoneal regions in case they were infected, or there was suspicion that they might become so. Where parts could not be covered with peritoneum they should be shut off by means of gauze, or they might be kept open.

AUSTRIA.

Vienna, Oct. 5th, 1912.

RENTEN-NEUROSIS.

RUDINGER complains of the absence of laws to guide the nerve specialist in writing a certificate for the Compensation Act. Neurosis after an injury is not a self-created prodroma, but a sequence of the injury and ought to be considered in the compensation. The loss of time for the repair of the injury is provided for, but where the repair of nerve system is prolonged indefinitely the specialist is at a disadvantage to determine the period of recovery. Again, there are cases where the objective symptoms frequently improve while the subjective remain stubborn and refractory.

The former when conducted in a suitable institution can be measured and estimated with some feeling of accuracy but the latter is left to guesswork. Some patients are less sensitive and may after a time of rest recover rapidly where another class may have the impression more deeply fixed on the nerve centres, so that it becomes impossible to determine the period the patient may be unable to work and the loss sustained in wages during that time.

OXYPROTEINS AND AMINO-SALTS IN URINE.

Erben's method of estimating the oxyprotein alloxyprotein and antoxyprotein with mercurial acetate in an acetic solution is not quite free from objection as the fractional parts are not measured, and disagree with Falls', Salomon and Saxl's results which

are also too high. Ginsburg's method with the oxyprotein and amino salts as well as the glycolcol are no higher. Again, the value of the nitrogen in the oxyprotein salt in an alkaline solution does not exactly measure the protein salt as the precipitate varies. Erben finds that the mercurial precipitate of oxyprotein acid, antoxyprotein, and alloxyprotein is distinctly increased in phosphorus and lysol poisoning as well as in diseases of the liver and diabetes mellitus. In these diseases the value of the oxyprotein nitrogen averages 0.3 and 0.5 of a gramme eliminated daily, which is from 2.3 higher than the whole amount of nitrogen present. This is a value given by Falks, Salomon and Saxl as a diagnostic symptom for carcinoma. The oxyprotein salt is largely increased in infectious diseases, pernicious anæmia and leucæmia. In the first it is found in the crisis and passes off in the lysis. In typhus it is 0.36 grammes or 2 per cent., in pneumonia it is 0.31 gramme or 2 per cent., and in leucæmia or after treatment with Roentgen rays it is as high as 0.36 gramme, or 2.2. per cent., but in chlorosis and nephritis it is normal, in the latter it is decidedly less. These results show that an auto-phagistic process is active even when no disease is present in the liver, which increases the elimination of the oxyproteinic salt. The increase of this product in stenosis of the bowel and pylorus when of a benign nature is the result of inanition as it is a consumption of the proper material of the body. While carcinoma is of a genuine auto-phagistic process as well as diabetes mellitus and fever.

The elimination of the amino salts does not run parallel with the oxyprotein as they are slightly higher in hepatic disease and phosphorus poisoning, as in the latter *sub finem vite* it rises to the enormous height of 1.2 gramme while the glycol registers 6.5 grammes eliminated in one day, or 6.7 per cent. of a total nitrogen. In diabetes mellitus the amino salt is proportional to the elimination of the total nitrogen ranging to about 0.3 gramme of nitrogen equal to 1.6 gramme of glycolcol. In pernicious anæmia the elimination of the amino salt is increased, probably due to implication of the liver, while the same may be inferred of infectious diseases of the crisis and lysis. There is a striking reduction in the elimination of this salt in measles, typhus and pneumonia and also in diabetes and nephritis approaching death.

HUNGARY.

Budapest, Oct. 5th, 1912.

At the last meeting of the Budapest Medical Society Dr. Kiss read a paper on

DISORDERS OF THE HEART IN JUVENILES.

He has found comparative hypertrophy of the artery walls not an uncommon discovery in older children and at puberty, but the blood-pressure with it is not materially increased, although there may be palpitations and a sense of oppression in the chest. The cause is a "growth hypertrophy," as a rule, although excessive masturbation may induce a similar syndrome. The lack of dilatation of the heart, of murmurs, the normal size of the liver, the good health otherwise and absence of aggravation of the symptoms by physical exercise render an organic lesion improbable. Children are particularly prone to arrhythmia on the slightest excuse, and the harmless arrhythmia is distinguished by the full and powerful pulse-beat: the diastole alone varies in length. This form of arrhythmia also subsides if the heart action becomes accelerated, as then the abnormally long diastoles are shortened. This infantile type of harmless arrhythmia may persist beyond puberty, and give grounds for alarm if casually discovered first in a young, pregnant woman. Arrhythmia due to actual organic disease is generally the result of extra-systoles. Extra-systoles may be accepted as suspicious of a genuine organic heart lesion; at the same time, they may occur solely from some nervous affection, and may even be the first manifestation of an organic nervous disease. No one to date has succeeded, he says, in inducing extra-systoles by irritation of the heart nerves. The arrhythmia in tuberculous meningitis is of the infantile type, that is it seems to be due exclusively to diastoles of varying length. Heart murmurs may

also be observed without organic lesions, he adds; Lüthje found systolic murmurs in 623 out of 857 children examined, but only 2 per cent. of the total number had certain signs of valvular disease. Beyer detected a systolic murmur in 352 of 830 school-children examined, most frequently in girls. In 253 cases the murmur was audible during repose; in the others, only after gymnastic exercises. The murmurs did not parallel findings of anæmia, and in only 14 cases were concomitant signs of a heart defect to be detected. Kiss explains these accidental murmurs as due merely to certain physiologic and anatomic peculiarities of the circulation in children, differing possibly in the various cases, such as a more rapid flow of blood in the anæmic, or a slight, transient, muscular, mitral insufficiency.

DIET IN DIABETES MELLITUS.

Dr. Menyhért declares that the diet should be individualised for the patient, and the special phase of the disease more than is generally done. It has been his experience that the way in which the carbohydrates are prepared for the table is of the greatest importance for their tolerance by the diabetic. They are tolerated best in the form which takes the longest time for their absorption, and which passes most slowly into the blood, such as coarse, tough, moist bread, rather than fine, dry and toasted bread; baked potatoes, instead of soft, smashed potatoes, etc.

The behaviour of the albumin metabolism is the criterion of the severity of the case and of the permanence of recovery. It is possible, he says, to conceive of a functional diabetes in which the centres regulating carbohydrate metabolism do not functionate normally because the internal secretions of the organs involved do not reach them physiologically, owing to lack of development of the organs, or to toxic influences, or other causes. As the young organism grows into harmonious physiologic proportions, things right themselves. This assumption would explain Hürtter's case of apparently complete recovery from severe diabetes in a girl of ten. Lermé (of Nantes) also reported a case of apparently complete cure of a young man of 20, who two years ago presented severe acetonuria and other symptoms of grave diabetes, so that the prognosis was regarded as distinctly unfavourable. What no medical measures had been able to accomplish was realised naturally, probably, by the further development of the organs or centres or both involved.

CANADA.

Toronto, Sept. 28th, 1912.

MEETING OF THE CANADIAN PUBLIC HEALTH ASSOCIATION IN TORONTO.

AMERICA is certainly the country in which conventions are most in vogue and Canada is following in the footsteps of her big sister. There are held conventions of every description, and the medical men are by no means behind hand in contracting the convention habit. Whether or not the holding so many meetings is in the interests of health and the medical profession is a moot point. There are some who think that if less of such meetings took place their loss would not be felt. It is pointed out that many of the papers read are of small account and that really a considerable amount of time is wasted in travelling to and fro. Of course, however, there is another side to the question, meetings give medical men the opportunity of exchanging views, enlarging the scope of their knowledge and mind, and of keeping in touch with all that is latest in medicine and surgery. This is the season for medical conventions. The meeting of the Canadian Medical Association took place recently, the meeting of the Canadian Public Health Association is just over, the American Public Health Association is now holding its meeting, and next week the International Congress of Hygiene meets in Washington, while, at Detroit, the American Hospital Association has its annual session.

Whatever may be said of the plethora of medical meetings on this Continent, there is no doubt that the *raison d'être* for the Canadian Public Health Association is strong. Canada has many health problems to be solved, the chief of which are the safeguarding of

its water supplies, and the best methods of dealing with its large immigration. Both are acutely pending questions. Typhoid fever is continually breaking out in one or another part of the vast dominion, mainly due to polluted water, and the immigrants are unfortunately flocking to the cities rather than to the rural districts where they are most wanted. The influx of Southern Europeans and Italians to the towns has brought about a condition in some of the larger cities and towns almost comparable to that existing in the cities of Europe.

The meeting of the Canadian Public Health Association in Toronto was a success from all points of view. Although only the second meeting since the establishment of the association, it was shown that the association during its short term of life has flourished exceedingly. Already it has more members and larger funds than the American Public Health Association, which has been in existence for forty years. This rapid advance is due to the enlightened policy of those responsible for its management. The general public is urged to take a part in the fight against preventable diseases, and laymen and laywomen are welcomed as members of the association. That they do take great interest in matters relating to public health and have joined the association in large numbers was plainly evident from the attendance. At all the meetings numerous men and women from all ranks of life were present and took part in the discussions. The first paper read was also in many respects the most important. It was by Dr. P. H. Bryce, Superintendent of Immigration, Ottawa, and dealt with the question of how

SHALL CANADA SAVE HER PEOPLE FROM THE PHYSICAL AND MENTAL DEGENERATION DUE TO INDUSTRIALISM as seen in the great cities of older civilisation? He showed that the increased cost of living in Canada was 27 per cent., in the United States 29 per cent., in Germany 40 per cent., and in Great Britain 5 per cent. for the year. He attributed the increased cost to the insane rush to the cities of Canada, both by immigrants and by agricultural labourers. Dr. Bryce asked how long can a country, essentially a producer of raw material by virtue of geographical location and extent of territory still largely undeveloped, continue normally to develop and prosper when it has shown a displacement of rural population during the past ten years never witnessed before in the history of any people, and an increase in urban population, rapid even beyond the palmiest days of United States immigration. Dr. Bryce suggested various means by which people might be drawn back to the land, most of which were of an economic nature.

Another paper read in the same session by Dr. Bruce Smith, Inspector of Prisons and Public Charities for Ontario, consisted for the most part of an

INDICTMENT OF MUNICIPAL HOSPITALS.

That is as they are conducted on this side of the Atlantic. He contended that ward politics were decidedly incompatible with general hospital management, and that the contrast between municipal hospitals and those directed by a local board was most marked. There was always a discordant note from the executive side of the municipal institution. Everywhere were seen the fingers of the politician; the ward boss and the political heeler exerted their baneful influence without check or scruple. Fortunately they had not in Canada the experience which had been so expensive in some American cities during the past few years. Dr. Smith held that the private patient should be permitted to have his own physician or surgeon attend him if he wished; the semi-private patient should have the same privilege if he contributed to the hospital a sum equal to the cost of his maintenance there; the patients in the public wards should be attended by members of the staff. To permit patients in the public wards to have their own medical men would cause endless confusion. Dr. Smith argued that the province of a hospital was not only the treatment and care of the sick, but the instruction of students in the art and practice of medicine and surgery, and the prosecution of scientific research for the welfare of the race.

(To be continued.)

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

RESIGNATIONS OF SOCIETY APPOINTMENTS.—During the past week the resignations of medical officers to clubs have been handed in in a number of districts throughout Scotland. In most cases the resignations have been unanimous. In Edinburgh 116 clubs are involved, and it is believed that every appointment of the kind has now been resigned; in Leith the tale is the same. In Inverness and Fife a similar unanimity prevails. In all the areas in which general resignations to take effect on January 15, 1913, are being handed in, the practitioners concerned are pledged not to accept any appointment so resigned.

SANATORIUM BENEFIT.—There is a very strong feeling among practitioners generally against the appointments of medical officers of health acting as chief tuberculosis officers. It is felt that Public Health officials do not possess the clinical experience requisite for the efficient performance of the duties of tuberculosis officials, and that their attempt to do the work is contrary to the spirit of the Astor Report. The profession also feel that one of the main underlying ideas of the Astor Report—that the duties of a tuberculosis officer in relation to the general practitioner are essentially consultative—is likely to be frustrated should the work fall into the hands of medical officers of health, who would tend to deal with tuberculosis as they deal with the infectious fevers and take it entirely out of the hands of the practitioners. Indeed, this is no idle fancy, because it is known that the avowed intention of one Scottish County Medical Officer of Health is to treat every case of tuberculosis in a sanatorium, and to discourage domiciliary treatment altogether. The Scottish Local Government Board is known to favour the entrusting of the duties of chief tuberculosis officer to the M.O.H., and in certain official quarters the idea of domiciliary treatment is deprecated on the ground that a working man's home cannot be rendered suitable for treating a case of tuberculosis. Other M.O.H.'s hold opposite views, and we have it asserted equally definitely that sanatoria are needed little, if at all, but that what is required is a Tuberculosis Dispensary. The fact is that Medical Officers of Health have not the clinical experience necessary to prevent them falling into the error of generalising. Tuberculin is all very well in its way, but its wholesale use at a dispensary will not cure tuberculosis. Sanatoria are most valuable, but not every case needs them. The general problem of tuberculosis is one thing; the treatment of the tuberculosis patient another. We take it that the duties of the M.O.H. begin and end with administration—with questions of housing, of infection, of disinfection, and the like; the treatment of tuberculosis should remain in the hands of the clinician—that is to say, the general practitioner supported by an expert in the diagnosis and treatment of the disease. By this means, not by any wholesale institutional or tuberculin treatment will sufferers get the best chance of cure.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE POSITION OF DENTISTRY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I ought to have thanked you in my last letter for the admirable leader on the above-named subject in your previous issue. You have there supplied an absolutely clear statement of the case upon which was based the claim for the legislation which, through the Dentists Act of 1878, gave to dentistry a position as a medical speciality under the government and control of the General Medical Council. Since the greater includes the less, it was inevitable that with the overthrow of that part of medical law which was designed to protect the public, the corresponding, and similarly worded, clauses in the Dentists Act would be sooner

or later discovered to be inoperative; and, as you have pointed out, there now remains no legal check upon the false pretences of unqualified pretenders or fraudulent quacks in any department of practice they may choose to take up. The Dentists Act in this direction was bound to go. The pity is that the British Dental Association did not bring the question to a final issue in the law courts twenty-five years ago, or as soon after 1878 as violations of the spirit of the Act began to be common. If the weakness of the then new legislation had been at once exposed, and confirmed by the High Court and the House of Lords, an amending Act to repair the weakness of the statute might have been demanded with reason. The Dental Association showed lamentable weakness all along. It was always evidently willing to wound and yet afraid to strike. Unqualified practice increased, with increasing boldness in use of language in advertisements implying possession of a legal qualification; and finally, about twenty years ago, the late Mr. Labouchere, in *Truth*, gave the *coup-de-grace* to the dwindling respect in which the law was regarded by unregistered men. I am reminded of this episode by your leader on *Truth* in your current number. It might be amusing, if not instructive, to learn what the present Editor has to say about it. The Dentists Act was accepted by Parliament because it had been incontrovertibly demonstrated that the uneducated dentist was only one degree less harmful to the public than were his brethren practising in other departments as specialists of medicine, and that he was less harmful only because his powers were more limited; he did not often deal with issues of life and death. These facts and considerations were to its own satisfaction proved by *Truth* to be mere "flapdoodle bunkum and hypocrisy." The ideal dental practitioner was the inventor of the "guinea jaw, warranted for five years," and after a series of articles on the subject, the late Mr. Labouchere ended by giving his personal testimonial to the proprietors of this invention. This testimonial was advertised for years, and no doubt made the fortune of its possessors. This formed a sort of apotheosis for the unqualified dentist, and it was not to be wondered at if a crowd of men of the type you have described took the hint so forcibly pressed on their notice.

As I pointed out in an earlier letter, there are now more unqualified men than qualified men practising dentistry. The unqualified vary between honest, albeit mostly ignorant, mechanics and unscrupulous men out only for plunder. Some of these men work under the cloak of companies or bogus institutions with fine-sounding names. These establishments are worked by unqualified assistants. It is well known that these men receive small salaries, but large commissions on the receipts. The aim is, therefore, to get as much money out of each patient as possible, and consideration of the welfare of the patient takes a second place. The cruel character of a great deal of quack dental practice is well known to every legitimate practitioner of sufficient experience, and is exemplified daily among hospital patients. The victims are mostly women—wealthy, foolish ones among the higher ranks, simple, confiding and helpless victims among the lower.

I am, Sir, yours truly,

A HOSPITAL DENTIST.

October 2nd, 1912.

SOMETHING BEYOND INSURANCE REMUNERATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Sir Victor Horsley, in his speech at Appleby on September 26th, refers to the difficulty between the Chancellor of the Exchequer and the medical profession as being "merely a question of remuneration for work done."

Undoubtedly the question of remuneration is a very important one, but it is by no means so all-engrossing to the medical profession as has been represented. There are many other points in the medical clauses of the Insurance Act to which objection is taken, the chief opposition of the profession to the Act being on

account of its inefficiency as a measure for improving the public health.

One of the principal demands of the profession is for adequate representation on the local Insurance Committees. A perusal of the lists which have been published giving the *personnel* of these Committees amply demonstrates the necessity for this demand. It will be of interest to medical men, and possibly also to the general public, to study the composition of these Committees to which it is proposed to give so much power. Copies of the lists may be obtained from Messrs. Wyman, Fetter Lane, E.C., at the price of 1d. each.

It is imperative that the public should realise that adequate remuneration is not the only principle for which the profession is fighting. It should also be understood clearly that in this fight the interests of the doctors and of the public are identical, a good and efficient medical service being a necessity to the nation; but this efficiency cannot be attained under ignoble conditions.

I am, Sir, yours truly,

J. WEBSTER WATTS,

Secretary, National Medical Union.

5 John Galton Street, Manchester.

October 2, 1912.

A QUESTION OF AUTHORSHIP.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having just had for the first time the opportunity of reading Dr. Claye Shaw's lecture in your issue of August 21st, I find him crediting Charles Lamb with the following lines:—

"Is it a party in a parlour,

Crammed just as they on earth are crammed?

Some sipping punch, some drinking tea,

And by their faces, as you see,

All silent and all dauned."

But to the best of my recollection, the author of them was none other than the poet Wordsworth, who, however, saw fit to omit them from any except the first edition of the poem of which they form a part. I doubt whether the admirers of either poet will be eager to claim them.

I am, Sir, yours truly,

DUNDAS GRANT.

18, Cavendish Square, London.

October 3rd, 1912.

OBITUARY.

DR. E. WOAKES, OF FAREHAM.

WE regret to announce the death of Dr. Edward Woakes, of Wimpole Street, London, and Belvoir House, Fareham, Hants., which took place on the 30th ult., in his 76th year. The deceased, who was well known as an aurist and laryngologist, qualified as M.R.C.S. and L.S.A. in 1858, becoming M.D.Lond., in 1863. He was formerly House Surgeon at St. Thomas's Hospital. He then joined his father at Luton in general practice, founding Luton Cottage Hospital, now known as the Butc Hospital. Returning to London in 1876, he decided to specialise in diseases of the ear, nose and throat. He was appointed Aural Surgeon to the London Hospital and Lecturer in Aural Surgery in the Medical School, and he was also attached to the staff of the Golden Square Throat Hospital. Dr. Woakes assisted in founding the London Throat Hospital in Great Portland Street. His treatment for adenoids and nasal polypus marked a considerable advance on previous methods, and he wrote on nasal diseases and kindred subjects. Dr. Woakes' connection with Fareham commenced in the year 1894. He took a lively interest in local affairs, connecting himself with many social and philanthropic institutions. In politics he was a Liberal, and among the positions he held were Vice-Presidencies of the South Hants Liberal Association and the Fareham Liberal Association. Owing, however, to his serious illness he had not been able to take a very prominent part in the life of the town during the last year. His

wife died in 1909. One of his sons continues his father's practice.

DR. E. M. LIGHT.

THE death took place at Croner on October 1st, of Dr. Edwin Melloi Light, of Ebury Street, Eaton Square, S.W., chief Medical Officer of the Prudential Assurance Company, in his 52nd year. Dr. Light, who received his medical education at Cambridge, Leeds and St. Thomas's Hospital, qualified as L.R.C.P.Lond., in 1887, becoming M.R.C.S. in 1889. He graduated M.A., M.B., B.C.Cantab. in 1887-8. He obtained an exhibition at St. Thomas's Hospital for proficiency in natural science, and he afterwards held the post of Clinical Assistant in the Throat Department at St. Thomas's. He then held other appointments at the Hospital for Women, Soho Square, the Brompton Hospital for Consumption, and he was formerly resident medical officer, pathologist and house physician at the Leeds General Infirmary. Dr. Light was a well-known figure in the insurance world, being a member of the Life Assurance Medical Officers' Association as well as the Association Internationale des Médecins Experts de Compagnies d'Assurance.

SPECIAL REPORTS.

THE IRISH INSURANCE COMMISSIONERS AND THE MEDICAL PROFESSION.

IN THE IRISH SUPPLEMENT TO THE MEDICAL PRESS AND CIRCULAR of last week, we found it our duty to comment on both the manner and matter of an interview granted by two of the Irish Insurance Commissioners—the Chairman, Mr. Glynn, and Dr. Maguire—to a representative of the *Irish Times*. We singled out a few of several misrepresentations made by the Commissioners with regard to the attitude and demands of the medical profession. Mr. Glynn has now thought right to reply to our criticisms in another interview granted last Saturday to a representative of the *Irish Times*. As Mr. Glynn attempts to defend some of his misrepresentations, it is necessary again to consider his arguments. We had been charitable enough to hope that some of the more manifest blunders of the first interview were due to the reporter rather than to the Commissioners; but Mr. Glynn states now that the report of the first interview "was accurate in every particular."

"The interview was given," he goes on, "after full consideration of my position as a civil servant and chairman of the Commission." We disagree with Mr. Glynn's views as to the propriety of civil servants giving interviews, especially for the discussion of controversial points; but what is more important is that, neither before nor since the publication of the first interview has he taken the care to verify the statements then made.

In the first place, Mr. Glynn discusses the demand which he said was made by "the doctors" of a payment of 3s. per head of all insured persons to cover the cost of certificates. We pointed out that this demand was never made by any representative body of the profession, and, in fact, was repudiated by the first representative meeting of the profession which heard of it. Mr. Glynn admits now that it was made by certain medical members of the Advisory Committee, whom he designates "representatives of the Conjoint Committee on the Advisory Committee." The members of the Advisory Committee are, as everyone knows, nominated by the Commissioners. But whatever may have been the authority for the demand when made, it is now obsolete, and in reviving it Mr. Glynn goes against his own statement that "the object of the interview was not to endeavour to place the doctors in the wrong."

He next comes to the statement of the Commissioners that a fee of 7s. 6d. was demanded by the Dublin Medical Committee for, as he puts it, "introducing a patient to a tuberculosis dispensary"—viz., "2s. 6d. for a certificate and 5s. for a report." Mr. Glynn does not yet see his blunder. As the Commissioners have issued regulations which require a claimant for sana-

torium benefit to present a full medical report on a specified form, and do not in any case require a separate certificate, the fee for the latter disappears, and the fee that remains—*gs.* for the report—has been sanctioned by the Commissioners.

In the first interview the Commissioners were reported as making one statement so wild that we charitably thought their remarks had been misunderstood by the reporter. We were wrong. The statement ran: "Throughout the country there were several instances of doctors being prepared to act on the terms laid down by the British Medical Association, but they were afraid to do so, lest they should be struck off the *Medical Register*." Mr. Glynn supports this absurdity as follows:—"I can only refer to the meeting of the Dublin medical practitioners, presided over by the President of the Royal College of Surgeons, and reported in the June number of the *Journal* of the Irish Medical Association. The third resolution is as follows:—"That a 'black list' be formed, on which the name of every practitioner who refuses to sign the pledge will be placed. This to be published in the Medical Colleges; and it is understood that everyone who appears thereon shall be boycotted by means known to the medical profession."

Even had a resolution in such terms been passed, it would give no support to the statement made by the Commissioners. But we can assure Mr. Glynn and our readers that no resolution in such terms was passed at any meeting of the practitioners of Dublin.

Mr. Glynn finds fault with our remark that the profession in Ireland has always been anxious to help in the administration of the sanatorium benefit. He says that "co-operation is only offered on condition that the terms of the medical profession be accepted." The point is a niggling one. What the profession demands is that the benefit should be run upon such lines as can be approved by the profession, and, as we pointed out, medical members of the various insurance committees are at present performing their unpaid duties with regard to the sanatorium benefit with zeal and discretion. How long they can continue to do so is a matter for the Commissioners.

Discussing domiciliary treatment under the sanatorium benefit, Mr. Glynn says:—"The point that seems to have been lost sight of by the medical profession is that domiciliary treatment was not really part of the original plan connected with the scheme, and was inserted to meet the wishes of the profession, which complained that there was a danger of local medical practitioners having their private patients taken from them." So far from our having lost sight of this point, we never saw it before. What is "the original plan" of which Mr. Glynn speaks? Where can it be seen and studied? Where and when did the profession make the alleged complaints? Is there anything in domiciliary treatment alien to the clauses of the Insurance Act, which speaks of "treatment otherwise than in sanatoria or other institutions?" Reference is made to domiciliary treatment side by side with other forms of treatment in the various papers issued by the Irish Commissioners—*e.g.*, Form Med. 2, Memo. No. 112/I.C. Moreover, the Interim Report of the Departmental Committee on Tuberculosis, which is generally regarded as laying down the lines on which sanatorium benefit should be administered declares:—

"[Par. 28]. The following conditions are essential . . .

"(3) In the case, at all events, of insured persons, patients living at home who are treated at or under the supervision of the dispensary should generally be placed, where they are willing, under the care of some general practitioner who will carry out the necessary home treatment in consultation with the chief tuberculosis officer of the dispensary, and who will, where the patients are insured persons, be paid out of the funds available for sanatorium benefit."

We find, therefore, that what the Departmental Committee regard as an essential, is, according to the Chairman of the Irish Insurance Commission, "not really part of the original scheme," but something "inserted to meet the wishes of the profession!" We hesitate to assume that Mr. Glynn, like the man in the

street, has fallen into the error of regarding the statutory term "sanatorium benefit" as meaning benefit of or treatment in a sanatorium, and that, therefore, treatment outside a sanatorium is "not really part of the original scheme."

Mr. Glynn concludes:—"The charge that my action tends to hamper the administration of the Act is ridiculous, because all I have done is to do some sums in arithmetic, the results of which have evidently greatly displeased the MEDICAL PRESS."

We are not at all concerned with Mr. Glynn's arithmetic as a mental exercise. He had, however, chosen to compare figures which cannot honestly be compared. We repeat our criticism of last week:—

"In order, further, to cast ridicule on the suggestions of the Dublin Committee, the Commissioners contrast the sums required to deal with the *insured and their dependents* if the suggestions were adopted, with those required to deal with the *insured alone* on their own scale of fees. Naturally there is a considerable difference, but the argument is hardly honest."

We have no option but to conclude as before "that this interview has done more to hamper the administration of the sanatorium benefit in Ireland than any single incident since the Bill was introduced to the House of Commons."

At the same time, while regretting Mr. Glynn's impotence in his errors, we are glad to note that the tone of his second interview is hardly as truculent as that of his first. We may add that there are other fallacies in his statement than those on which we have commented, and that we shall have to return to the subject at an early date.

REVIEWS OF BOOKS.

CEREBRAL DECOMPRESSION. (a)

ALL medical men regard with satisfaction the extraordinary advance in abdominal surgery during recent years, but they do not usually consider the fundamental reasons for surgical success in this region, nor apply their conclusions to the surgery of other parts of the body. Early diagnosis, the evacuation of abscesses, palliative measures, which by their adoption have done so much for the treatment of abdominal disease, have, in the hands of a few, produced great improvements in the treatment of intracranial lesions. We welcome this short address on the possibilities afforded by a timely decompression operation. The arguments presented are essentially sound, and should be instinctively appreciated by the general practitioner, as well as by the surgeon. The author points out that too many cases of cerebral tumour are allowed to progress to inevitable agony, blindness, and death, when it is in the power of the average competent surgeon to relieve the symptoms, if not to eradicate the disease. The author has certainly made an effective point and one worthy of wide-spread acceptance. The cases quoted with regard to decompression operations for apoplexy are highly suggestive, and ought to make us more inclined to give these patients a chance of relief before paraplegia becomes permanent. The results of drainage in purulent basal meningitis seem to warrant more active treatment than has been the custom in the past. This book fulfils a distinct need for the practitioner, and is a most excellent guide to the treatment of intracranial lesions.

ELEMENTS OF PRACTICAL MEDICINE. (b)

WE believe in the short text-book as a means of giving the student a bird's-eye view of his subject before he embarks on the study of greater detail. Professor Carter's little book will serve as an admirable introduction, and it must be a matter of personal opinion regarding what is to be included and what left out. For our own part, we think the space occupied by the opening section on general pathology

(a) "Cerebral Decompression in Ordinary Practice." An address by Charles A. Ballance. Pp. 71, illustrated. London: Macmillan and Co. Price 2s. 6d. net.

(b) "Elements of Practical Medicine." By Alfred H. Carter, M.D. Tenth edition. Pp. 683. London: H. K. Lewis. Price 9s. net.

might have been better employed. Most readers of this book will have already passed an examination in pathology demanding a greater knowledge than the section imparts. We should also have preferred that the therapeutic index at the end of the book had been embodied in the text. In its isolated position it may either be overlooked or used for cramming purposes. But criticism stands disarmed before a tenth edition.

NEW PHYSIOLOGY IN SURGICAL AND GENERAL PRACTICE. (a)

At first blush it would appear unfortunate that such a work as this should be necessary, but a glance through current physiological literature suffices to convince one that it is not the sort of reading that the busy practitioner is likely to take up and digest for himself.

Dr. Rendle Short is in the position of having a first-hand knowledge of physiological progress and of the demands of practice. He has, further, the gift of clear exposition, so that he has been able to place in the hands of practitioners an account of recent physiological work which is likely to stand him in good stead, and by applying physiological advances to practice he also indicates directions in which further physiological inquiry is desirable.

Sir William MacEwan's views on growth of bone are clearly set forth, and there seems little doubt that the theory that periosteum has an osteogenic function must be revised. There are useful chapters on shock, the internal secretions, digestion, chloroform poisoning, diabetes, acidosis and nerve injuries. We welcome the statement that sedative drugs applied to the unbroken skin are useless except as wet dressings.

From the point of view of the physiologist, the criticism might be made that the information on some topics is rather meagre, and the reader will certainly interject a good many "whys" after some rather dogmatic sentences; but, after all, the early appearance of this edition is clear evidence that the book is one the practitioner wants.

Among minor criticisms we might note that on page 29 we are told not to repeat a dose of pituitary, but no explanation is forthcoming till page 64 is reached. "Resuscitation" would be, on many grounds, a better term than "resurrection" on page 21. The reader might be entrusted with the formula for Ringer's solution (p. 31). Sweetbread (p. 120) is thymus, not pancreas, although it may be defined differently by a slum butcher.

On page 164 the author declines to explain the terms "A.C.C." and "K.C.C.," "because only an expert would undertake the investigation of the electrical reactions." We should be sorry for a student who could not define them in his professional examination, either in physiology or in medicine.

Altogether this is a most useful and readable little book, and we hope that there will be both a demand for and a supply of further editions, which will enable the practitioner to utilise to advantage the stream of energy constantly flowing from our scientific laboratories.

PSYCHOLOGICAL MEDICINE. (b)

In this book we have a good account of psychological medicine in reasonable bulk. Due respect is paid to authority even when it does not accord with the author's experience, and little fault is likely to be taken with the treatment of any part of the subject. The chapter on the relationship of insanity with law and that on treatment are particularly good, although we find no guidance as to the management of seizures in general paralysis.

We take exception to the author's statement that reflex actions have no psychological concomitants, and that they are all carried out by the lowest level of the nervous system. It would be more in accord with modern physiology to say that reflexes may pass through any part of the nervous system, the presence or absence of psychical concomitants being a matter

of accident as far as the reflex action is concerned. The book is well worthy of better revision than it seems to have received. In the first place, while subdivision into paragraphs has ensured completeness, there is a good deal of unnecessary repetition, which the recurrence of such phrases as "the scaffolding upon which the mind of man is built" serves to emphasise. Most irritating is the frequent reference to matters treated elsewhere. A note of chapter or page would have been a graceful concession to the reader.

There is a good deal of careless writing. We may instance a number of ruthlessly split infinitives, and (p. 226) "at the risk of being thought tedious, the student may be reminded."

We note a fair crop of printer's errors.—P. 92, heart palate; p. 175, "Frequent pregnancies . . . may terminate insanity"; p. 235, *Rhomberg*; p. 312, *Huntingdon's* chorea; p. 329, *aphasisas*; p. 409, *recrod*. We have pleasure in recommending the book, and such minor blemishes as we have noticed will not detract from its value to those who use it as a textbook or work of reference. There are several beautiful plates.

FIRST-YEAR NURSING. (a)

This book on first-year nursing, by an American author, should be a great help to probationers during their training, and is especially good in that it aims solely at giving instruction in *nursing*, not in medicine and surgery watered down to suit the supposed requirements of the nurse, a most common fault in many nursing manuals. With this book to refer to, much that is puzzling to understand in what is done around her during the early days of her training will become clear to the young nurse, and its admirable instructions on various points of ethics and etiquette ought to save her from many a *faux pas*. Chapter XIV. on Observation of Symptoms, is a valuable one, deserving of careful study, for no nurse can be a reliable help to a doctor unless she is a shrewd observer and cultivates the power of putting her observations into clear words. We can heartily recommend the book to all probationers who are anxious to make the best use of their time in hospital.

MEDICAL NEWS IN BRIEF.

The Entrance Scholarships at the Medical Schools.

The two University entrance scholarships of the St. George's Hospital Medical School have been awarded as follows.—Scholarship of 70 guineas—Rhys Trevor Jones (University College, Cardiff); scholarship of £50—Tom S. Nelson (University College, Oxford).

The Goldsmid Entrance Exhibitions in Anatomy and Physiology for the winter session at University College Hospital Medical School have been awarded to Mr. M. S. Woolf, M.A., Birmingham University, and Mr. W. T. Collier, B.A., Balliol College, Oxford.

The following Entrance Scholarships and Prizes have been awarded at Guy's Hospital Medical School:—

Senior Science Scholarship for University Students.—(£50), C. P. Symonds, New College, Oxford. Junior Science Scholarships.—£120, J. E. E. de Robillard (Preliminary Science Class, Guy's Hospital); and £60, H. J. Bensted, Birkbeck College, and J. C. C. Howe (Preliminary Science Class, Guy's Hospital), equal. Entrance Scholarships in Arts.—£100, W. H. Steavenson, Cheltenham College; and £50, F. R. Leblanc, Royal College, Mauritius.

The following entrance scholarships have been awarded at the Middlesex Hospital Medical School:—University Scholarship, S. D. Kilner; First Entrance Scholarship, J. D. Dyson; Second Entrance Scholarship, F. C. Mason; Third Entrance Scholarship, E. H. Lake; Freer Lucas Scholarship (Epsom Col-

lege), W. B. Gabriel; New Zealand Scholarship, W. P. Johnston.

The Middlesex Hospital Medical School Awards.

THE following is a list of the awards of the Entrance Scholarships made at the opening of the winter session at this school last week:—University Scholarship, S. D. Kilner; First Entrance Scholarship, J. D. Dyson; Second Entrance Scholarship, F. C. Mason; Third Entrance Scholarship, E. H. Lake; Freer Lucas Scholarship (Epsom College), W. B. Gabriel; New Zealand Scholarship, W. P. Johnston.

Central Midwives Board.

A MEETING of the Central Midwives Board will be held at the Board Room, Westminster, to-morrow (Thursday), immediately on the termination of the proceedings of the Finance Committee summoned for that day, when reports of the various standing committees will be read, and, among other business, a letter from the Lord of the Council will be read, fixing the scale of the present Secretary's salary at the following rate:—£600, by annual increments of £25 to a maximum of £750; to take effect from April 1st, 1912.

University of Cambridge.

DIPLOMA in Tropical Medicine and Hygiene.—The following candidates, having satisfied the examiners, are entitled to receive the diploma:—J. F. Corson, G. I. Davys, G. G. El-daba, C. A. Gourlay, J. E. L. Johnston, W. Lapsley, W. F. M. Loughnan, F. C. McCombie, A. C. N. McHattie, A. R. Neligan, A. H. Owen (Caius), P. M. Rennie, H. E. Smith, B. Spearman (Caius), C. J. Stocker (Trinity), C. L. Strangman, and W. Telfer.

Epsom College Speech Day.

EPSOM College Speech Day, which had been postponed from July 27, was celebrated on Saturday, when the Lord Mayor of London, who was accompanied by the Lady Mayoress and the Sheriffs, attended to distribute the prizes. Before the distribution the visitors were entertained at luncheon, Sir William Church, Bart., chairman of the council, presiding.

The Headmaster, the Rev. T. N. H. Smith-Pearse, in proposing the toast of "The Lord Mayor and Sheriffs," said they had all been most anxious that the first time a member of the medical profession held the great office of Lord Mayor of London he should be invited to Epsom College, which was closely connected with the medical profession.

The Lord Mayor, in replying, said he felt when he accepted the office of Lord Mayor that anything he could do to lift up his profession should be done. If he had not been a medical man he should have hesitated before he accepted the position, and should finally have decided not to accept it. But he felt he should like the whole world to know that medical men could attend the Council Chamber and advise in the position of Chief Magistrate.

The Hospital Saturday Fund.

AT the quarterly meeting of the Board of Delegates of the Hospital Saturday Fund, held on Saturday evening at the offices, Gray's Inn Road, Mr. Harry Gower presiding, it was reported by the secretary (Mr. A. W. Davis) that the receipts to date had amounted to £18,320, a decrease of £271 upon last year at the same period. Arrangements have been completed for the annual collection on Saturday next, the 12th inst.

Plague in the Azores.

A SEMI-OFFICIAL note declares the existence of bubonic plague at the Angra Do Heroismo islands in the Azores. The Government have decided to send from Lisbon some serum and also, if necessary, hospital helpers and nurses. The Minister for Foreign Affairs will officially communicate to all foreign nations the existence of plague at Angra.

London—Bath Spa Express.

A NEW service to Bath, specially designed for the comfort and convenience of visitors to that well-known health resort, was inaugurated on October 1st, when

the first journey was made of the "Bath Spa Express." The express leaves Paddington every morning at eleven o'clock, accomplishing the journey to Bath in one hour and three-quarters, a non-stop run through the beautiful scenery of the Thames Valley and across the Wiltshire Downs. For the convenience of invalids, we are asked to state that seats may be reserved in advance, and a stewardess is carried to attend to the comfort of ladies travelling to Bath for the cure. Bath has been very much before the medical profession and the public lately, and facilities afforded by such a train for easy and luxurious travel, will be appreciated by cure-guests to the historic health resort.

The Naval Medical Service.

AT the examination for the Naval Medical Service held on September 30th and October 1st, 2nd, and 3rd, ten candidates were successful and obtained the following marks:—Mr. A. E. Malone, 1,663; Mr. H. M. Whelan, 1,558; Mr. R. F. P. Cory, 1,543; Mr. H. St. C. Colson, 1,503; Mr. P. L. Gibson, 1,485; Mr. G. A. Finegan, 1,390; Mr. F. St. B. Wickham, 1,285; Mr. J. T. D. S. Higgins, 1,258; Mr. J. B. Boal, 1,208; Mr. S. Punch, 1,200. The possible number of marks for the examination was 2,400.

Royal College of Surgeons of England.

THE following demonstrations of specimens in the Museum will be given in the Theatre of the College on the dates named. The demonstrations are intended for advanced students and medical practitioners:—

Friday, October 18th, 5 p.m. Prof. Arthur Keith: Specimens recently added to the Museum—(1) Skeleton of a boy who suffered from the disease described by Mr. Hastings Gilford under the name of progeria. (2) Skeleton of a child the subject of infantilism (ateliosis). Other specimens of surgical interest exhibiting defective growth.

Monday, October 21st, 5 p.m. Mr. S. G. Shattock: Specimens illustrating diseases of the genito-urinary organs.

Wednesday, October 23rd, 5.30 p.m. Mr. J. F. Colyer: John Hunter's specimens illustrating the formation and growth of teeth.

Friday, October 25th, 5 p.m. Prof. Arthur Keith: Specimens recently added to the Museum—Specimen illustrating the result in a case where the condition of imperforate anus was relieved. Specimens illustrating the comparative anatomy of the prostate. Sexual organs of eunuchs; undescended testicles.

Monday, October 28th, 5 p.m. Mr. S. G. Shattock: Specimens illustrating diseases of the genito-urinary organs.

Wednesday, October 30th, 5.30 p.m. Mr. J. F. Colyer: John Hunter's specimens illustrating the natural history of the human teeth.

Friday, November 1st, 5 p.m. Prof. Arthur Keith: Specimens illustrating the comparative anatomy of the cæcum and appendix; of the gall-bladder; of the thyroid; and of the tonsil.

Monday, November 4th, 5 p.m. Mr. S. G. Shattock: Specimens illustrating diseases of some of the ductless glands.

Wednesday, November 6th, 5.30 p.m. Mr. J. F. Colyer. Specimens illustrating pericardial disease (pyorrhæa alveolaris) as seen in man, wild animals in captivity and domesticated animals.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Royal Faculty of Physicians and Surgeons of Glasgow.

THE following candidates having passed the requisite examinations of the above Board in October, were admitted Diplomates in Public Health:—Edward L. Middleton, Alexandra B. MacCallum, John D. Ingram, John C. MacCallum, Dewan Jai Chand, William G. Macdonald, Kate Fraser, Jane H. McIlroy, George C. Strathairn, Daniel C. Adam, Alexander J. Ewing, George V. T. McMichael, and Peter Allan.

SURG.-GEN. L. E. ANDERSON has been appointed Deputy Director of Medical Services, Irish Command.

NOTICES TO CORRESPONDENTS, &c.

✎ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature* or *Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

A FRAGMENT.

THERE is nothing like following out the doctor's orders. The Doctor said to Mrs. Perkins, whose husband was lying ill:—

"Has he had any lucid intervals?"
Mrs. Perkins replied at once: "E's 'ad nothin' except what you ordered, Doctor."

DR. W. M. (Hunts).—The question you raise cannot be finally settled until the profession is more unanimous with regard to the propriety of having pay-wards in general hospitals at all. We do not think that the mere giving of a donation upon discharge brings the donor into the category of a "paying patient."

THE HEALTH OF NEWCASTLE-UPON-TYNE.

ACCORDING to the thirty-ninth annual report of the Medical Officer of Health of the City and County of Newcastle-upon-Tyne, Dr. Henry-E. Armstrong, the death-rate (uncorrected) of Newcastle from "all causes" during the year 1911 was 17.5 per 1,000 population. The corrected rate is 16.4. The population of the city shows a decrease of 18,690, as compared with that of the previous year, which has the effect of increasing the general rate of mortality (uncorrected) by 1.2 per thousand. The death-rate from the chief zymotic diseases was 1.83 per 1,000 population, as compared with 2.27 for the 77 largest English towns. The purity of the milk-supply has received much attention from the staff of the Health Department, and the city is to be congratulated in being controlled by an energetic Sanitary Committee, which have always consistently supported the actions and proposals of their Medical Officer.

THE MAN OF THE FUTURE.

WE are all familiar with housemaid's knee, the lawn-tennis elbow, the bicycle glare, and rubber neck, and now we are making acquaintance with the motor-bus spine, which is a jumbled condition of the vertebrae. When he has acquired all these and one or two more, the man of the future will indeed be a thing of beauty.—*Sketch.*

Meetings of the Societies, Lecturs, &c.

WEDNESDAY, OCTOBER 9TH.

UNITED SERVICES MEDICAL SOCIETY (Royal Army Medical College, Grosvenor Road, S.W.).—5 p.m.: Fleet-Surgeon Bassett-Smith, C.B., R.N.: Presidential Address. Captain Sylvester-Bradley, R.A.M.C.

HUNTERIAN SOCIETY, London Institution (Finsbury Circus, E.C.).—8.30 p.m.: Council Meeting.—9 p.m.: Dr. F. Taylor.

THURSDAY, OCTOBER 10TH.

NORTH-EAST LONDON CLINICAL SOCIETY (Prince of Wales's Hospital, Tottenham, N.).—4.15 p.m.: Sir J. Rose Bradford, Opening Address.

ROYAL SOCIETY OF MEDICINE (OBSTETRICAL AND GYNECOLOGICAL SECTION) (1 Wimpole Street, W.).—8 p.m.: Cases and Specimens by Dr. Maxwell and Dr. Henry Briggs (Liverpool). Paper by Dr. Thomas Wilson (Birmingham): Gelatinous Glandular Cysts and the so-called Pseudomyxoma of the Peritoneum.

FRIDAY, OCTOBER 11TH.

ROYAL SOCIETY OF MEDICINE (OBSTETRICAL AND GYNECOLOGICAL SECTION) (1 Wimpole Street, W.).—8.45 p.m.: Special General Meeting of Fellows. (1) To Ballot for the following Candidates for Fellowship: Rachel Nathaniel Cohen, M.B., F.R.C.S.I.; William Edwin Haigh, F.R.C.S.; Gerald Herbert Johnston, L.R.C.P., L.R.C.S.; Stephen George Longworth, L.R.C.P.; William Love, F.R.C.S.I.; Robert Barclay Ness, M.B., C.M.; Raymond Broadley Etherington Smith, M.B., B.C., F.R.C.S.; James Greig Soutar, M.B., C.M.Ed.; Frank Pearce Sturm, M.Ch., M.B.; Margaret Grace Thackrah, M.B., B.S.; Richard Thorne Thorne, M.D., B.S. (2) To consider a Resolution, proposed by the Council, with regard to the naming of rooms in the new House.

ROYAL SOCIETY OF MEDICINE (CLINICAL SECTION) (1 Wimpole Street, W.).—8.30 p.m.: Cases by Dr. A. M. Goswage, Dr. H. Morrison Davies, Dr. W. P. Herringham, and Dr. F. Parkes Weber.

MONDAY, OCTOBER 14TH.

MEDICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—8 p.m.: General Meeting.—8.50 p.m.: The incoming President, Sir W. Watson Cheyne, Bt., O.B., F.R.S., will deliver the introductory address, to be followed by a paper by Dr. T. J. Poynter and Dr. H. O. J. Pedler, on "A Case of Anemia of the Pernicious Type with Acholuric Jaundice."

Appointments.

- GREEN, EDWIN, M.R.C.S., L.R.C.P., a Medical Referee under the Workmen's Compensation Act, 1906, for County Derbyshire, Court Circuit No. 19.
GREENE, ANNIE C., M.B., Ch.B.Edin., Resident Medical Officer to the Blackburn Union.
MACNAMARA, J., L.R.C.P., and S.Edin., L.F.P.S.Glas., Certifying Surgeon under the Factory and Workshop Acts for the Bellanagh District of the county of Cavan.
MAPLETON, HENRY BANBURY, M.D., C.M.Edin., D.P.H.Lond., Medical Officer of Health by the Newton Abbot (Devon) Rural District Council.
MURPHY, CHRISTOPHER FRANCIS, L.R.C.P., L.R.C.S., L.M.Irel., Medical Officer for the North Chardstock District by the Axminster (Devon) Board of Guardians.
SEALY, ARTHUR LESLIE MARMADUKE, M.B., C.M.Aberd., Medical Officer for the Ilplepen District by the Newton Abbot (Devon) Board of Guardians.
VYSSELOVSKY, VICTOR C., M.R.C.S., L.R.C.P., House Surgeon at the Hampstead General and North-West London Hospital.
WOOLF, A. E. M., M.B.Cantab., F.R.C.S.Eng., Medical Referee under the Workmen's Compensation Act, 1906, for County Court Circuit No. 58. to be attached more particularly to Tavistock and Okehampton County Courts.

Vacancies.

- Hants County Asylum.—Third Assistant Medical Officer. Salary £200 per annum, with furnished apartments, board, washing, and attendance. Applications to the Visiting Committee, Hants County Asylum, Fareham.
Warwick County Asylum.—Second Assistant Medical Officer. Salary £175 per annum, with board, apartments, and laundry. Applications to Dr. Miller, Hatton, Warwick.
Royal Victoria Infirmary, Newcastle-upon-Tyne.—Resident Medical Officer. Salary, £200 per annum, with board and residence. Applications to the House Governor and Secretary, Royal Victoria Infirmary, Newcastle-upon-Tyne.
Ecclesall Bierlow Union.—Resident Assistant Medical Officer. Salary £200 per annum, with board, washing, and furnished apartments. Applications to J. E. Moulding, Clerk to the Guardians, Union Offices, "The Edge," Sheffield.
Gordon Hospital, Vauxhall Bridge Road.—House Surgeon. Salary £50 per annum. Applications to C. St. Amory, Secretary. (See advt.)

Births.

- BURGESS.—On Sept. 18th, at 10 Riggindale Road, Streatham, the wife of Dr. H. Lynch Burgess, West African Medical Service, of a son (Gerald).
GOODING.—On Oct. 3rd, at Ashton Lodge, South Norwood, Edith, the wife of Simonds Gooding, M.D., M.A. (Cantab.), of a son.
HANWELL.—On Oct. 2nd, at 40a Hyde Park Gate, S.W., the wife of Gerald Hanwell, M.R.C.S., Eng., L.R.O.P.Lond., of a son.
RAIT.—On Sept. 30th, at "Woodstock," 22 Lyndhurst Gardens, Hampstead, N.W., the wife of Major J. W. F. Rait, I.M.S., of a daughter.

Marriages.

- GREEN—COWAN.—On Oct. 1st, at St. Peter's, Brockley, Charles David Green, M.D.Lond., F.R.C.S.Eng., of Romford, to Gertrude, youngest daughter of Demetrius and Louisa Cowan, of Wickham Road, Brockley.
HERTZ—RIDDIFORD.—On Oct. 2nd, at St. Thomas's, Portman Square, Arthur Frederick Hertz, M.D., F.R.C.P., youngest son of the late William M. Hertz, of Bradford, and Bowden, Cheshire, to Cushla, youngest daughter of the late Frederick Riddiford and of Mrs. Riddiford, of New Zealand.
LEA-WILSON—LUTMAN.—On Sept. 30th, at the Church of St. John Baptist, Pinner, Basil H. C. Lea-Wilson, M.R.C.S., L.R.C.P., son of the Rev. A. Lea-Wilson, Vicar of Leavesden, and grandson of the late C. Lea-Wilson, Esq., of Beckenham, Kent, to Muriel, daughter of Mrs. Lutman, of Pinner Wood House, Pinner.
M'EWEN—CLARK.—On Oct. 2nd, at the Cathedral, Calcutta, Thomas M'Ewen, L.R.C.S.P.E., Joyhing, N. Lakhimpur, son of the late Thomas M'Ewen, Balderneck, to Luie Foster, daughter of the late J. T. Clark, Esq., of Ilderton, Alnwick, and Mrs. Clark, Moored, Newbiggin-by-Sea, and granddaughter of the late J. Scott, Esq., of Coneygarth.

Deaths.

- BETTS.—On Sept. 6th, suddenly, at a nursing home, Edward George Betts, M.R.C.S., of 37 Cavendish Square, W.
CROWLEY.—On Oct. 5th, at "Lyndhurst," Thames Ditton, Deputy-Surgeon General T. J. Crowley, R.N., eldest son of the late Dr. Crowley, Kilbrint, Co. Cork.
HOWIE.—On Oct. 3rd, at Beamsville, Ontario, after an operation, John Coulson Howie, M.A., M.D., eldest son of Rev. Robert Howie, D.D., of Glasgow.
LIGHT.—On Oct. 1st, at Cromer, of septic poisoning, Edwin Mellor Light, M.A., M.D., B.C.Camb., Chief Medical Officer of the Prudential Assurance Co., of 125 Ebury Street, Eaton Square, S.W., in his 52nd year.
PARSONS.—On Oct. 2nd, at Canon Pyon, Hereford, Louisa Anne, wife of H. Franklin Parsons, M.D., of Oakhyrst, Park Hill Rise, Croydon, aged 66.
WOAKES.—On Sept. 30th, at Belvoir, Fareham, Hants, Edward Woakes, M.D., late of Harley Street, aged 75 years.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX"

VOL. CXLV.

WEDNESDAY, OCTOBER 16, 1912.

No. 16.

NOTES AND COMMENTS.

The Reticence of "Truth." In a recent issue we commented upon the fact that *Truth* had spoken of THE MEDICAL PRESS AND CIRCULAR as one of the most narrow-minded of the medical journals. As there was not a word of support to this apostrophe, we pointed out that in form it savoured of the methods of simple abuse, and was unworthy of the methods instituted in that journal by the late Mr. Labouchere, who was always ready with chapter and verse, and with the methods of formal reasoning, to support views that, however extreme, were never obscure nor frankly abusive. To this challenge the erstwhile doughty *Truth* has answered never a word, but has published a whole page advertisement of Sandow, who professes to cure all sorts of diseases by a system of physical exercises, and publishes a book dealing with diseases of the nervous, circulatory and all other ills to which flesh is heir, including the special ailments of women! With such an advertisement in its pages it is hardly surprising that *Truth* should regard orthodox medical men and their internal disciplinary methods as a mere superfluity of airs and graces when they can go to such heaven-gifted geniuses as Sandow and Barker, who between them apparently can cure any human malady, and, incidentally, put a mint of money into editorial coffers. There is nothing illegal in the transaction, and it may be due to sheer narrow-mindedness if we insist that members of our own profession should not be allied with the two medically uneducated individuals in question. At any rate, we have the General Medical Council and the Privy Council at our back.

The Advantages of Isolation. It is, of course, evident to all that there are material advantages attached to the position of those medical men who do not join with the overwhelming majority of their professional brethren in refusing to serve under the National Insurance Act in its present form. Indeed, the campaign may be said to have assumed a determined policy from the day of the "great betrayal" of the British Medical Association by one of its prominent officials. At the end of September it was announced by a London newspaper—the *Daily Express*—that of the four medical men in Scotland known at that time to have agreed to work under the Act, two of them, to wit, Dr. Knight and Dr. Cullen, had received "excellent appointments." A curious fact commented on by the same journal is that "The National Insurance Medical Association," of which Charles Frederick Knight, M.D., is the Organising Secretary, has advertised for 1,000 motor cars, for what precise purpose is not known. A newspaper interviewer failed to extract any more detailed information

from Dr. Knight, although with practical common-sense he fixed on the economics of the situation. The thousand cars, even at the low price of £250 apiece, work out at a quarter of a million of money. Dr. Knight is said to have replied that a number of wealthy persons were interested in the Association and the money would be forthcoming. Here the story ends and the motor-car scheme remains "wrop up in mystery." If funds are forthcoming in this lavish way for those who elect to join the opposition it may well cause the weak-kneed among our ranks to waver. Fat posts, motor-cars, and the prospective favours of a grateful administration may well give pause to a practitioner struggling to make both ends meet.

Hospitals and the Insurance Act. THE important matter of the relation of the voluntary medical charities to the Insurance Act has been, to a great extent, overshadowed by the wider question of the administration of medical benefits. Assuming that the co-operation of the medical profession is once secured in that direction, the hospital problem will at once demand careful attention. Members of the honorary staff of those institutions who have hitherto given their services gratuitously to the hospital patients cannot be expected to do so any longer under the altered conditions introduced by the Act. If the rest of the medical profession is to be paid by the State for attendance on insured persons, there can be no logical reason for the non-payment of medical men because they happen to be treating the same class of patients within the four walls of a hospital. It seems tolerably certain that the crowded out-patient rooms of the medical charities will be, to a great extent, depleted when the Act comes into operation, and such a result is likely to be an un-mixed blessing to the honorary staff as well as to the patients. The out-patient department will then, in all probability, drift more and more into the position of a consultative organisation. In that case what will happen to the members of the medical staff who are clearly entitled to a readjustment of the terms of their appointment in view of the State aid granted to the large section of the public from whom hospital patients are drawn?

The Position of the Honorary Staff. So far as one can judge, hospital surgeons, physicians and specialists will always be required, and if their services are necessary to the State they will have to be paid at the higher rates of remuneration appropriate to their specialised skill and their long and costly training. Some day it seems not unlikely that the whole of the hospital service of the country may come under the control of the State, and we trust the opportunity of holding paid appointments under

that system will be more widely available to medical men than it is under existing conditions. One conviction seems to be steadily gaining ground, namely, that the Insurance Act has sounded the knell of gratuitous hospital work. The economic principle underlying the running of medical charities by the unpaid services of medical men has always seemed to us unsound. In many cases it inflicts great hardships upon young men who aspire to a place in the higher ranks of the profession. During the discussions that have waged of late round the Insurance Act it has been often urged that it is to the benefit of the community to have a prosperous and well-paid class of medical practitioners to attend the class of insured persons. Surely it is of no less importance to the community to have an ample supply of consultants and specialists sufficiently well off to carry on their progressive work with the requisite amount of vigour and thoroughness. It is to be hoped that every member of the honorary staff of the medical charities in the United Kingdom will find himself, in future, remunerated for services that are indispensable to society.

The Ruling Passion. It is a well-known psychological fact that stimuli, applied when the ordinary waking consciousness is in a state of abeyance, may be followed reflexly by a speedy response, usually of the motor type. Such resultant action, though accompanied by all the signs of active life, is frequently independent of consciousness, or, in other words, the so-called subliminal state is entirely responsible for all the phenomena evoked. It is this sub-conscious personality which may, under certain conditions, be influenced powerfully by external influences, when any suggestions then received may be acted upon in the ordinary waking state. There have not been wanting instances in which some dominant passion or emotion has manifested itself even upon a death-bed in the performance of some accustomed act, or the rehearsal of some imaginary scene familiar to the dying person. It is said of Mr. S. Coleridge-Taylor, the composer, who died the other day of pneumonia, that shortly before his death, while still unconscious, he sat up in bed and conducted perfectly the whole of a new work as if before an orchestra, with great vigour, which strange procedure lasted for twenty-five minutes. Even *in articulo mortis* we see the triumph of mind over matter, and the equality, or even superiority, of the subliminal as compared with the everyday consciousness.

LEADING ARTICLES.

PUBLIC HEALTH IN CANADA.

ELSEWHERE in our columns will be found an account of the recent meeting of the Canadian Public Health Association in Toronto. There is a peculiar interest attached to the Dominion at the present time, for it has become the centre of attraction for a large and increasing number of immigrants from the United Kingdom as well as from other countries. The sudden increase of population thus entailed has naturally added not a little to the anxieties of those responsible for the public health administration of a vast territory which, in its existing stage of development, presents the problems inseparable from the conditions of a comparatively young community. One of the difficulties is the prevalence

of enteric fever owing to the pollution of water supplies. In the course of time this particular disease will no doubt gradually disappear, but in this connection it may be well to remember that even in the United Kingdom enteric fever is still one of the fatal zymotics, although for many years past it has been steadily diminishing. It is to be hoped that with the rapid growth of big cities by the sides of her magnificent lakes, Canada will not be foolish enough to follow the example of American cities, built under similar circumstances, which discharge their sewage into the very lakes from which they draw their drinking water supplies, and are decimated with enteric fever. In Canada that essentially filth disease flourishes both in town and country, and in the latter it adds not a little to the anxieties of those in authority. For in spite of its continental dimensions the problems of crowded town life to be met with therein are no less acute than those of the great cities of Europe. The direct cause of this undesirable development is the large influx of European emigrants from various countries, but chiefly from those of the South and from Italy. With regard to the latter it is notorious that they come from countries whose standards of sanitation, both public and private, are in a lamentably backward condition. There is some reason to hope, however, that they will sooner or later share the general interest in health matters evidenced by the large attendance of all classes of society at the recent meetings of the association. One of the most significant features of that gathering was the great interest shown in the influence of industrialism upon the general welfare of the community. The matter was dealt with in an able paper by Dr. P. H. Bryce, Superintendent of Immigration, under the title, "Shall Canada Save Her People from the Physical and Mental Degeneration Due to Industrialism?" The Dominion is undergoing so rapid an expansion that the subject must inevitably become one of daily increasing importance. It is complicated by a great variety of considerations. For instance, the cost of living is a point that closely affects the well-being of the working classes as a whole. In Canada Dr. Bryce showed that the increased cost of living was 27 per cent., in the United States 29 per cent., in Germany 40 per cent., and in Great Britain 5 per cent. for the year. He asked how long a country, essentially a producer of raw materials by virtue of geographical location and extent of territory still largely undeveloped, could continue normally to develop and prosper when it has shown a displacement of rural population during the past ten years never witnessed before in the history of any people, and an increase of urban population rapid even beyond the palmy days of United States immigration. The conditions thus described must exercise a profound influence upon the economic future of Canada, and upon the maintenance of a sound national physique, which must sooner or later determine the survival or otherwise

of every nation in the great struggle for existence which is part and parcel of the conditions imposed upon the highest phases of life upon the earth. In more than one respect Canada has an advantage over the mother country, which has been forced by dint of many centuries of hard experience to work out her own salvation in sanitary matters. The Dominion steps into a splendid scientific heritage, and can appeal to the accumulated knowledge of the Old World for guidance in many a tangled problem. Then, again, the Canadians are gifted with the ardour and high ideals inseparable from a community which is awakening to a sense of its vast potentialities. Lastly, one of the most gratifying features of the situation is the general response shown by Canadians of all sorts and conditions to the invitation to interest themselves in matters of public health. The old saying that legislation can never advance far beyond popular enlightenment applies with special force to a country distinguished by the sturdy independence of her citizens. In this respect it may be said that Canada is fully abreast of the United Kingdom, where only of late years has an intelligent and active interest been shown by the proletariat in practical matters affecting the public health.

THE DAILY NEWS AGAIN.

ON various occasions since the passing of the Insurance Act we have had occasion to comment upon the hostile tone adopted by the *Daily News* with regard to the medical profession. The journal in question is commonly believed to be a sort of semi-official organ of the Liberal government, and, therefore, to be more or less behind the scenes. If its general rancour against medical men is even a faint reflection of the official attitude it would afford a key to much recent history. In its issue of the 14th instant, it has a leaderette devoted to the triumph of the Insurance Act, which winds up by a comment upon the one serious difficulty yet to be solved. "The present position," it says, "with regard to the doctors is one with which we ought not to be faced at this late stage." That is the point we have been urging for the past eighteen months. Mr. Lloyd George should have begun with the doctors, instead of at first ignoring them, then dealing with a handful of nominal leaders, and finally putting off settlement until the eleventh hour. If the *Daily News* has a bone to pick with anyone it should be with the Chancellor of the Exchequer and not with a flouted profession. The original scheme, wails the *Daily News*, would put a million of money into the pockets of medical men, but it does not add how much it would have extracted by diverting many millions of private into contract patients. The increase to 7s. 6d., it moans, would mean a million more. Then with gathering force the editor exclaims, "The nation will not tolerate this policy of blackmail." It is a pity that the law of libel does not cover a dastardly

insult of this kind levelled at a noble profession, which is poor in pocket as it is high in ideals. "The State has placed the doctors in a privileged position," remarks this indignant Solon, "but they must not be permitted to use that privilege in order to exact grossly unjust terms which will have to come out of the pockets of the people." It is news to us that the man in the street carries terms in his pockets, but apart from the mere hysterics of a political editor who feels that the ground is being cut away from under his feet we fancy there must be more strictly personal incentives at work to explain this sustained bitterness of the *Daily News* against the medical profession. Can it be that he prefers the medical services of unqualified persons who advertise at length in his columns. If a title of the claims, say, of Sandow and of Macaura could be believed, what need is there of State-qualified medical practitioners? There is just this little difference between the qualified and the unqualified. The *Daily News* grudges the sum of seven shillings and sixpence to a qualified medical man for attending an insured person at all times and all seasons, and for devoting to him the full measure of a long and costly education and experience. The unqualified Sandows and Macaurs have no need of half-crowns from the State, they play for higher game and succeed so well that they are able to spend scores of thousands of pounds in mere advertisement. What has the *Daily News* to say to this aspect of the matter? Possibly that journal, in the manner familiar to that baser journalism which lives in an odour of sham philanthropy, will decline to defend where it has not hesitated to assail. We wonder how many lives have been ruined and destroyed by the agency of questionable advertisements published in the columns of this self-appointed censor of the medical profession?

CURRENT TOPICS.

The Health of Tinsplate Workers.

ACCORDING to the report recently issued by the Medical Inspector of Factories on the conditions of employment in the manufacture of tinsplate, the mortality of the workers in the trade as a whole, between the ages of 35 and 45, is below the standard for occupied and retired males, but at every other age it is excessive, being 4 per cent. above the average. The principal diseases from which these operatives suffer are cancer, phthisis, and diseases of the nervous, respiratory and urinary systems. The work itself exposes those who labour to dust and to fumes. Rheumatic affections appear to be prevalent among many of the tin-house workers. The report, which is made by Dr. Collis and Mr. Hilditch, refers to the lamentable recklessness which is too often displayed in replacing fencing of machinery that has been temporarily removed, which is still responsible for a considerable number of accidents. The inspectors are of opinion that the precautions necessary for the safety and health of the operatives, might with advantage be discussed in a conference with the employers and workmen. This should lead to a higher standard, especially in new installations; but certain requirements, they say, should be made

binding by regulations. These regulations provide, amongst other things, that tinning shall not be done except in connection with an efficient exhaust draught; cleaning and dusting shall not be done except under such conditions as to prevent, as far as possible, the escape of dust into the air of any place where work is carried on.

Care of the Feeble-Minded.

WHEN we compare the conditions under which our labouring classes live and from which only the most robust rise, with some of the elaborate and expensive retreats provided for the insane, we feel inclined to become despondent. The unfit are fed and clothed, in practical comfort, while the poor and physically strong sink into the mire. Such a view would, however, be founded on a very superficial aspect of the situation. The primary reason for well equipped asylums is simple humanity, but no less important is the secondary reason, for scientific care of the feeble-minded, and particularly investigation of the causes at work in the production of insanity. Without the study of disease we cannot grapple with its cause, nor bring about its cure. We must acknowledge that our methods in this country are directed principally to keeping insane patients comfortable, and that there is a large mass of material on which accurate scientific work might be based, but which lies unstudied in our workhouses and asylums all over the country. We might follow with advantage the example of America and establish psychopathic hospitals, of which the main object is the observation of early cases of insanity. That established in Massachusetts, under Dr. Southard, promises to do work on lines which have not been followed hitherto. This hospital has only been in operation for about three months, but already numerous patients submit themselves to observation, and so make it possible to treat mental disease early. There is also a system which ought to be more widely adopted of tracing backwards the family histories of patients in order to arrive at some cause or premonitory symptom of mental aberration.

The Value of "Freibanks" in Populous Centres.

EVERY medical officer of health and sanitary inspector is aware of the waste of good, edible meat that sometimes occurs when the carcasses of animals affected with localised forms of tuberculosis are destroyed. An interesting and instructive paper was read by Mr. Daniel Hamilton, F.R.C.V.S., at the recent congress of the Incorporated Sanitary Association of Scotland at Montrose, on the advisability of establishing "Freibanks" in populous centres. The "freibank" (*i.e.*, isolated shop) has been proved to be not only a food saver, but a popular institution, and it, or a similar centre, has been in existence in Germany since the thirteenth century, when the town of Augsburg issued regulations prescribing that no butcher who shall slaughter a measly animal shall sell the flesh of such animal to anyone without declaring its condition, and that such meat must not be sold at the ordinary meat booths, but at a separate one situated some distance from the other booths. The "freibank" is, therefore, only for the sale of the flesh of animals which is found to be of an inferior quality or affected with some disease, and is sold either raw or sterilised as the veterinary inspector might direct. The majority of the Continental countries have a universal standard for the inspection of meat, and stringent regulations are issued instructing the inspectors how to deal with

healthy or diseased meat under its many different forms and conditions. A "Freibank" is erected and conducted by the local authority. It is usually near, or situated within, the municipal slaughterhouse, and is under the direct control of the official veterinary surgeon, the work of dividing, weighing, and selling the meat being discharged by a member of the slaughter-house staff. Economic, as well as hygienic, considerations seem to point to the advisability of giving the system a trial in this country.

An Old Fee Book.

A RECENT number of *The New York Medical Journal* gives some interesting extracts from the Fee Book of an Irish physician of the seventeenth century. Two pounds—paid in advance—was the fee in a case of gonorrhœa. "For escaping a putrid sore throat," one Meroney was mulcted in eight shillings. With pardonable pride Dr. Thomas Arthur relates how a *post mortem* examination proved his diagnosis accurate in the case of a woman fifty years old, and nineteen married, whom his "seniors in medicine" killed with hydragogues for an alleged ascites in the eighth month of her pregnancy. "For this I obtained," says he, "not a little praise." The nomenclature is sometimes a little puzzling—blindness due to suffusion, torrid bile causing a stomachic cardialgia, an hysterical hydrops, a scirrhus of the liver from metastasis of the monthlies, and a fisherman, caught by an anchor, were all cases treated by him, for the most part with success. His annual income fluctuated about the region of £70 till 1627, when he reached £105, after attending and curing Archbishop Ussher. He did better from this on, and in 1632 nearly reached £300. Altogether, when fully established, he must have earned an income worth, in spending power, about £1,000 a year at the present day. On the whole, conditions approximated fairly closely to those of country practices of the present day. The worthy doctor had a distinct scale of fees, according to the standing of the patient, and the time and trouble he had to give to the case.

Therapeutic Advance.

EVERY day the physician's attention is systematically and insistently called to the advantages of some or other new pharmacological product. He is overwhelmed by advertisements of synthetic and extractive preparations that herald with polysyllabic vagueness the final victory over all or some of the ills that are our heritage. There are many skilled and earnest workers in laboratories who give their best to the construction and examination of new remedies. Their tests are very thorough, and physical and physiological properties are worked out to something approaching finality. In fact, every side but the clinical receives the chemist's best attention, and while the effects of divers drugs are beautifully illustrated by diagrams showing all the results of intravenous injection, we may be led into analogies that are entirely false, since in practice there are very few remedies that are so given; the effects when given by the mouth may not be what we expect. For example, digitalis, which causes a rise in blood pressure when given intravenously to an animal, has recently been proved to have no such effect when administered by mouth to man. Adrenal extracts by the mouth leave blood pressure unchanged, but intramuscularly cause a marked rise in the human subject. A clinical scheme of observation would be invaluable. Of course, such a scheme would be much slower in its results than the present laboratory methods, and would need men who could impersonally subtract extraneous matter from their results and give

the drug no more and no less credit than its due. The facts, when collected in sufficient numbers at the bedside and collated, would give us a much firmer therapeutic base to work on than we have at present. The effects of some few drugs—*e.g.*, digitalis—could be examined almost without apparatus by any practitioner, but most will require long and careful observation in hospital wards, where the utmost accuracy in examination and record will give us conclusions on which we need never hesitate to act and which would clear up the tangle of ephemeral panaceas through which we are now trying to struggle.

The Irish Local Government Board and Domiciliary Treatment.

An important question has arisen in Dublin as to the powers of insurance committees in administering the sanatorium benefit. For the past few months the Dublin County Borough Insurance Committee has been in the habit in the case of patients undergoing domiciliary treatment, of making arrangements for the supply, where necessary, of additional food, clothing, bedding, and accommodation. All treatment provided under the sanatorium benefit must be approved by the Local Government Board, and must be to the satisfaction of the Insurance Commissioners. The Commissioners expressed some doubt as to the wisdom of the course adopted by the Insurance Committee, but avoided giving a definite decision. The Local Government Board, however, after a long delay, communicated to the Insurance Committee their decision that the treatment in question did not come within Section 16 (i.) (b) of the National Insurance Act. A deputation from the Committee waited upon the Board last week, and urged very strongly that the attempt to treat patients for tuberculosis without the power to supply food and clothing, where necessary, would be futile. A prolonged discussion took place, and the Board promised to reconsider the matter. We hope that as much discretion as possible will be left to individual committees, and that they may not be hampered by an unduly restricted outlook, in the administration of the benefit. It is probable that the Local Government Boards of the three countries will act in unison, and it is, therefore, important that professional opinion should make itself felt.

PERSONAL.

DR. A. E. CARVER, M.B., B.C. Cantab., has been appointed Tuberculosis Officer to the Birmingham General Dispensary.

DR. FREDERIC C. DODSWORTH is about to retire from the post of Medical Officer of Health of Chiswick, which he has held since 1878.

MR. R. C. ELMSLIE, F.R.C.S., has been appointed Surgeon in Charge of the Orthopædic Department at St. Bartholomew's Hospital.

DR. HUGH WALSHAM, M.D., F.R.C.P., has been appointed Medical Officer in Charge of the X-ray Department at St. Bartholomew's Hospital.

DR. H. A. POWELL has been appointed a member of the Consultative Committee of the Board of Education by the President thereof for a term of six years from October 1, 1912.

DR. HENRY MACCORMAC, M.B. Edin., M.R.C.P., has been appointed to the newly created office of Assistant Physician to the Department for Diseases of the Skin at the Middlesex Hospital.

DR. E. P. CUMBERBATCH, M.A., M.B., B.Ch., M.R.C.P., has been appointed Medical Officer in Charge of the Electrical Department at St. Bartholomew's Hospital.

AMONG the women candidates for the forthcoming Metropolitan Borough Council elections are the names of Dr. Ethel Bentham (Lab.), Kensington, and Dr. A. Leline Roberts (M.), St. Marylebone.

DR. ARCHIBALD DONALD, M.D., M.R.C.S., has been appointed to the Chair in Obstetrics and Gynæcology in the University of Manchester, vacant through the death of Professor Sir William Sinclair.

DR. C. W. SALEEBY, F.R.S.E., delivered an interesting address on "Alcohol and the Insurance of the Race," at the opening of the Western Temperance League Conference at Bristol last week.

SIR THOS. B. CROSBY, M.D., Lord Mayor of London, will give a dinner at the Mansion House on Friday, November 14, to meet the Presidents of the Royal Colleges of Physicians and Surgeons.

A PORTRAIT of Sir Henry Holland, Bart., M.D., F.R.S. (1788-1873), by Thomas Brigstocke, is among those recently acquired by the Trustees of the National Portrait Gallery, where it is now on exhibition.

DR. STENHOUSE WILLIAMS has been recommended by the Health Committee of the Liverpool City Council for the appointment of Deputy City Bacteriologist and Analyst under the Sale of Food and Drugs Act.

SIR WILLIAM LEISHMAN, F.R.S., will introduce a discussion on the aetiology of blackwater fever at the first meeting of the Society of Tropical Medicine and Hygiene, to be held on Friday next, at 8.30.

MR. G. has been appointed Assistant Surgeon to the Children's Department at the Ulster Hospital for Children and Women, and Assistant to the Professor of Surgery at the Queen's University, Belfast.

DR. ALEXIS CURREL, of the Rockefeller Institute of New York, has been awarded the Nobel Prize for Medicine for 1912 for his work on the suture of vessels and the transplantation of organs. The value of the prize this year amounts to about £7,800.

PROFESSOR LORRAIN SMITH, the newly appointed Professor of Pathology in Edinburgh University, delivered his inaugural address on Wednesday before a large gathering, choosing for his text "The Essential Unity of Pathology and Medicine." Our Edinburgh correspondent gives a *résumé* of the address in another column.

IN recognition of his long and valuable public and professional services in Chirside during 36 years, Dr. McVie has been the recipient of a silver loving-cup and a purse of 160 guineas. The testimonial was raised by his patients and friends, and the presentation was made on their behalf by Mr. John Gillies, Edington Mill, on the 11th inst.

PROFESSOR DR. NIETNER, of Berlin, General Secretary of the German Central Committee for the Prevention of Tuberculosis, will deliver the inaugural lecture at the Medical School of the Royal Hospital for Diseases of the Chest, City Road, E.C., on Thursday, October 17th, at 5 p.m., on "The Modern Combat against Tuberculosis amongst Children." The chair will be taken by Sir William Osler, Bart., F.R.S.

A CLINICAL LECTURE

ON

PLASTER OF PARIS IN SURGERY. (a)

By WALTER C. S. STEVENSON, M.D., B.Ch., D.P.H.,

Surgeon, Dr. Stevens' Hospital; Surgeon Incorporated Orthopaedic Hospital, Dublin.

GENTLEMEN,—As plaster of Paris is so constantly employed in orthopaedic surgery, and in surgery of the bones in general, I think it may be of service if I indicate some points to guide you in its uses and methods of application. We commonly apply it in the shape of plaster of Paris bandages. These may be purchased at prices varying from 5d. to 10d. each, but it is most satisfactory, certainly in hospital practice, to have them freshly made in hospital.

TO MAKE PLASTER OF PARIS BANDAGES.

The best bandage material to retain the plaster is crinoline, also called in the trade "checked muslin." It costs about 4½d. a yard (30 ins. wide), and is sold by the piece. The crinoline is boiled two or three times, to get rid of the starch, and then drawn to stretch it. The selvage is removed, and the piece is cut into strips from 1½ ins. to 5 ins. wide, and five or six yards long, according to the requirements of the case. Thus the wider bandage, 5 ins. wide, is best for an adult's spinal jacket, while a narrow one is more serviceable for an infant's foot.

In making the bandages, only the best white dental plaster should be used. It should be quite

shillings.

The plaster bandages are made on a table. The crinoline is rolled up loosely, and about a foot of the free end placed on a bed of plaster. Some more is spread over it, and rubbed in well with the hand, so that plaster is caught in the meshes of the muslin on both sides. As the first foot length is done it is rolled up loosely, and the next foot treated, till the whole bandage is completed and rolled.

The storing of plaster bandages is most important. They should be put, with the loose plaster, in air-tight boxes, and kept in the stove room or kitchen. In damp weather they should be placed in the oven the night before use. The oven must not be so hot as to scorch the fabric, thereby destroying the bandage.

APPLICATION OF PLASTER BANDAGES.

In applying plaster, it is usually put on over a flannel bandage. A couple of years ago, Mr. Swan introduced here the use of unprepared cotton wool, which is brownish in colour. It is rolled into bandages and sterilised. This wool is much cheaper than bandaging, is pleasant against the patient's skin, and protects it from undue pressure and irregularities of the plaster. The limb is completely enveloped in the wool, particular care being taken that bony points are well padded.

The limb having been covered, and everything being in readiness, the plaster bandage is removed from the plaster box, and put, standing on its end, in a bucket of water, so that it is completely covered. As the bandage is loosely wound, the whole plaster gets thoroughly wetted in a couple

of minutes, and is ready for application, as soon as the bubbling ceases. It is removed from the bucket and squeezed to get rid of the excess of water. If working single-handed, it is well to put in a second bandage, when the first is taken out of the water, so that it may be ready when the first has been applied, and so on. The bandage should be wound on to the limb rapidly, evenly, and fairly tightly, and should be well rubbed with the fingers to make the layers blend together. On this vigorous rubbing depends the durability of the plaster case. Every part should be covered by two layers at least, and the part subject to the greatest strain should have most plaster.

If the bandage is not wet enough at any part more water should be poured on with the hand, until the plaster is rubbed smooth.

The plaster case may be reinforced by incorporating oak chips or soft iron bands. One requires to be careful that the reinforcing material does not press the plaster unduly on the tissues. A little padding under the ends will prevent this. Finally, the plaster case is smoothed off with a handful of plaster, which has been dipped in water. It adds greatly to the safety and comfort of the case if, as soon as it is partly set, which good plaster ought to be in four to six minutes, it is cut down with a sharp knife, through its whole length and thickness. It is an advantage, and safer for the patient, to cut slantwise, so as to have a bevelled edge. The case will spring a little, but the broad edges can be easily kept in apposition by a muslin bandage. This also saves much time when the plaster requires removal. Otherwise the removal may be a tedious procedure. A weak solution of acetic acid, dabbed along the line to be cut, makes the work easier. Another method is to apply the plaster over a couple of strands of pianoforte wire. The wire is used as a saw when the plaster is to be taken off. If one is constantly putting on plaster, it is well to wear rubber gloves to save the hands, or at least to vaselin the hands and nails well.

A plaster case, if the plaster is good, will set firmly in five minutes, and be fairly dry in a couple of hours. It is not, however, thoroughly dry for a day. If it has to be worn for a considerable time it should be sized or painted when dry. A fairly strong watery solution of silicate of soda or water glass, commonly used for preserving eggs, if painted on, will give the case a glossy appearance, make it fairly waterproof, keep it from chipping, and prevent the plaster rubbing off on to the clothes.

I propose now to deal briefly with the uses of plaster of Paris in certain surgical conditions.

Fractures.—The routine use of primary plaster treatment for fractures of the limbs is on the whole most satisfactory. By the use of judicious cotton wool padding, and the practice of cutting down the plaster case when set, the danger of swelling strangulating the blood supply is almost negligible. In fact, the plaster case will to a large extent prevent the swelling, or if swelling has already formed will tend to reduce it, owing to the elastic recoil of the cotton wool. The case fits accurately, keeps the

(a) Delivered at the Orthopaedic Hospital to the Post-Graduate Class, Royal College of Surgeons, Ireland, October 10th, 1912.

limb quiet, and alleviates the patient's sufferings. Skiagrams of the limb should be taken as soon as possible through the plaster to verify the position of the parts. If this is not satisfactory the displacement can be corrected in accordance with the exact knowledge obtained by the skiagrams, and fresh plaster applied, with the patient under an anæsthetic if necessary. The plaster case can at any time be removed temporarily for massage and mobilisation of the limb.

Occasionally it is expedient in fractures of the leg to hasten the process of repair by letting the patient walk. I remember one case where X-rays showed no bony callus ten weeks after the accident, though the fragments had been wired. I incorporated a slipper and stocking in the plaster case, and allowed the patient to walk about on the injured limb with the aid of a stick. Most of the body weight was transmitted from the ground through the plaster to the tubercles of the tibia, which were tightly grasped by the case.

Dislocations.—Though plaster is usually not necessary in traumatic dislocations unless bone is involved, as in the case of a fractured coronoid in dislocation of the elbow, yet it is sometimes useful in subluxations. I cured one case of long standing traumatic displacement backwards of the head of the ulna (due to torn and stretched ligaments) by a plaster case worn for three months.

In Operations.—Plaster of Paris is in constant requisition in the operating theatre. A light application of plaster is a nice method of fixing the limbs and the dressing after an extensive removal of varicose veins. It is essential to maintain the correct position after osteotomies for rickety curvatures, etc., in orthopædic work. As we utilise a tourniquet in bone operations bleeding must be carefully guarded against. The operation wound is well padded. Pressure applied over this dressing makes a depression in the plaster case, which by keeping up the pressure effectually prevents hæmorrhage when the tourniquet is removed. After plating or wiring fractured bone, it is usually necessary to leave in a drain, and to cut a window in the plaster case. The plaster and wool frequently get soaked with blood. If, at the first dressing, the parts are dusted with boric powder, and the plaster and wool copiously sprinkled with saturated alcoholic solution of mercuric biniiodide, the case will remain sweet and clean, and as no decomposition will occur, the parts need not be further disturbed. The same remarks apply to sequestrotomies, where some hæmorrhage cannot be avoided. In these cases plaster is often necessary to correct the position of the neighbouring joints and to prevent fracture of the weakened involucrum. In excision and operations on joints plaster makes the most convenient and comfortable splint.

Spinal Caries.—Plaster is used to fix the patient to a Whitman's spinal splint or to make a spinal jacket. For instance, we wish to apply a jacket to a marked angle in the lower limb. The roller towelling is suspended at three feet from the ground above a table (Swan's method) and the patient lies face downwards stretched above the head. A small pad ("dinner pad") is subsequently removed. The plaster is applied along the sides of the patient's trunk. Bandages are wound round the chest, back, neck, and scapulae, or a tight vest, between the legs, may be used. The padding is well padded. If the angle is marked, it should be padded round till the flat

of the hand pressed against it feels no prominence. The case cannot then injure the skin as it is otherwise likely to do. An assistant steadies the hips while the bandage is applied from below upwards. The first layers should be as tight as possible, but the outer ones may be looser. If this rule is not observed, the layers next the skin will become wrinkled, and the case most uncomfortable or impossible to wear. I should again emphasise the importance of thoroughly rubbing the bandages to blend the layers together. If the costo-vertebral joints are affected, it is well to splint the ribs by moulding the case against them with the finger. The jacket is also moulded over the iliac crests. The patient is then let down on to the table, above which he has been horizontally suspended. The towelling is cut away above and below the plaster, the intermediate portion being left *in situ*. The patient is wrapped in a blanket, and after a few minutes laid down in front of a fire for a couple of hours. If the case is to be a removable one, it is cut down the middle in front before it completely sets. It is sent to the instrument maker to be bound with leather, and have eyelet holes or hooks put on for lacing down the front.

Scoliosis.—The jacket is put on while the patient is in self-extension, that is, suspended by straps under the chin and occiput. The curves unfold to some extent in this way and the jacket maintains the improved position. A more complicated correcting jacket is made by padding the patient's chest with wool till the figure appears symmetrical. The plaster case is then applied with self-extension. Windows are cut in the jacket opposite the prominent ribs behind and the retreating bust in front. The deformity is corrected by transferring from time to time a little padding from the front to the back of the chest, so that pressure is exercised on the prominence, while the depressed side has room to expand.

Hips and Thighs.—For applying plaster in this region, it is convenient to use Lorenz' stand or some modification of it. The patient is supported on a box at the head and shoulders, and a spear-head-shaped sacral prop, and his perinæum is pressed against a pillar which stands vertically at the base of the spear head. After reduction by Lorenz' bloodless operation for congenital dislocation of the hip the plaster envelops the pelvis and the trunk to the ensiform cartilage, and the thigh or thighs in a double dislocation, as far as the knees. The thigh is abducted to the frontal plane and flexed at right angles to the side of the body. The plaster is well moulded behind the great trochanters, over the iliac crests and symphysis pubis to retain the head of the femur in its reduced position. The patient is removed from the stand by cutting down on the vertical pillar and slipping out the spear-head. The plaster is trimmed round the perinæum. In Kocher's breeches for fracture of the shaft of the femur the plaster grasps the hip and pelvis above, and the irregularities of the knee, leg, and foot below, and, as extension is applied during the whole of its application, this is maintained when the plaster sets. For extension in *morbus coxæ*, plaster bandages are applied to the lower two-thirds of the thigh, leg, and foot, webbing, to which a stirrup is subsequently fixed, is incorporated in the plaster, so that the extending force of the weight over the pulley gets its purchase from the condyles of the femur. This arrangement has advantages over American strapping in that it does not irritate the skin, is better fixed, can be worn for a long time without being changed, and particularly does not stretch the ligaments of the knee-joint. A flail condition of that joint sometimes follows pro-

longed extension applied below the knee. Another advantage of the plaster of Paris extension is that eversion and inversion of the hip may be corrected by fixing the middle of a stick about eighteen inches long in the plaster. It is placed at right angles to the lower third of the leg against its posterior surface, so that when the stick is lying flat on the bed the eversion or inversion will be corrected. The correction can only be brought about gradually. In eversion of the right thigh, for instance, the end of the stick to the patient's left is raised, till the position is easy for the patient. From day to day this end is lowered until the limb can lie naturally flat on the bed.

Deformities of the Foot.—In children over three or four years of age with club foot, when the deformity is not improving satisfactorily by manual manipulations alone, the foot is wrenched with a Thomas's wrench till a valgus position is attained, and a plaster case is applied. The bandage is rolled round the foot in the direction from within outwards across the sole, so that each turn from the foot to the leg can be used as a stay to maintain the eversion of the foot. The plaster extends from the tips of the toes to below the knee. It is not necessary completely to enclose the heel. While the plaster case is setting, one hand steadies the ankle at right angles, while the other grasping the foot opposite the ball of the toes, everts and pronates it at the mid-tarsal joint, making the sole look outwards. After a week, when the soreness has disappeared, the plaster is removed and the foot again manipulated daily, and retained in a Scarpa's shoe or a night shoe.

In flat foot, after tenotomy of the peronei and wrenching, the plaster bandage is applied in the opposite direction to that used in the talipes varus. The foot is put up in an exaggerated varus position, with the sole well supinated, and the toes pointing up towards the opposite hip. The plaster is worn for six weeks, and then removed for exercise and massage of the foot, and the use of a valgus boot with an outside steel and an inside malleolar strap.

There is one point that is worth particularly noting when treating feet. The toes are very apt to be cramped together, a position very irksome to the patient and bad for the foot. This can be avoided by stuffing wool between the toes, which may be removed when the plaster has set. The toes are thus spread out, as they should be, and at the same time the plaster has good purchase on the metatarsal bones.

Plaster Casts.—Plaster of Paris is used for making casts, either as a record of a case, or for the guidance of the instrument-maker. The part to be dealt with, say a foot, is shaved and lubricated with sweet oil, so that the plaster will not stick to it. A suitable cardboard box or tray of some kind, in which the cast is to be made, is in readiness. Dry plaster is slowly stirred into a bowl of water until a fairly thick cream is formed. This is poured into the cardboard box, into which one foot is laid, only so much of the limb being embedded as will permit of its removal without breaking the mould. The upper surface of the lower half of the mould is smoothed with a knife or spatula, and allowed to set. It is then brushed over with sweet oil. The upper half of the mould is similarly made. When the plaster has set, the negative cast is separated along the oiled surface, and the foot removed. The parts of the cast are fitted and tied together, and left to dry. To make the positive cast, the inside of the mould is oiled and filled with plaster, prepared as before. When dry, the irregularities of the positive cast are trimmed off with a knife.

In conclusion, I shall summarise the advantages of the routine use of plaster of Paris. It is cheap,

can be easily stored and kept in readiness for immediate requirements. It does away with the necessity of retaining in stock a number of splints of various sizes, shapes, and materials, and with the annoyance of finding, in an emergency, that the particular splint or apparatus is not to hand. A plaster splint can be made to fit accurately, to protect the injured part completely, and to alleviate the patient's suffering. It can be moulded to correct a deformity and to retain the part in a correct position. It can be applied to exert pressure, to control hæmorrhage, to diminish œdema. By cutting windows in the plaster case, it can be used to ensure continued immobility where operation wounds and sinuses are present, or for the graduated rectification of deformities. It is fairly pervious to X-rays, so that the position of the bony parts can be ascertained without disturbing them.

Plaster of Paris allows the surgeon to be more or less independent of the instrument maker, who, at the best, obtains his knowledge of the requirements of the case secondhand. Besides, it is not convenient or time saving to have an apparatus made which may be only required for a week or a fortnight, especially if it has then to be superseded by another. It is true that plaster is rather heavy, but with experience in its application the number of bandages can be diminished. It does not necessitate an elaborate technique or expensive reinforcing materials, as do celluloid, leather, and poroplastic. Nor is it inflammable or easily injured. Finally, plaster of Paris is an old friend of the medical profession, and, I think, it will be difficult altogether to supplant its general utility by any substance that is at present known to us.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by T. G. Moorhead, F.R.C.P.I., Visiting Physician to the Royal City of Dublin Hospital. Subject: "Two Cases of Acromegaly."

ORIGINAL PAPERS.

SOME PRACTICAL POINTS IN THE TREATMENT OF ECZEMA. *Select*

BY G. S. STOPFORD-TAYLOR, M.D., M.R.C.S., &c.
Senior Physician at the Liverpool Skin Hospital.

GENTLEMEN,—I am sure that you will agree with me when I say that the most attractive branch of general medicine is that of the study of cutaneous disorders, and it has always been a source of regret to me that the General Medical Council has not made a higher standard of education obligatory in this most important subject.

Various reasons may be assigned for this apparent apathy.

Firstly, because common affections of the skin are rarely fatal, and secondly, because the student of to-day is already over-burdened with work.

Reform is necessary in medical education as in many other things, and, personally, I cannot see how this is to be effected unless the curriculum is extended. Fortunately, there are post-graduate classes in most centres of medical education for those who wish to learn, and general practitioners are always welcome at any clinic, but, unfortunately, these are of little value to those who live at a distance. Still, if men are desirous of learning, the difficulties of distance can be overcome. What is to prevent a country doctor from taking his annual holiday in a hospital city, such as London, Liverpool, Manchester, Birmingham, etc., and studying not only dermatology, but ophthalmology, gynaecology, and other branches of medicine?

Inaugural lecture delivered before the New London Dermatological Society, October 10th, 1912.

Reprinted from the Medical Press

We do not pretend to say that holiday studies will make a specialist of the general practitioner, but we can train him to use his powers of observation and other senses, and so avoid making glaring errors of diagnosis as in cases of itch and ringworm.

Which of us has not seen numerous cases of the former treated for "disorders of the blood," and the latter for dandruff?

A school attendance medical officer informed me that 95 per cent. of the certificates given by the general practitioner in a large city as to the fitness of children to return to school, from which they had been excluded because of ringworm, were incorrect.

If the general practitioner wishes to hold his own in the struggle for existence, he must, in the words of His Majesty the King, "Wake up."

I believe that the successful doctor of the future is the good all-round man. He must know how to use his microscope, ophthalmoscope, laryngoscope, otoscope, and other instruments of precision, and then he need have no fear of Mr. Lloyd George. Remember that pools in corn, cotton, iron and coal, and other products of the earth may be possible, but it is impossible to make a pool in brains, and by cultivating his brains the well-trained doctor will succeed.

Consider for a moment the advantage the British doctor has over his Colonial and American cousin, who leaves his country, say, every third or fourth year for the purpose of study in Europe. Does he lose anything by so doing? No; he gains, because his patients know where he has been, and conclude that he returns home brushed up and, consequently, a better doctor than he who has stayed at home.

Dermatology concerns the diseases which affect the largest organ of the body; an organ that stands in relationship to every organ within, and yet greater ignorance exists in the profession with regard to it than in any other department of medicine. It has been said, however, and with some degree of truth that the ignorance displayed by the general practitioner is on a level with the dermatologist's knowledge of medicine. How is dermatology taught in the majority of schools? As if the skin were a dead thing, affording a home for myriads of organisms to be destroyed by germ hunters with sulphur or other germicides.

I remember well a lady who had been so treated with sulphur that she was unable to sleep, and when she complained to the dermatologist who had prescribed for her, he replied that she was suffering from "nerve storms."

This brings me to the association of dermatology with general medicine.

No man should aim at being a specialist unless he has had a long and varied experience in general medicine. He should stand in relationship to the physician and surgeon as the royal marine, who is trained to fight on both sea and land, does to the sailor and soldier.

The definition and nomenclature of skin affections appears at first sight to be somewhat complicated, but it is really not so if common sense and patience be exercised. All that is required for the successful study of cutaneous maladies is, as in other branches of medicine, a practical knowledge of anatomy, physiology, and pathology. One great charm that the study of skin diseases possesses is, that the signs and symptoms are for the most part objective, and, consequently, their clinical course can be observed throughout.

Despite this, no two authors are agreed upon the definition of the commonest inflammation of the skin, viz., eczema; and it is a reflection upon the teaching of the day that such a disease should be undefinable.

Let us take the opinions of the late Radcliffe Crocker and of Malcolm Morris, which, on reference to their text books, are antagonistic.

Malcolm Morris says that "the artificial dermatitis excited by mechanical or physical agents is identical anatomically with the eczematous process, and gives rise to lesions indistinguishable from those of eczema," but I join issue with him here when he says, "but it is not eczema."

I would like to ask Morris the following questions:

First, did he ever see an outbreak of eczema of the face, forearms, and genitals suddenly occur whilst a patient was suffering from varicose eczema of the leg? Or did he ever see a dermatitis caused by a scald on the legs, an injury complicated by an outbreak of eczema, on parts far distant from the original injury? And such attacks proving most intractable to treatment, and in some cases, recurring at intervals for years, long after the injury had healed. I venture to say that such cases are to be found in London as they are in Liverpool, if only looked for. Are they not cause and effect?

Morris's position is this. Briefly, eczema, arising from an invisible cause, according to Morris, is the only true or *idiopathic* eczema. (The italics are my own.) Now traumata are a common cause of dermatitis admitted by him to be indistinguishable from eczema. Therefore, his argument, followed out to its logical conclusion, is untenable, because it may arise from a microscopical wound or one so small as to be overlooked.

Crocker's position, on the other hand, I regard as more easily maintained. He says, "I believe it is more logical and practical not to draw such arbitrary distinctions, and to consider all cases as eczema which correspond in their morphology and general behaviour irrespective of the cause being tangible or intangible, external or internal."

I have found the best working definition of eczema to be a catarrh of the skin which arises in response either to an external cause, or in consequence of some unknown or constitutional dyscrasia.

I am firmly convinced that a large proportion of cases of eczema originate from wounds, and in the past few months I have notes of typical outbreaks of eczema following a wound of the thumb due to a cut from a knife used for slicing tobacco; a burn on the wrist caused by some boiling fat, and an injury of the sole of the foot produced by a badly fitting shoe. In each of these cases the attack of eczema which followed was clinically indistinguishable from ordinary eczema, and I cannot see any reason, except a foolish desire to make confusion worse confounded, why these cases should be excluded from the category of eczema, and relegated into that of dermatitis. It is absurdities of this kind which bring dermatology into unmerited disrepute; and in our work as clinical teachers we should set our faces sternly against their further propagation.

From whatever cause arising, an eczema, once started, rapidly becomes septic, as the skin teems with microorganisms, and as soon as the protective layer of the epidermis is destroyed, or damaged and loosened by the inflammatory process, the products of sepsis are readily absorbed by the exposed corium, and we get outbreaks of eczema occurring at a distance from the original lesion.

In the *British Medical Journal* of September, 1897, I published a series of cases of skin eruptions of various types arising in patients already suffering from infected wounds. It has been one of my hobbies to collect the records of cases illustrating this point, and I should like briefly to quote a few of them here.

Case 1. A young lady, suffering from a moist occupation eczema of the hand, while under treatment suddenly developed an acute erythematous eczema of the face.

Case 2. A man applied several plasters to his left shin. Three days after the application of the second plaster there was an outbreak of typical eczema on the face and genitals.

Case 3. A woman sustained an injury on the back of the right arm. A fortnight before she came to hospital, the sore had dried up, and presented a scaly appearance. A doctor painted it with linimentum iodi under the impression that it was a ringworm. She was advised to repeat the application for three successive days. On attending at hospital the wound was found to be septic; the face was covered with an impetiginous eczema, and the shoulders, breasts, trunk, buttocks, and legs were covered with vesicopustules. There was a space over the dorsal vertebrae free from disease.

Case 4. A woman rubbed some liniment on her left arm for rheumatism. The liniment produced a blister. As this was healing there was a sudden outbreak of a symmetrical papular eruption along the front of both thighs and legs.

Case 5. A young woman, while suffering from an impetiginous eruption of the scalp, developed a papulo-vesicular eczema on the outer surface of both arms.

Case 6. A man, suffering from an eczematous eruption over the right knee joint, applied starch and boracic poultices at the suggestion of a friend. Unfortunately, he was not careful to cover the poultice completely with gutta percha tissue, so it became very dry and adhered to the skin. In forcibly removing it he did further damage to an already inflamed skin, and the following day he had a typical outbreak of papulo-vesicular eczema on the forearms, sides of neck and face.

Such cases might be multiplied indefinitely, and I am confident that if you will ransack your memories you will all be able to recall similar occurrences in your own practices. I do not know in what terms modern pathology would describe or explain these phenomena, but I am of opinion that our forefathers had more than an inkling of the truth, when they spoke of a humoral and neural pathology, and I consider that these cases can be explained by the assumption that we have to do with an absorption of morbid products into the blood or lymph stream, and the determination of an outbreak at some other part of the body through the influence of the nervous system. That the nervous system is a factor in the localisation of these secondary outbreaks is, I think, proved by the constancy with which the secondary eruption is symmetrical in distribution; and by the fact that clinical experience enables us to foretell the site at which these secondary rashes are likely to occur.

There is a certain attractiveness about these speculations, but I am essentially a practical man, and with your kind permission I propose to devote the remainder of this lecture to a consideration of some of the principles to be followed in the treatment of skin affections.

REST. One of the most instructive and inspiring books I ever read was Hilton on "Rest and Pain," and I would enter a most urgent plea for the observance of the elementary principle of rest for inflamed skins. For a generalised inflammation of the skin absolute rest in bed is a first essential for successful treatment. (But even when the inflammatory condition is a local one, rest for the inflamed part is a necessity.) Take, for example, an ordinary outbreak of eczema on such exposed parts of the body as the face, the hands, or other parts that have been exposed to the friction of clothing or other sources of irritation. The hands and face are continually being irritated by the atmosphere; the unrestrained play of the facial muscles keeps the skin of the face in a perpetual state of movement, while coarse and unsuitable clothing, in contact with an inflamed skin, gives it as little rest as a foreign body does to the ocular conjunctiva. Such eczemas will rapidly get well if the skin is protected from irritation by a suitable simple dressing. The movements of the skin of the face can be to some extent controlled, and its inflamed surface protected by means of a dressing and mask, the preparation of which I shall shortly describe to you.

I am a strong advocate for the dressing of skin affections by nurses specially trained in the work who carry out certain instructions. I am convinced that success in treatment is achieved by this means more rapidly than by the haphazard distribution to patients of pots of ointment or bottles of lotion, and in my clinic at the Liverpool Skin Hospital several hundred dressings are applied each week.

Let us take, for example, a case of acute moist eczema. In the first place, all morbid products are removed with boric, carbolic, bichloride, or cyllin lotions or baths, and this is followed up by the application of boric and starch poultices. These poultices, which consist of boric acid 1 part and starch 7 parts,

are used in all cases to remove crusts and clean up septic surfaces. They are clean, cool, and antiphlogistic applications, and are often beneficial when ointments are contra-indicated. To painful varicose ulcers they are very comforting, and often healing.

In dealing with most cases of acute eczema, a time comes when starch and boracic poultices must give way to other remedies. It is impossible to lay down any hard and fast rule for one's guidance as to when to make the change. This knowledge can only come from experience; but I think that these poultices may often be continued with advantage for a considerable period when they are used in conjunction with a dusting powder. The dusting powder I specially favour is dermatol, which, as you know, is the sub-gallate of bismuth. When dusted on a moist surface, all drying powders have the same defect, viz., they form crusts under which sero-pus accumulates. In order to obviate this, poultices are applied as well; and we get a combination of mutual advantages, the dermatol acting as a drying agent, the poultices preventing it adhering too intimately and damming up secretion; while the film of dermatol protects the skin from becoming too macerated by the poultices.

This method of combining a powder and poultice is an excellent manner of treating cocogenic folliculitis. When I judge that the time has come to change from poultices to ointments or pastes, the procedure is as follows. And here, I may say, that I consider as much depends upon the method in which the remedy is applied as upon the remedy itself; and the dressing I am about to describe has been gradually evolved after much practical experiment:—

A piece of ordinary lint, cut to the shape and size of the part to be dressed, is soaked in cold water, wrung out, still leaving a fair proportion of moisture, and laid flat upon a table. The ointment or paste to be used is then spread thinly and evenly with a spatula on the smooth side of the lint. As the lint is wet, it does not absorb much of the grease, and being wet it keeps cool and prevents the grease melting with the heat of the body, and finding the path of least resistance, viz., outwardly. Pastes and ointments after being spread, are always faced with butter-muslin, and this is of the greatest importance. I sometimes say to my students and colleagues that any fool can spread a paste on the skin, but it takes a wise man to remove it without damaging the delicate, newly-formed epidermis.

But the muslin face enables one to peel off the dressing like a banana-skin, and prevents too much of the paste adhering to the integument. Further, it facilitates surface drainage. In virtue of the water they contain, these dressings keep cool for several hours, and as the paste contains starch this tends to set in a slight degree, and thus the dressing acts as a splint, and helps to keep the inflamed part at rest. This form of dressing, while applicable to all parts of the body, is particularly useful when applied to the face, where it is kept in place by specially knitted nets.

The pastes which I find give the best results are, Lassar's paste, boracic paste, or a paste containing from 5-10 per cent. of sulphur.

Under such a dressing as I have described, a case of acute eczema progresses rapidly to a cure, and though the dressings are somewhat more expensive than simply giving a box of ointment to the patient for faulty application at home, the extra expense is well compensated for by seeing the satisfactory results of treatment. It is unwise to give up the application of this dressing too soon. One may, as an adjuvant to the ingredients of the paste, paint the skin, before the dressing is applied, with a 2 per cent. solution of ichthyol in water. This helps to brace up the blood-vessels. Before the dressing is finally abandoned one may, with advantage, intermit its application, leaving the skin exposed, except for a thin smear of paste, or coating of lotion, during the day, and covering it up at night with the complete dressing as before.

You are all sufficiently acquainted with the innate and rebellious tendency of eczema to relapse; indeed I think we may safely say that no case of eczema

ever proceeds uninterruptedly to a cure. We know how the cutting of a tooth, or the onset of menstruation will determine a recrudescence, and if the dressing is suspended too soon, and the irritating effects of the atmosphere or other noxious influence allowed to operate again too early, we have a recrudescence. When it has been found that the dressing may safely be stopped, the skin should be protected either by the application of a little calamine lotion, or ichthyol, 2 per cent. in linimentum calcis, or by smearing on a little paste. One is chary about allowing a patient who has had an acute eczema of the face to resume washing with soap and water, as the dilute solution of caustic alkali, which even the best soaps form, is very prejudicial to the skin, and may precipitate a relapse.

But there are types of eczema in which washing, even with strongly alkaline soaps, is of advantage. This was long ago pointed out by Hebra. I recently had under my care a very rebellious case of eczema of the scalp in a little girl. I succeeded in getting it well on several occasions, but it invariably relapsed, and the relapses were characterised by the copious out-pouring of foul-smelling sero-pus. Not even bichloride compresses sufficed to control the discharge, and destroy the odour, but the following combination rapidly cleaned up the scalp and effected a cure:—

I had the head rubbed all over with an ointment consisting of equal parts of unguentum sulphuris and *sapo mollis*; a few minutes afterwards it was thoroughly washed with *spiritus saponis kalini*, and it was then dressed with a sulphur paste as already described. The result was most gratifying, the odour and discharge speedily cleared up, and the child's scalp is now well. I am inclined to think that sulphur is more potent for the destruction of some forms of micro-organisms which infest the skin than even bichloride of mercury. I have carried out the same method of treatment in other forms of eczema of a chronic nature, with discharge, and have been equally well pleased with the results. In one case especially; that of an old man with several obstinate patches of eczema over the shin bone, this combination of treatments acted like a charm.

In acute eczema, as you have seen, the line of treatment I would advocate is that of rest and soothing applications. But chronic eczema requires a different course of procedure. For the sclerosed and thickened patch of eczema to which our forefathers used to apply liquor epispasticus, I have found that there is nothing like solid carbon dioxide snow. I shall quote two cases to illustrate the point.

A middle-aged lady had a persistent verrucose and lichenified eczema of the back of the right hand. It had resisted all the remedies which had been tried, *ung. picis liquidum*, *ung. hydrarg. nitratis dilutum*, and salicylic plaster among others, but it yielded to four applications of solid CO_2 , and the resulting skin was soft, smooth, and pliable. Another lady had two chronic patches of psoriasisiform eczema over the knee-caps, which were intensely pruriginous. The pruritus disappeared, and the sclerosed tissues melted down after two applications of CO_2 of a minute's duration each. In patches of eczema which have undergone lichenification, you will find CO_2 invaluable alike for subduing the itching and bringing about the resolution of the patch.

It has this specially to commend it, viz., it is infinitely cheaper and more easily procurable than radium, which was recently extolled so highly for this purpose by an eminent dermatologist. It is not always necessary to make a prolonged application of CO_2 .

Sometimes merely rubbing the patch over for 10-20 seconds with the cone of snow will suffice; but in this you must be guided by the individual case.

Dermatology was practically an unstudied department of medicine when the first edition of the "British Pharmacopœia" was issued, and in subsequent editions I do not consider that much has been done to elaborate suitable formulæ for the treatment of skin diseases. As a result, dermatologists have had to work out their own. I am an advocate of

simplicity in pharmacy. I do not consider anything is to be gained by the poly-pharmacy to which some dermatologists are addicted. To me it savours of drawing the bow at a venture, and shooting in the dark. I ask only for simple remedies; but I stipulate that they shall be properly applied.

There is one ointment in the "British Pharmacopœia" which I have found very valuable, and which I do not think is as generally used as it ought to be. I refer to the *Unguentum resinæ*. Combined with sulphur it is an excellent remedy for use in cases of chronic scaling eczema between the toes; and combined with *unguentum hydrarg.* it is very valuable as an application to ulcers, and to thickened patches of skin that require stimulating treatment. It is a tenacious and adhesive ointment, which I would venture to recommend to those of you who are not acquainted with it.

In bringing my remarks to a close I would thank you for the honour you have done me in inviting me to open your session. I trust that the session before us will be productive of much good work, and that many interesting cases will be shown at the meetings. Such a Society as this is of great educational value, for, after all, we are all students still, and in dermatology there are yet vast fields of knowledge to be explored. To me it has been a matter of great regret that those who claim to be in the forefront in the dermatological world have so often obstructed progress by "darkening counsel with words," by absurdities of nomenclature, and by an assumption of superiority and exclusiveness to which they have no title. Let us never forget that, as Newton said of himself, we are only children playing on the beach, and picking up here a pebble and there a pebble, while the great unfathomable ocean of knowledge rolls before us.

THE CLINICAL IMPORTANCE AND SIGNIFICANCE OF ACIDOSIS IN DIABETES.

By H. MONTLAUR, M.D.,

Of the Faculty of Medicine of Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

THE pathogenesis of diabetic coma is assuredly one of the most interesting problems in general pathology at present before the profession. As, however, our knowledge of the subject is added to and experimental research throws more light on obscure points, the subject unfortunately appears to become more complicated than ever. Nevertheless, it now appears to be clearly established that the cause of diabetic coma is to be sought in acid intoxication, or acidosis, although in truth we are still ignorant as to the exact share in its production that belongs to beta-oxybutyric acid and to the other products engendered thereby—viz., acetone and acetylacetic acid. These acetonic bodies which, in the diabetic, escape complete combustion, and their ultimate transformation into water and carbonic acid, are eliminated *via* the urine, and thus diminish the alkalinity of the blood. The presence of these acetonic products or generators of acetone, however, are held by certain observers not to explain all the features of diabetic coma, an opinion which, *inter alia*, is shared by Lépine and Morel. According to Lépine, the pathogenesis of diabetic coma is not wholly attributable to acid intoxication or acidosis; he believes that the intoxication is more complex than this, deriving both from beta-oxybutyric acid and other concomitant toxins. Hugouenq and Morel, on the other hand, in view of the fact that the reduction of the alkalinity of the blood due to the acidosis does not account for the production of coma, hold that the substances which tend to enhance the toxicity of the acetonic bodies belong to the quaternary derivatives of albumen. They call attention to the fact that in the diabetic subject the disassimilation of nitrogenous substances is, as a rule, exaggerated, and it may be conceded, they urge, that in this disease there is a disturbance of the general nutrition which bears not only on carbohydrates, but also on nitrogenous substances. They believe that the solution of the problem lies in the

products of disintegration of the molecule of albumen (the peptides), which are eliminated by the urine as part of the unestimated "organic residues." These peptides may be produced in unduly large quantities, or they may fail to undergo destruction, or it may be that, produced only in normal quantities, they are the outcome of an abnormal process of elaboration. We may add that Hugouneq and Morel are not concerned to dispute the importance of acidosis in the pathogenesis of diabetic coma, for this is a factor which it is impossible to overlook, especially as the treatment by bicarbonate of soda given by intravenous injection, though not uniformly successful, does often notably improve matters in diabetic coma.

Marcel Labbé and Louis Violle, who have investigated the comatogenous properties of various organic acids, arrived at the conclusion that acidosis is truly the principal cause of diabetic coma, and they showed that organic acids possess a specific toxicity apart from the toxicity incidental to their acid nature; in fact, the importance of these two kinds of toxicity is in relationship to their chemical constitution. The acid toxicity is always more pronounced than the specific toxicity and the toxicity of beta-oxybutyric acid which, according to these observers, plays the most important part in the production of diabetic coma, the acid toxicity stands for three-quarters of the total toxicity. Consequently, Labbé and Violle regard intensive alkalinisation of the organism as the basis of the treatment of diabetic coma. They hold, and so does Lépine, that it is of primary importance from the therapeutical point of view to recognise threatening acidosis in view of the oft-repeated observation that the alkaline treatment is often of no avail once the coma has actually supervened.

The most important element in the diagnosis of acidosis is the estimation of the urinary ammonia. The excretion of this compound is exaggerated in the diabetic who are called upon to combat acid intoxication and the reduction of the alkalinity of the blood. Under ordinary circumstances an individual on a mixed diet in the course of twenty-four hours eliminates in the urine from four to one gramme of ammonia, representing, on an average, from five or six per cent. of the total nitrogen. The presence of two or three grammes of ammonia is already an indication of a certain degree of acidosis, according to Labbé, and in presence of an intoxication culminating in coma we may get six to eight grammes, indeed Stadelmann mentions a case in which no less than twelve grammes of ammonia was excreted in the twenty-four hours.

Among other signs of acidosis obtained by urinary analysis, one of the most important is the amount of beta-oxybutyric acid which gives rise to acetylacetic acid and acetone. The quantitative estimation of this acid unquestionably affords most valuable information as to the amount of acetonetic products in the urine, but its application is difficult except in a research laboratory, and in practice it is not often available.

Magnus-Levy, it is true, has described a means of approximately ascertaining the amount of beta-oxybutyric acid on the basis of the amount of preformed ammonia in the urine. All we have to do is to multiply the weight of the ammonia by 6.12, in other words this observer finds that all the preformed ammonia is saturated by beta-oxybutyric acid. Certain it is that ammonuria in the diabetic stands in direct relationship with the excreted beta-oxybutyric acid, but other acid compounds are also saturated by this alkali, so that after all Magnus-Levy's process is only approximative.

From the clinical and eminently practical point of view, it is better to estimate the intensity of the acidosis by the colorimetric test, easy enough to apply, of diacetic acid, sometimes called acetylacetic acid, an intermediate compound between beta-oxybutyric acid and acetone. This diacetic acid is present in the urine as a very unstable acetylacetic ether. Its presence is revealed by Gerhardt's reaction, which consists in pouring a drop or two of the official solution of perchloride of iron into the urine, whereupon, if the urine contain not less than 15 centigrammes per litre of diacetic acid, it becomes of a reddish violet colour.

Hart has just devised a simple means of determining the existence of acidosis (index of acidosis) by the colorimetric estimation of diacetic acid. First of all we prepare a control tube containing ten cubic centimetres of the standard solution of 1 cc. of diacetic acid and 20 cc. of spirit in 1,000 cc. of distilled water. In another test tube of the same diameter is 10 cc. of the urine to be examined, and to each of the tubes we add 1 cc. of the official solution of perchloride of iron previously diluted with an equal volume of water. The tubes are set aside until the contents are quite clear, when we can compare the depth of the coloration. If the control tube containing the standard solution is lighter in colour than the tube of urine, water is added to the latter until the tint becomes the same, taking care to note the quantity of water added for this purpose. By the aid of the following table we can then ascertain the acidosis index per litre:—

10 cc.	correspondents to	1
15 cc.	"	1.5
20 cc.	"	2
25 cc.	"	2.5
40 cc.	"	4
100 cc.	"	10

The volumes of intermediate dilutions correspond to proportional indices.

This having been determined, all we have to do is to multiply the degree of acidosis per litre by the volume of urine emitted in the twenty-four hours, in order to obtain the degree of acidosis properly so-called.

By this method we can follow day by day the fluctuations in the excretion of acid generating acetone. The estimation of the preformed ammonia completes the evaluation of the acidosis. It has already been stated that ammonia excreted to the extent of two or three grammes in the twenty-four hours constitutes a state of acid intoxication which can be detected concurrently with the excretion of diacetic acid, thanks to the Ronchère rapid method of estimating the ammonia. This is based on the fact that formol, with an ammoniacal salt, gives hexamethylene tetramine, setting free the acid of the salt and thus enabling it to be readily titrated. With this information in our possession we can easily deduce the amount of ammonia that was in combination therewith.

For that purpose we take 10 cc. of urine diluted with distilled water so as to make 100 cc. This is exactly neutralised with decinormal soda solution in presence of phthaleine of phenol. We add 20 cc. of the commercial solution of formol, previously diluted with an equal quantity of water and neutralised. Into this mixture, by means of a graduated pipette, we drop decinormal soda solution until the phthaleine turns pink. The number of cubic centimetres of soda solution required to effect this is multiplied by 0.17, which will give the proportion of ammonia contained in a litre of urine.

We have not discussed the determination of the acetone in the acid intoxication of diabetics, because it is generally recognised that acetonuria, from the diagnostic point of view, is less important than diaceturia and ammonuria, and that, as a matter of fact, it does not afford a trustworthy indication of the degree of the acidosis.

SOME OBSERVATIONS ON CARCINOMA OF THE BREAST.

By S. J. ROSS, M.D., Ch.B.,

Surgeon to Out-Patients, Bedford County Hospital.

THE first case which I wish to record is that of a female, æt. 25, who had what appeared to be a simple adenoma of the breast. Microscopical examination, however, revealed the presence of a typical carcinoma.

The second case is that of a female, æt. 56, who had a small carcinoma of the right breast with adherent skin and retracted nipple. No axillary glands were to be felt. I removed the breast and

opened up the axilla, where I found enlarged glands along the axillary and subscapular vessels and along the outer border of the pectoralis major, this latter muscle I removed. I then discovered a small, hard gland near the coracoid process. The pectoralis minor was then removed, together with this gland and some surrounding fat. The wound was completely closed (no drainage being employed) and healed by first intention.

The third case was that of a female, *æt.* 56, upon whom I operated six years ago. The carcinoma of the right breast was very extensive, and axillary glands affected. The breast and both pectorals were removed and the axilla cleared. The wound healed by first intention, and there has been no local recurrence. Twelve months ago she began to suffer from dyspnoea and I aspirated two pints of blood-stained serum from the right pleura. During this illness she became absolutely bald. She remained comfortable for three months and then dyspnoea reappeared. I withdrew three pints of blood-stained fluid from the right pleura and two months afterwards four pints. The fluid has not re-accumulated; but there are obvious signs of mediastinal growth. The patient is rapidly losing flesh.

REMARKS.—These three cases appear to me of interest for various reasons.

The first case shows how necessary it is to make an immediate examination of tumours. We are apt to work by a rule-of-thumb method. Young patient, freely movable tumour, non-malignant. The first observation is correct, so also the second, but the deduction is by no means reliable and an erroneous deduction may cost the patient her life. We have no right to make a guess, if we have the means at hand of ascertaining a certainty.

The second case proves the importance of opening up the axilla in all cases of breast cancer, even if glands cannot be felt, and furthermore, having cleared the axilla it is absolutely necessary to carefully examine the region of the coracoid process. In this case there was one small gland, but microscopically it proved to be malignant. Had this been left early "recurrence" would have been certain. I am sure that whenever possible we should avoid drainage, even of an extensive wound, as we so frequently find a recurrence appears at the site of drainage. It is better to allow the patient to come round a little before closing the wound, and by so doing to ensure complete hæmostasis, than to keep the patient deeply under the anæsthetic until the final skin suture is inserted. We must remember that the danger of infection from without is greater than the danger of infection from within. The third case is interesting on account of the local wound remaining unaffected, the mediastinal affection progressive. The pleural invasion being at present "in abeyance," and the appearance of total alopecia, which has been followed by a rapid growth of hair during the past three months.

I firmly believe that as the precancerous stage of cancer is inflammatory, all breasts affected with chronic mastitis after the patient has reached fifty years should be removed. That no breast tumour should be regarded as simple until it has been proved so by microscopical examination. That the sooner we cease to worship the age incidence of malignant disease as a fetish, the better it will be for the patient and the reputation of surgery. That the sooner we recognise that the extensive wounds of breast amputations should be closed and not necessarily drained, the less frequently we shall hear of "recurrence" in the scar.

Merely to dissect away the pectoralis fascia when operating for breast cancer is to court disaster. When operating upon cases of cancer of the breast

we must be prepared for an extensive and tedious dissection; otherwise, we had better leave the case alone. In every case, however small the primary growth may be, we must remove the breast, open the axilla and clear away all glands and fat, and remove the pectoralis major, if we have the least doubt about the state of affairs around the coracoid process we should also remove the pectoralis minor. Finally hæmostasis must be complete; and drainage of the wound is to be avoided.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

CARCINOMA OF BREAST.—MR. WILLMOTT EVANS operated on a woman, *æt.* 49, for malignant disease of the left breast. For nearly nine months she had noticed in the left breast below and to the outer side of the nipple a small hard mass, which gradually increased in size. It caused but little pain, though she said that occasionally she felt shooting pains in it. On examination, the left breast was decidedly larger than the right, fullness being most marked in the outer and lower quadrant. The skin was slightly dimpled in this region, and the nipple was less prominent than in the other breast. On palpation there was felt a very hard mass about the size of a walnut. It was not separable from the rest of the breast substance, and was obviously attached to the skin. When the pectoralis muscle was put on the stretch by raising the left arm, and directing the patient to draw it down against resistance, it was clear that the mass was slightly attached to the muscle. On examining the axilla there was felt a little fullness on the inner side, but no definitely enlarged glands could be distinguished. The diagnosis, Mr. Evans said, was clear that carcinoma of the breast was present.

At the operation, the patient having been anæsthetised with ether, an incision was made from above the xiphisternal notch in a curved direction to the shoulder, passing about three inches above the nipple and reaching to a point an inch in front of the tip of the acromion process. A second incision, starting from the first about four inches from its origin, passed four inches below the nipple and joined the upper incision about three inches from its termination. The flaps thus marked out were raised, and then the axilla was cleared from above downwards, the axillary vessels being bared and the tendon of the pectoralis major divided near its insertion. Then the breast was separated at its margin and taken away, together with the greater part of the pectoralis major muscle. The bleeding was at times somewhat profuse, but was readily controlled with artery forceps. When all vessels were tied it was found that the edges of the flaps could be brought together nearly everywhere, but about the centre there was a small area two or three inches in extent which was not covered. However, by slightly undermining the flaps they could be adjusted so as to cover this area also. Catgut stitches were used. Gauze dressing was then applied, and bandages were put on to retain the dressings, but the arm was not fixed in any way.

Mr. Evans said that in every case in which a hard mass was felt in the breast of a patient over 30, the mass should be removed. If no other signs confirmatory of malignancy were present it was sometimes advisable to incise the growth before performing total removal of the breast, but if this were done, and the growth found to be malignant, the incision should be linted, and a completed set of fresh instruments should be used for the operation of excision, so that there might be no risks of infecting the wound by instruments which might have become contaminated by the incision of the malignant growth. The upper part of the incision, which is made for the purpose of clearing the axilla, should not pass through the axilla at all, for the skin in that region is not readily made aseptic, and, moreover, if the incision is placed high up on the shoulder a far better view of the contents of the axilla is obtained. It is advisable, he thought,

that all tissues which are to be removed should be taken away in one mass, and it is well to clear the axilla first so that when the breast itself is being excised there may be no risk of generalising cancer cells by manipulation of the breast. It was advisable, he considered, to cover completely the raw surface, but the skin incisions must be planned to insure the complete removal of the disease. By undermining the skin it is often possible to cover the raw surface completely, but if this could not be done, a skin graft a few days later would suffice. He regarded it as important that the arm of the patient should not be fixed in any way after the operation. Formerly, he pointed out, it was customary to bandage the arm to the side, and some surgeons now fastened the patient's wrist to the head of the bed; but both these methods, he thought, tend to lead to subsequent stiffness. It was far better, in his opinion, to let the patient place the arm in the position she preferred, and when this was done there was a minimum loss of mobility after the operation. With regard to the general question as to what cases of cancer of the breast should be operated upon, he considered that cases of carcinoma of the breast might be divided into four classes. In the first class were those cases in which the tumour was of recent appearance, not of rapid growth, with no adhesions to the skin or muscle, and with no glands in the axilla; in these cases the prognosis was exceedingly good, and if the complete operation were done the vast majority of patients would be permanently cured. In the second class were those cases in which the duration of the disease was a little longer, the skin was slightly adherent, and there might even be some adhesion to the muscle, but no glands could be felt in the axilla; in this class it was right to urge an operation on the patient, for if an operation were done at once there would probably be no recurrence in 50 per cent. of the cases provided the complete operation were performed. In the third class, not only was the skin adherent to the tumour, and the tumour itself attached to the muscle, but palpable glands were found in the axilla; in these cases the chance of cure by operation was materially less; but still if the patient was made to understand that the chances of perfect recovery were small, an operation was justifiable. In the last group would be cases with a long history or with very rapid growth of the tumour, which was firmly adherent both to the skin and to the muscle, and the axilla was occupied by a large mass of glands; all operation was useless. Mr. Evans did not consider that malignant disease was in the least hereditary, and the fact that a relative of the patient had died of malignant disease did not affect his diagnosis in any way.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

MEETING HELD OCTOBER 11TH, 1912.

The President, SIR WILLIAM OSLER, BART., in the Chair.

DR. A. M. GOSSAGE showed a woman, *æt.* 53, the subject of

COARCTATION OF THE AORTA.

The patient was the same as that exhibited at the last meeting of the section by Dr. Langmead.

MR. H. MORRISTON DAVIES showed a man, *æt.* 47, illustrating the favourable results of

ARTERIOVENOUS ANASTOMOSIS FOR GANGRENE DUE TO SYPHILITIC ENDARTERITIS.

This patient was shown at a meeting of the Clinical Section a year ago. The history of the case was briefly as follows:—He had had syphilis and had been a heavy drinker. He first noticed pain in the left foot and discoloration of the middle toe in March, 1911. The toe became gangrenous and was amputated in June, and the wound was left open. At the begin-

ning of August two further patches of gangrene appeared, one on the inner side of the fourth toe and one on the outer side of the second toe. The foot was cold and painful, and there was purple discoloration of the great toe, the dorsum of the foot, and round the head of the fifth metatarsal; the amputation wound was unhealed. An arteriovenous anastomosis was done in Hunter's canal on August 15th, 1911; the proximal end of the superficial femoral artery being united to the peripheral end of the femoral vein and the proximal end of the vein and distal end of the artery being ligatured. The pain and discoloration disappeared after the operation, the foot became warm, the gangrenous patches separated off, and the wound at the base of the middle toe healed. The patient began walking a month after the operation and was discharged from the hospital after another four weeks. A week later he was readmitted under Sir J. Rose Bradford, suffering from a right-sided hemiplegia and aphasia, thought to be probably due to syphilitic thrombosis and to be unconnected with the anastomosis. The patient had slowly recovered from this attack, and had been able to walk with the help of a stick for some months. The condition of the left foot had remained good. There was, when exhibited almost fourteen months after the operation, no pain, discoloration, or oedema. The patient had a chillblain on the great toe of the left foot last winter, but that cleared up completely.

DR. A. E. GOW, for DR. W. P. HERRINGHAM, showed two brothers exhibiting.

UNUSUAL RASHES.

The patients were aged 5 and 2 respectively. The younger was shown by Dr. Adamson before the Dermatological Section of the Society in May of this year. Both children, from a few months of age, had dusky hands and feet and an eruption. This eruption had become much less marked during the past few months in the elder boy, and with its subsidence the interphalangeal joints, which were previously swollen, had become red and painful. The character of the eruption was briefly as follows:—On the forearms, hands and legs were papules about 3 mm. in diameter, reddish-brown in colour; papules, 5 mm. in diameter, with black crusts in the centre; circular, crateriform areas 10 mm. to 30 mm. in diameter, with raised, reddened margins and a large central scar; several healed lesions resembling vaccination marks. The papule apparently evolved through its stages in from two to three weeks. The elder child had never been able to walk properly, probably owing to genu valgum, which had become worse during the last year, and he was stated to have lost flesh during this time. There was a fusiform peri-articular swelling on all the fingers. A skiagram showed no alteration in the bones. There was no muscular wasting, the nails were natural and the tendon reflexes brisk. There were a few palpable glands in the anterior triangles of the neck. The spleen was not palpable, and there was no fever.

It was suspected that the lesions were of the nature of a tuberculide. Von Pirquet's cuti-reaction was negative, but after injection of 0.0002 c.c., 0.0005 and 0.001 c.c. of old tuberculin there was a general reaction with rise of temperature to 101.4° F. in the case of the younger boy. There were, however, both previously and subsequently, unexplained rises of temperature. The elder showed no reaction to tuberculin, even with a dose of 0.004 c.c. The Wassermann reaction was negative in each case, and the blood showed no cytological change. As a result of treating the younger brother with tuberculin (T.R.) there was local reaction in the spots, and many healed without passing through the scab stage, the resulting scar being not nearly so marked.

THE PRESIDENT showed a girl, *æt.* 20, illustrating

CIRCULATORY DISTURBANCE WITH CERVICAL RIB.

In February, 1912, she had fallen and bruised the right elbow, apparently not a serious injury. About the end of May she had noticed that after using the right arm it became darker in colour, the hand swelled, and the veins of the neck became distended. She

looked well; physical examination of the chest and abdomen negative: no enlargement of the glands. The right pupil was a little larger than the left. At rest the right arm looked natural, but measured above the elbow $\frac{3}{4}$ in. more than the left. There was no atrophy of the muscles of the hand; sensations were perfect. After using the muscles of the right hand for a few minutes the following changes occurred: The skin reddened, at first on the inner side above the elbow, then the redness became general; the arm swelled, increasing $\frac{1}{4}$ in. by measurement; the pulse in the right radial became smaller, the blood-pressure fell from 115 mm. of mercury to 90 (it was normally a little less than on the left side), the veins in the neck became enlarged, particularly the external jugular, and there was prominent venous swelling above the inner end of the clavicle. Continuing the exertion, the arm felt numb and dead and she had to rest.

The X-ray pictures showed cervical rib on both sides, the right a little longer, both of moderate size. The case belonged to a group of cases of cervical rib which he had described, in which the arm is normal when at rest, but on exertion becomes swollen and livid, and muscular effort has to cease—features resembling the condition known as intermittent claudication. In many cases of cervical rib the subclavian has been compressed in the angle between the rib and the scalenus anticus. In the present instance the rib looked short, but it was possible that there might be a cartilaginous extension. When at rest, and with slight muscular effort, sufficient blood reached the limb, but the demand for increased blood flowing upon exertion was not met, and there was stiffness with numbness and vascular changes. Cases have been reported suggesting Raynaud's disease, and Keen states that there are at least seven instances of local gangrene of the finger associated with cervical rib.

Dr. F. PARKES WEBER showed a case of

GIANT URTICARIA OF FIVE YEARS' DURATION.

The patient, a man, *æt.* 31, was subject to swellings or various sizes, which might affect any part of the surface of his body, and were generally accompanied by a sensation of itching. The skin over these swellings is always more or less reddened. The swellings were sometimes large enough for a single one to cover the whole of a shoulder or a buttock. Sometimes the swellings succeeded each other so quickly that he did not become free from them for any length of time. Muscular exertion favoured their occurrence. Scratching made them worse. Diet apparently played no part in inducing them. Temperature (cold bathing, etc.) seemed to make little difference. The swellings sometimes lasted two or three days, but sometimes they disappeared within twelve hours. The patient said that as yet nothing has done him any good, and that the affection was neither better nor worse than it was when it commenced about five years ago. There was no history of any similar disease in others members of the family, as there often is in typical cases of angio-neurotic oedema.

Dr. WEBER also showed a case of

MULTIPLE CALCIFICATION ("CALCINOSIS") IN THE SUBCUTANEOUS TISSUE.

The patient was aged 7, and had been admitted to the German Hospital for a number of hard nodules in the subcutaneous tissue of the extremities and the portion of the trunk adjoining the extremities. Most of the nodules were smaller than an average pea, but some were much larger, having apparently arisen by the coalescence of several smaller nodules. The face, head, thorax and abdomen are practically free. The nodules, as a rule, gave rise to no pain or tenderness, and seemed to have developed without the child being aware of their existence. The lymphatic glands in the groins and right axilla, and some in the neck, were moderately enlarged.

The nodules were first noticed 15 months ago, and many others had appeared since. One little nodule near the right knee became very prominent and discharged spontaneously.

That the subcutaneous nodules consisted largely of

carcareous material had been proved both by Röntgen-ray examination and by chemical analysis. The nodules occasionally became inflamed and softened and the skin over them adherent. Two such softened nodules had been excised and examined. The gritty material was found to consist of calcium carbonate and calcium phosphate. No tubercle bacilli or other microbes could be detected in the contents of the nodules. Microscopical sections of a softening nodule showed that the nodules consisted of a sponge-like matrix of subcutaneous connective tissue in the interstices of which the granular particles were embedded. "Calcinosis" was probably the most convenient term to be used for the disease in question, and more advanced cases had been described under the headings "calcinosis interstitialis," and "calcinosis universalis." Apparently the chief danger was the risk of septic infection associated with the "breaking down" and discharge of the calcareous nodules.

Dr. H. BATTY SHAW and Mr. PERCY HOPKINS showed a boy, *æt.* 7, with (a) double-jointedness, (b) dermatolysis ("elastic skin") with great friability of the skin and excessive tendency to bruising, (c) multiple subcutaneous tumours on the limbs (? fibromata, ? neuromata). The joints were very loose, and the child took particular pleasure in forming almost circles by locking the index and middle fingers of each hand. He was somewhat pigeon-chested, and there was marked lateral curvature of the dorsal spine, with the convexity to the left. The skin was soft and could be drawn readily from the limbs and body, as in the condition known as dermatolysis, or "elastic skin." Numerous small subcutaneous nodules could be defined in the limbs, from the size of a small millet seed to that of half a pea. They were not painful, and were not restricted to the neighbourhood of the joints, nor apparently to the large nerve-trunk. Bruising was very readily produced even by moderate pressure; the mere holding of one upper arm on the occasion of the first visit was followed by several hand-marked bruises observed a few days later. He fell readily on attempting to walk quickly or to run; the fronts of the knees and the chin bore evidence in the form of scars. Quite small falls caused the skin to rupture. So far as either parent knew, there was no other example of such a condition in any member of their respective families.

Mr. LAWRIE H. MCGAVIN showed a patient illustrating

ABDOMINO-PERINEAL EXCISION OF THE RECTUM: TRANSVERSE COLOSTOMY.

Eighteen months ago the man, *æt.* 57, was admitted with carcinoma of the second part of the rectum, causing much pain on defecation. The growth was a large cauliflower mass, bleeding readily, and very slightly attached to the sacrum. Under chloroform a transverse colostomy was performed, and the abdomen having been opened, both internal iliac arteries were ligated. The sigmoid colon was divided between ligatures, the end of the upper section being inverted. The end of the lower portion was carbolised, tied up in gauze, and after the bowel had been stripped into the pelvis, was returned to the pelvis and the abdomen was closed. In the lithotomy position, the anus having been closed, the bowel was removed *via* the perineum. A tear occurred at the site of the growth, which was here more fixed to the sacrum than had been thought. Some infection of the wound occurred, but the suppuration was confined to the superficial layers. The bowel was opened on the third day. The patient had made a good recovery.

Mr. MCGAVIN also showed another successful case of the same condition, in which the operation had been performed on a woman, *æt.* 67. Spinal anaesthesia had been employed almost exclusively. The operation had been done 16 months before. Also the following cases:—*Torticollis following mumps and associated with bilateral cervical ribs*, in a girl, *æt.* 11. He thought that the condition was probably rheumatic and unconnected with the abnormal ribs. *Oblique fracture of the femur into the knee-joint and of both tibia and fibula.* Arthrotoomy had been performed

and the condyles of the femur united by screws. The patient was a man, æt. 48, who had been struck by a swinging balk of timber. The displacement of the femoral fragment had been so bad that three inches of shortening had existed. *Serous cyst in the ramus of the mandible.*—This had been evacuated and its lining membrane removed. Microscopical examination gave no clue as to its nature.

Mr. MCGAVIN also exhibited an apparatus which he had devised for exerting extension on the fragments in cases of fracture in the length of the tibia. This apparatus could be placed on the operating table, the operation of plating and screwing being carried out upon it, when, by exercise of tension obtained by the screw, the fragments have been brought into line. By its use the operation, especially in cases of old oblique fractures, was greatly facilitated, and the time of operation much reduced.

Mr. PAUL B. ROTH showed a carman, æt. 54, with TRAUMATIC MYOSITIS OSSIFICANS.

An ossified mass occupied a position in front of the right femur. Its upper part was attached to the bone, but its lower was fragmented, and seemed to be free in the muscle. It had followed a kick from a van-horse.

Dr. F. E. BATTEN showed a case of TREMOR: ? NATURE.

A man, æt. 43. In December, 1911, he had an attack of swelling, pain and redness, involving chiefly the hands, to a much less extent the feet, lasting about a month. In August, 1912, he had a second similar attack of about a month's duration.

Shortly after the second attack his arms and legs began to shake slightly, both at rest and on movement. The shaking gradually increased, especially on the right side, and reached its height in about a month. He was then unable to hold anything in his right hand, and his right leg appeared to drag. Since then the shaking had lessened somewhat, especially on the left side. He complained also of occasional painful cramps on the dorsum of the right foot.

The patient's emotional state is decidedly exalted. The tremor affected all four limbs and persisted during rest. It increased by movement and when the patient felt himself observed. The tremor of the right hand when at rest was coarse, wide, rapid, consisting chiefly of rhythmic lateral movements at the wrist, with accessory accompanying movements at the elbow and shoulder. The static oscillations were chiefly in a vertical axis, and sometimes became so violent and rapid as to obscure altogether the outline of the hand. The movement tremor resembled the intention type in that the oscillations became more violent and of wider range towards the close of the act. He considered the tremor was functional and unconnected with organic disease.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

MEETING OF THE THIRTY-FIRST SESSION, OCTOBER 4TH, 1912.

The Retiring President, Mr. W. McADAM ECCLES, in the Chair.

BEFORE PROCEEDING to the business of the evening, the chairman referred to the great loss sustained by the Society, since its last meeting, through the unexpected death of Mr. Leonard Bidwell, a past President of the Society, and a vote of condolence to Mrs. Bidwell and family was passed by the members present.

Mr. McADAM ECCLES then inducted the new President, Dr. G. P. Shuter, and the latter presented the retiring President with the "Kectley Memorial Medal"; a medal presented to each retiring President as a memento of his tenure of office, and Dr. Shuter, speaking on behalf of members, hoped Mr. Eccles would look upon it as an acknowledgment in some degree of the great services he had rendered to the Society.

Some further business having been transacted, Dr. SHUTER delivered his inaugural address on the

HISTORY OF NITROUS-OXIDE ANÆSTHESIA.

After some preliminary remarks, he traced its history as an anæsthetic through three periods, the first commencing in 1800 with the publication of Davy's researches, and ending with its application by Horace Wells to practical use in dentistry in 1844; the second period from that date to its revival in 1864; the third period from its revival to the present day.

Priestley discovered the gas in 1774. Humphry Davy observed all the usual symptoms resulting from its inhalation, and at the age of twenty-two published his researches. Towards the end of his essay Davy makes this remarkable suggestion, remarkable as showing his power of reasoning and deduction, but more remarkable in that the passage, although it must have been read by thousands, was never acted on. He says, "As nitrous-oxide in its extensive operation seems capable of destroying physical pain, it may probably be used with advantage in surgical operations in which no great effusion of blood takes place."

Davy was the most popular and eloquent lecturer of his day, at a time when lectures were the fashion, and a good lecturer was much sought after. His experiments were repeated by innumerable imitators to such an extent that it was a common event for itinerant showmen to entertain an audience at a country fair by chemical experiments, and one that never failed to cause amusement was the inhalation of "laughing-gas," and in America entertainments called "ether frolics," or "laughing-gas frolics," kept alive the knowledge of the curious action of nitrous-oxide and ether. Thus the modern practice of anæsthesia was born.

On December 10th, 1844, Dr. Colton, a pupil of Professor Turner, of University College, London, a popular itinerant lecturer on chemistry, went to Hartford, Connecticut, and delivered a lecture on "laughing-gas," and Horace Wells, an enterprising dentist in that town, being much impressed by what he saw and heard, conceived the idea that a tooth might be removed painlessly under its influence. He determined to put the matter to the test without delay, and the next morning invited his friend Dr. Riggs to pull one of his molars after Colton had administered gas. Elated with the success of the experiment, he declared it to be the greatest discovery ever made—a new era in tooth-pulling! Success followed for a time, but soon a demonstration in Boston resulted in a failure, and Wells was treated as a cheat and an impostor. Easily depressed as he had been elated, he never recovered from his disappointment, and after being reduced to want and actual starvation, died, by the irony of fate, under the influence of the anæsthetic introduced by his pupil, partner and rival, Morton. It would be difficult to picture a more melancholy and pathetic figure than Horace Wells, but this tragedy must not fill our vision to the complete exclusion of the patient work of Colton, who not only inspired Wells with his brilliant discovery, but was responsible for the most practical improvements in its administration, and for its revival in America, France and England.

During the next twenty years little progress was made, until, in June, 1863, Colton happened once again to be lecturing in Newhaven, Connecticut, and exhibiting the "laughing-gas," as usual, when Dr. Joseph H. Smith, who practised in the town, obtained his assistance for the extraction of seven teeth in the case of a lady patient in a very delicate state of health, to whom he did not wish to give ether. The teeth were extracted without the patient being sensible of any pain, and during the next three months 3,929 teeth were extracted without any ill effects. Colton was now an expert and imparted skill and knowledge to his pupils. In July, 1863, he moved to New York, and in the course of three years administered gas 17,601 times without mishap. By 1863 the use of nitrous-oxide was general all over the United States.

In July, 1867, Colton journeyed to Paris, where his teaching was received with enthusiasm, and in the

following March one of his pupils, Evans, gave a demonstration of the new anæsthetic, as it was called, at the Dental Hospital, Soho Square. Other demonstrations quickly followed, and Paget, who witnessed an exhibition at St. Bartholomew's Hospital, made this wise and cautious comment: "After seeing Mr. Coleman give nitrous-oxide, I cannot doubt its sufficiency for procuring total insensibility to the pain of short operations. The appearance of asphyxia is alarming, but it is so brief that one may believe that even if it were profound it might do no harm. The question of danger, however, can only be decided by the results of some thousands of cases."

By August 1st, 1868, it was permanently installed in all the large London Hospitals, so that its spread was even more rapid on this side of the Atlantic than the other, in spite of warning notes sounded by some surgeons and physicians, and notwithstanding powerful opposition in certain quarters, the extended use of nitrous-oxide for more serious and prolonged operations made uninterrupted progress.

Gas was administered to the first dental cases with the same primitive apparatus that was used in laboratory experiments—simply an ox-bladder, in which was fixed a wooden tube as a mouthpiece. Anæsthesia was secured by pressing the lips round the wooden tube and holding the nose to compel the patient to breathe to and fro into the bag. When Colton insisted on a plentiful supply of pure gas and introduced his inspiratory and expiratory valves the future of nitrous oxide was assured. Colton discovered the necessity of the complete exclusion of air to procure rapid anæsthesia, and the necessity of correct proportion of air to maintain a quiet anæsthesia for a prolonged operation. He noted, too, that vomiting after mouth operations was frequently due to the blood which had been swallowed. Coleman found that long anæsthesia followed a long induction after removal of the face-piece, and that it was advantageous to give a small quantity of air during induction for this purpose.

Clover invented new instruments and made improvements in others which are in use to-day. He also gave directions for preparing patients for operations; he classified the signs of anæsthesia, and he taught how to interpret and make use of them. He shrewdly anticipated nitrous-oxide and oxygen anæsthesia by fitting a valve for regulating the percentage of air, and the administration of nitrous oxide was placed, within a few months, on such a sound footing that little alteration in our methods has been required by later additions to our knowledge.

In conclusion, Dr. Shuter reviewed the evolution in the preparation and supply of nitrous oxide. At first surgeons and dentists made their own gas; later this was sold by Bell and other chemists in large rubber bags, and when at length the demand was sufficient to make it pay, Mr. George Barth solved the difficulty. He was already selling compressed oxygen for medical purposes, and it was a small step to treat nitrous oxide in a similar fashion. Finally, Mr. Orchard supplied liquefied gas under safer conditions. It is of interest to note that Evans was the first to make use of gas in the liquid condition. In June, 1868, he paid a second visit to the Dental Hospital and brought over with him from Paris a quantity of liquid gas in a bronze bottle. It was here he made the further suggestion that the liquid gas might be used for producing local anæsthesia.

A hearty vote of thanks, proposed by Mr. F. SWINFORD EDWARDS, and seconded by Mr. RICKARD W. LLOYD, was accorded to Dr. Shuter for his interesting address.

The following cases were shown and discussed at the meeting:—

By Dr. Leonard Dobson: a case of angio-neurotic œdema.

By Mr. N. Bishop Harman: (1) a case of senile cataract followed six days later by vitreous hæmorrhage—recovery; (2) a case of pneumococcal hypopyon ulcer treated with a mixture of pure carbolic acid and camphor (equal parts).

THE
NEW LONDON DERMATOLOGICAL SOCIETY.

MEETING HELD OCTOBER 10TH, 1912.

The President, Dr. P. S. ABRAHAM, in the Chair.

THE opening address was delivered by Dr. G. STOPFORD-TAYLOR, of Liverpool, on

SOME PRACTICAL POINTS IN THE TREATMENT OF ECZEMA, which is published in full on p. 402.

THE PRESIDENT, in thanking Dr. Stopford-Taylor for his practical and useful paper, said that most dermatologists were now agreed that traumatic inflammations of the skin were indistinguishable from ordinary eczema. The toxins from certain septic organisms were also frequently responsible for outbreaks of eczema. He considered that starch poultices, as introduced into dermatology by Professor Allan Jamieson, of Edinburgh, were of great value, but he was rather afraid of the irritating effect of boric acid in some cases.

Dr. H. SAMUEL thought that the more one understood the more one tended to exclude the word eczema.

Dr. SERRELL COOKE was interested to hear the remarks of Dr. Taylor upon the use of Ung. Resina. He had often employed it to abort boils.

Dr. DAVID WALSH said that it seemed to him curious that we had no really satisfactory definition of eczema. He was interested to hear in the question of the occurrence of erythematous rashes in connection with wounds of the skin. According to his view, expressed many years ago, this was an excretory irritation, due to the absorption of some septic poison. Dr. Taylor had regarded this phenomenon as nervous. Why not assume that the toxin acted directly upon the skin? Few of us would admit, for instance, that a copaiba rash was a nervous phenomenon. He called attention to the fact that many of the modern remedies used in dermatological practice were far more heroic than those formerly employed.

Dr. DENNIS VINRACE thought that universal specialisms were impossible. If dermatology were introduced into the medical curriculum as a compulsory subject, other portions would have to be somewhat thinned.

Dr. ALFRED EDDOWES did not mean a very definite thing when he referred to eczema—not like small-pox, for instance,—but he regarded it more as a symptom. Eczema was, in fact, a moist catarrh, a true dermatitis, but every case of dermatitis was not one of eczema. In very chronic cases he had obtained good results with mercurial plaster. He emphasised the need for keeping clear the lower bowel, especially in cases of the nervous type,—Brocq's *neuro-dermite*.

Dr. C. G. MACK alluded to the lack of dermatological teaching in former times, and he thought that the diagnosis often brought by patients' friends as having been given by general practitioners should always be accepted with reserve.

Dr. J. D. P. McLATCHIE inquired as to the use of liquor potassæ in cases of chronic eczematous patches.

Dr. WILMOTT EVANS regarded a mechanical, irritative dermatitis as identical with an eczema. He considered that it was wrong to give it another name, merely because the cause happened to be known, just as an exudative synovitis might result from a number of causes, so might eczema. He thought that the role of the nervous system had been rather overworked as a theory, for in many cases the cause of the disease was internal. For that reason, therefore, the treatment could not be limited to the skin.

Dr. STOPFORD-TAYLOR after having briefly replied, then read

NOTES OF A CASE OF DARIER'S DISEASE,

illustrated by lantern slides. The patient had been previously exhibited before the Society. Dr. Taylor also showed slides and casts of an apparently hitherto undescribed disease, characterised by the appearance

of fine, waxy ridges and papules all over the surface of the trunk and face in a woman. It is hoped to publish an account of this unique case.

Dr. Eddowes exhibited some interesting drawings and photographs of diseases of the nails and other skin affections, and a series of water-colour drawings were exhibited by Dr. Walsh to illustrate his views upon the association of heart disease with many forms of chronic or recurrent skin eruptions.

CENTRAL MIDWIVES' BOARD.

SIR FRANCIS CHAMPNEYS presided at the monthly meeting of the Board on Thursday last, October 10th. The correspondence included a letter from the Clerk of the Council conveying the approval of the Lords of the Council of the fixing the scale of the present Secretary's salary at the following rate—£600—by annual increments of £25—to a maximum of £750—to take effect from the 1st April, 1912.

At the request of the Board, the Chairman agreed to write to Lady Sinclair, conveying the sympathy of the Board in her bereavement.

A letter was read from Dr. Harry Stokes, of New Wortley, Leeds, whose application for recognition as a teacher was refused by the Board at its meeting on July 25th, asking the Board to reconsider the matter. A letter was also read from Miss Violet Thurstan, County Superintendent of the West Riding Nursing Association, supporting Dr. Stokes's application.

The Board adopted the recommendation of the Standing Committee: "That, having heard and considered the new facts which have been brought to its notice regarding the West Riding Nursing Association, Dr. H. Stokes be recognised as a teacher."

No action was taken in the matter of a letter from a candidate who failed at the August examination, complaining of unfair treatment on the part of an examiner.

COMPULSORY ATTENDANCE OF MEDICAL MEN IN MIDWIFERY CASES.

A letter was read from a certified midwife, practising in Chesterfield, complaining of the issue by the Chesterfield Division of the British Medical Association of a circular, with reference to the conditions affecting the practice of midwifery in that town.

A letter was read on the same subject from a medical practitioner in Chesterfield, upholding the midwife. The circular contained instructions that no midwife should engage her services for any confinement without first sending the patient to a doctor, who was to examine her, and receive a fee of 5s. In the event of his assistance being required at the confinement, his fee would be one to two guineas, from which the 5s. would be deducted. There were various details connected with this compulsory employment of the doctor, and the circular concluded with a threat to report all midwives who did not conform to them, to the British Medical Association and the Midwives Union. It did not state what authority these bodies held over midwives. The reason alleged for the issue of these rules, was, that the safety and welfare of mothers and children was of first importance; and a recent inquest had been held on a woman who had died in childbirth, because the doctor refused to go when he was sent for by the midwife.

The Board resolved to reply (1) That, if the midwife has obeyed the rules of the Board regulating the summoning of medical aid, she has discharged her duties to the patient; (2) That the Board has no authority over medical practitioners. It was also agreed (3) That the correspondence be forwarded to the Privy Council.

In reply to a complaint from Dr. Maxwell, one of the Board's examiners, of a circular issued by a midwife, he was informed that no rule of the C.M.B. had been infringed by the advertisement referred to, which merely stated that the midwife "attended confinements with and without a doctor." There was some correspondence relating to the administration of the

Maternity Benefit under the Insurance Act, and the payment of medical men called in on the advice of Midwives. In reply to a question, it was stated: That the Town Councils of Liverpool, Manchester, and Cardiff have made agreements with all the medical men in their districts for a fee of one guinea all round, when summoned to a case attended by a midwife, and that elsewhere the fee varies. That the authority by whom the fee is paid is the Local Supervising Authority in Liverpool, Manchester and Cardiff, and the Guardians in some other places.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Oct. 12th, 1912.

TREATMENT OF BOILS.

THE region is washed with soap and water, dried, and a drop of the following solution is placed on the centre of the boil:—

Iodine, 1 dr.

Acetone, 3 dr.

Let stand a week before using. The mixture becomes blackish and syrupy and no longer irritating. Later, if the boil does not recede, a dressing of glysiate of starch and boric acid (1-10) on absorbent wool is applied.

PAIN IN THE SIDE.

Consumptive patients frequently complain of a pain in the side, generally due to the irritation of some nerve. A treatment as efficacious as it is simple consists in injecting half a drachm of boiled water *loco dolenti*. Generally one subcutaneous injection suffices and the pain disappears in from 20 to 30 minutes.

ERYSIPELAS.

The parts are painted once a day with—

Tincture of iodine, 1 oz.

Guaicol, $\frac{1}{2}$ dr.

If a small skin forms it can be removed by glycerine. Under the influence of this treatment the skin wrinkles and desquamation commences towards the fifth or sixth day, when the applications are suspended.

HÆMORRHOIDS.

The medical treatment of piles is internal, external and dietetic. Dr. Duba's method is as follows:—

Glycerine, 1 oz.

Linseed tea, 1 qt.

A wineglassful is taken every hour for the first three days of the inflammatory period; an improvement sets in on the second day. On the fourth day, if the state of the kidneys allows it, one of the following wafers is taken before each meal:—

Salicylate of soda, 10 gr.

Benzoate of soda, 10 gr.

Exalgine, 2 gr. No. 20.

If at the end of that time, and with concomitant external treatment, the cure is not complete, it should be recommenced.

The external treatment consists in sitz baths morning and evening, with 1 lb. of bicarbonate of soda, followed by the application of four or five leeches provided the condition of the patient permits it, after which the parts are painted with—

Cocaine, 10 gr.

Ext. of belladonna, 15 gr.

Ext. of hyoscyamus, 15 gr.

Glycerine, 5 dr.

and covered with a wet dressing and oil silk. When the inflammation subsides (three days), the following lotion is applied after the painting:—

Calomel, 1 dr.

Solution of adrenalin, 2 dr.

Lime water, 6 oz.

A plug of cotton wool moist with this solution is applied for three or four minutes each morning. At night the parts are powdered with—

Oxide of zinc, 2 oz.
Powdered opium, 1 dr.
Naphthol B., 2 dr.

Dietetics.—First three days, milk diet; lacto-vegetarian diet for ten days more, after which the patient may return to his usual *régime*. Rest in bed is necessary for a few days.

GERMANY.

Berlin, Oct. 12th, 1912.

At the Gesellschaft für Psychiatrie und Nervenkrankheiten, Hr. Bürger showed preparations from a case of hæmorrhage into the pons and medulla after
POISONING BY METHYLIC ALCOHOL.

The speaker had examined carefully the pons and medulla in three undoubted cases of poisoning by methyl alcohol as the clinical symptoms, especially the laboured breathing and the regular death by paralysis of respiration, pointed to the disease of these parts and especially the nucleus of the vagus. There was extensive hæmorrhage into this region, as Rühle saw in cases of methyl alcohol poisoning in dogs. It seemed that these hæmorrhages were regularly met with in such cases of poisoning. Even in acute cases of alcoholic poisoning there were hæmorrhages into the central nervous system, but in the ordinary alcoholic poisoning no special preference was shown for the medulla or the region of the vagus such as was the case in poisoning by methyl alcohol. The hæmorrhages therefore had a pathological significance, inasmuch as they were a confirmation that a particular death was due to poisoning by that form of alcohol, and also a clinical significance as they assisted us in arriving at a correct understanding of such cases. Sudden death by paralysis of respiration, which often took place like lightning from a clear sky, might be caused by hæmorrhage into the medulla oblongata, in the region of the vagus. Hæmorrhage into the nucleus of certain nerves might be the cause of paralysis of isolated muscles such as those of the eye, of the eyelid, such as actually did take place at times. From a therapeutical point of view hæmorrhages into the central nervous system, both in poisoning by methyl alcohol and in the more usual form from ethyl alcohol, were a reminder that we should relieve the system of the poison at the earliest possible moment.

Hr. Bonhoeffer said that exactly similar hæmorrhages to those described by the reader of the paper were also met with in the region of the aquæduct and the pons in extreme deliriums, and generally in severe intoxications, both of auto-intoxications and those from external causes. There was therefore nothing specific in the condition; they ranged themselves amongst the anatomical conditions of polioencephalitis hæmorrhagica superior in the sense of Wernicke's cases.

The difference was chiefly of a quantitative kind in so far as the injury produced by the methyl alcohol seemed to be very severe.

Hr. Marcuse had met with a similar condition in a fireman, who had been poisoned by smoke. Several weeks after the intoxication paralysis of the ocular muscles took place, which announced a most unfavourable course of events.

Hr. Bürger asked if in Hr. Bonhoeffer's cases of hæmorrhage in delirium tremens and poisoning by sulphuric acid death had been preceded by convulsions?

Hr. Bonhoeffer replied that the condition mentioned had been quite independent of epileptiform convulsions. It had occurred in cases of delirium, not as a direct effect of the alcohol, but as a secondary antitoxic poison which had developed on the basis of chronic alcoholism and led to the deliriums.

TREATMENT OF WOUNDS OF THE PERITONEUM.

(Continued Discussion.)

Hr. H. Grusdew, Kasan, said that washing out of the peritoneal cavity after laparotomy was useful to all appearance when non-virulent pus was present in the abdominal fluid, also in those cases in which the abdomen contained blood, fluid from cysts, intestinal contents, etc.

When, on the other hand, there was recent pus containing, for example, streptococcal pus, washing out was extremely harmful as it generalised the poison. Here the pus should be removed with dry compresses, and the infected spot should then be covered or shut off from other parts by gauze drains. For washing out Locke's solution was the best at a temperature of 37.8.

Hr. Josephson, Sweden, said that cancer of the cervix should be treated before commencing a laparotomy. Disinfection of the hand by iodine was not dangerous to the peritoneum. Pure gonorrhœal free peritonitis was not dangerous to life, but as it was often called forth by mixed infection, unless this was at once excluded, laparotomy should be resorted to without delay.

In post-operative peritonitis the abdomen should be re-opened immediately. The indications were difficult to determine. It was therefore best to be guided by the functional activity of the bowel, and if signs of paralysis appeared a "Witzel's" fistula should be set up. In infective peritonitis the point of infection should be at once removed. Excessive washings out, emulsions, "milking" of the bowel should be avoided. In puerperal streptococcal peritonitis we should only achieve something in cases of sudden rupture of a pyosalpinx or other perforation; in the creeping form from extension after washing out the uterus it was already too late.

Hr. Oskar Bentner, Geneva, gave material for a collective inquiry by 50 physicians as to whether operations should be dry or moist. No decisive distinction could be drawn. All the operators emphasised the necessity for peritonisation of the abdominal cavity. Thirty operated with gloves, 20 without, or only conditionally. For closing the wound catgut had the preference. For asepsis and in wounds of intestine the finest silk was used. Thirty operators only considered the following as indications for vaginal drainage: suspicious pus (in the abdomen), appendicitis, Wertheim's operation for carcinoma, septic peritonitis, intestinal complications, uncontrollable parenchymatous hæmorrhage, great loss of peritoneal surface, in the pelvis, suspicious ovarian tumours, vaginal total extirpation of the uterus. Strict asepsis, tender handling of the peritoneum, complete arrest of hæmorrhage were chief points for success.

Hr. Recasens, Madrid, said the vagina was the natural outlet for discharge from the pelvis, but that drains, whether of gauze or glass, rather prevented the union of wounds than provided for discharge. They should not be left in longer than 24 hours, except in exceptional cases.

AUSTRIA.

Vienna, Oct. 12th, 1912.

SYPHILIS.

THE International Congress for syphilis and dermatology had an interesting subject this year that led to a heated duel between French and Austrian authorities. Milian, of Paris, related the excellent results he had obtained from salvarsan therapy combined with mercury and iodide. He maintained that it caused an abortion of the syphilitic virus and reinfection and improved para-syphilitic conditions as well as leucoplacia tabes and the progressive paralysis, even curing recent tabes. His method of administering the drug was to give four intravenous injections every 5th or 6th day, increasing the dose from 0.3 to 0.6 of a gramme or 4 injections in 20 days; then a pause of 10 days, after which 8 injections of oleum cinereum and calomel in doses of 0.7 of a gramme, varying the latter with 8 injections of hydrarg. benzoatum in doses of 0.02—0.04 of a gramme, to which may be added an injection at first in the middle of the week of iodide of potassium gradually increased once a day to 3 grammes; finally a rest of 10 days and again 4 intravenous salvarsan injections given as above every 5th day.

Hallopeau recommended the use of heptine in doses of 0.02 of a gramme, while Gaucher affirmed he could not cure tabes or progressive paralysis, as Milian had

stated and thought his cases were chanciform papules. He is convinced that salvarsan is no better than mercury. Rosenthal is of opinion that mercury and salvarsan are effectual in the majority of cases and is in favour of the intravenous application. He believes that central nerve diseases are more common when salvarsan is given alone than when mercury is given in combination.

Nobl, of Vienna, said that his two years' experience of salvarsan treatment in 150 cases was quite abortive. Out of this number Wassermann's test was negative in most of the cases. With a combination of arsenobenzol and mercury the appearance of secondary phenomena was latent for a year.

Oppenheimer, of Vienna, recorded 160 abortive cases that he had treated, 39 with salvarsan and 22 with mercury. He had tried various ways combined with excision, but the best results he obtained was giving the salvarsan immediately after excision with energetic mercurial inunction. Finger (Vienna) said he did not know whether it was the temperament of the Austrian or his food and drink that gave different results than in France, but he found that a recurrence of nerve diseases was more frequent with salvarsan than with mercury, such as epileptiform and psychic symptoms, the result of arseno-intoxication. The fatality was more provoked by the arseno treatment as lues cerebri, tubercular meningitis and encephalitic hæmorrhage were more common by this treatment than with mercury. Again, it is not proved that the spirochæta is killed by a combination of mercury and salvarsan, on which would rely the success of the treatment. The reinfection after treatment with salvarsan is not free from objection as it has an unfortunate result of producing chanciform efflorescence. Its rapid action on the organism and frequent recrudescence of nerve diseases is a serious objection to its use and the doses administered should be small. In short he did not consider salvarsan as a substitute for mercury in the treatment of syphilis.

CANADA.

Toronto, Sept. 28th, 1912.

MEETING OF THE CANADIAN PUBLIC HEALTH ASSOCIATION IN TORONTO.

(Concluded from page 388.)

THE PERPETUATION OF AN IMPERIAL RACE.

Dr. CHAS. A. HODGETTS, of Ottawa, the President, delivered a very able address. He, too, was fully aware of the need for Canada to put her house in order from the public health point of view, and pointed out that upon every hand there was evidence that the people of Canada were following in the footsteps of the people of older nations by ignoring the simple laws of health. He said that physical degeneracy and all its attendant evils consequent upon such neglect, was to be found in the most recently settled portions of Canada, while physical defects and their attendant social evils were in evidence in the rising generation, even of Toronto. Dr. Hodgetts said that no empire could stand for long whose men and women were not virile and strong, and that it was to a consideration of how Canada could do its share in this the greatest task of Empire, the *perpetuating of an imperial race*, that the subject of public health was presented to the Association which represented the health interest of the Dominion of Canada. The speaker was especially severe upon town planning and housing generally in Canada. He said, in fact, that they had before them evidence that bad town planning and housing led inevitably to increased municipal expenditure, and therefore, higher taxes. It was known that under inefficient legislation, bad housing conditions grow up, and that owing to these evil environments, disease, crime, immorality and poverty resulting in physical degeneration are inevitably the issues. Yet in Canada they were planning houses by the hundred each year, building, rather it might be said, throwing together houses, and worse than all permitting a foreign element to live under worse conditions than would be permitted in their own country,

and there was no legislation in Canada which had a statesman of the calibre to propose a Bill which would adequately meet this alarming and awful situation. The gist of Dr. Hodgetts' address was that a Federal Health Department was necessary to properly cope with the situation. He drew attention to the fact that health was not only a matter for municipal consideration and action, but should also be dealt with by each national government. He showed that the medical inspection of immigrants was alone sufficient reason for the establishment of such a department, as the inspection now was inadequate and perfunctory. This was not the fault of the inspectors, but of the system. One or two medical inspectors were supposed to make an examination of several hundred persons often speaking a foreign language in a few hours. Dr. Hodgetts pointed out that a nation was like an insurance company, it accepted at a risk the life of each man, woman, and child passed as fit at the port of entry. Consequently the inspection should be adequate and thorough, and the result could best be brought about by the establishment of a National Health Department.

A HEALTH CONSCIENCE.

A feature of the meeting was the delivery of an address by Dr. W. A. Evans, for many years the able and energetic Commissioner of Public Health of Chicago. Dr. Evans is an orator as well as being an efficient administrator, and held the close attention of a large audience of men and women for two hours. The speaker in the course of his address said that it was difficult to give the valuation of a health department in dollars and cents. Some cities like Ottawa recently, did not value their health authorities until impelled by fear to do so during an epidemic. Cities had grown and prospered, because of their freedom from epidemics; others had suffered because they had been cursed by devastating plagues. Dr. Evans alluded to the thorough manner in which Cuba and Panama, two notorious pest holes, had been cleaned, and to the way in which outbreaks of disease might be eliminated in small places and a "health conscience" might be awakened. The province of a health department was to show the people their duty.

Another feature of the meeting was a section devoted to the consideration of social evils, presided over by Dr. Helen Macmurchy, herself an authority on such matters. This meeting was instructive as an object lesson on the intense interest now being evinced in social subjects by all sorts and conditions of men and women. In the discussions, business men, lawyers, dentists, nurses, ministers of all persuasions took part, and gave their views with regard to the best methods of preventing social misery.

The programme of the meeting was so full that it would be impossible to even consider briefly the various points dealt with. With respect to the

PURIFICATION OF WATER SUPPLIES,

and of Toronto water supply in particular, Dr. Bryce delivered himself of the opinion that as an old chemist he could not see how hypochlorite of lime was going to destroy the pathogenic germs in the sewage. To his way of thinking, it should not be called hypochlorite treatment but hypocrisy. Hypochlorite of lime is now used most extensively on this continent for purifying water and sewage. It does not appear to be regarded as an emergency treatment for water, but oftentimes as a routine treatment. In Toronto, for instance, it has been now used for a considerable time. It was said that when the filtration plant was completed its use would be discontinued. The filtration plant should be finished, and in fact as far as the contract is concerned is finished, but it has been found that it is not large enough, and an addition will have to be made. Thus it is likely that hypochlorite of lime will be employed until the filtration plant can supply all the water needed by Toronto for domestic purposes. The public and most medical men think that hypochlorite should only be used in emergencies, as it frequently gives an unpleasant taste to the water, but many American public health men appear to be of the

opinion that with its use the need for filtration is almost obviated. This is somewhat of a burning question at the present time.

In the section of

MILITARY HYGIENE,

Colonel G. Carleton Jones, P.A.M.C., Director-General Medical Service, Canada, read an excellent paper on the sanitation of a besieged city, and Major Lorne Drum read a paper on the Militia as a factor in public health.

Among other papers of note read were two on the prevention of tuberculosis by Drs. J. H. Elliott and G. D. Porter, of Toronto. At the closing session two important resolutions were passed. The first was to urge upon the Dominion Government the need for the establishment of a National Department of Health. The second was to the effect that a committee be appointed to draw up a memorial to be presented to the Dominion Parliament that it is against the interests of public health that raw sewage be permitted to discharge into waters which are used as the sources of water supply; that it is the conclusion of the Canadian Public Health Association that an Act regulating the pollution of streams is required in order to strengthen the hands of provincial authorities; that the Committee have power to draw up said memorial, and present to Parliament all available evidence and data bearing upon the prevention of the pollution of waters which are, or may be, used as sources of water supply.

Dr. J. W. S. McCullough, Chief Medical Officer of Ontario, was elected president, and Regina, Saskatchewan, was selected as the next place of meeting. The Executive Committee is as follows:—The President, the Secretary, Major Lorne Drum, Ottawa; the Treasurer, Dr. G. O. Porter, Toronto; Professor John Amyot, Toronto; Col. G. C. Jones, Ottawa; and Dr. C. A. Hodgetts, Ottawa. Just at the conclusion of the meeting the mournful announcement was made that Mrs. Starkey, wife of the first President of the Association, Dr. T. A. Starkey, Professor of Hygiene at McGill University, Montreal, had died somewhat suddenly. Most of the medical men present knew Dr. Starkey, appreciated his knowledge, and liked him for his social qualities, and for these reasons sympathised with him in his great loss. Some, like the writer, had known Mrs. Starkey, had partaken of her hospitality, and had fallen under the sway of her kind and lovable nature; these sympathised with Dr. Starkey more deeply by far. The Association passed a resolution conveying the sympathy of its members to Dr. Starkey. The city of Toronto gave the members of the Association a hearty welcome. Sir Edmund Osler gave an at-home in their honour, while Lieut.-Colonel and Mrs. E. Goodenham gave a musicale in their honour. The annual dinner was held at McConkey's Restaurant, when some eloquent speeches were made. Thus the meeting was a success from all standpoints.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

INAUGURAL ADDRESS BY PROFESSOR LORRAIN SMITH.

PROFESSOR LORRAIN SMITH formally entered on his duties on October 9th, by delivering his inaugural address to a large gathering of students and others in the M'Ewan Hall, Edinburgh. In introducing the new professor, Sir William Turner paid a tribute to the retiring incumbent of the chair. Professor Greenfield, after thirty years of active life in the University, had asked leave to retire. He had had double duties and double responsibilities, for not only had he taught pathology, but he had also acted as a clinical teacher in the Infirmary, and had discharged these duties with assiduity. It was evident that a new professor of pathology must devote himself wholly to that subject, hence, when the curators had to fill the chair they did not need to take into consideration the power of teaching clinical medicine, but had to look for someone

competent to teach pathology in the wide sense of the term, and they considered that they had found the right man. Professor Lorrain Smith had, as an arts student, gained one of the great prizes of the Scottish universities—a Ferguson scholarship. The subject was philosophy, so that he began to study medicine with a wide outlook. Soon he obtained the Professorship of Pathology in Queen's College, Belfast, and later in the University of Manchester, whence he came to them.

Professor Lorrain Smith, before beginning his address on the

PLACE OF PATHOLOGY IN THE MEDICAL CURRICULUM,

recalled the impressions made on him as a student by his old teacher, Professor Greenfield. In paying a personal tribute, he felt sure that his words were endorsed by the many pathologists in this country who were his pupils. The purpose of Professor Smith's address was to show the essential unity of pathology and medicine. He described the state of matters before 1831, when the chair which he now occupied was founded. Then pathology was taught by the physician, just as at a still earlier date physiology also had been. When once pathology had come to be recognised as a separate science it grew enormously—it grew in three directions, along histological, chemical and bacteriological lines. At present it was suggested in some quarters that histology had told us all its story, yet who could deny that the introduction of a new method might at any time lead to still further advance in this direction? Chemical pathology proceeded largely by experiment, and though from its great complexity progress was slow, it was opening up fresh avenues of knowledge daily. In its present state, the complaint was sometimes made that pathology was too remote from practical medicine. In order that it might come to its proper place he pleaded for a synthesis, bringing clinical medicine and pathology into closer touch. He concluded by showing that pathology only advanced by research. While he did not urge any special claim for pathology in comparison with other medical sciences as a field for research, the intimacy of the connection between it and clinical medicine made it easier for a man whose chief interest was practice to undertake research in pathology. Modern pathology was an experimental science, and anyone who desired to be really abreast of it must give himself to research.

INCLUSIVE FEES IN SCOTTISH UNIVERSITIES.

A conference of representatives of the General Councils of Edinburgh, Glasgow and Aberdeen Universities to discuss this question was held in Perth on October 5th. It was agreed to recommend inclusive fees in engineering and agriculture, in each case, of sixty guineas. After considerable discussion concerning the imposition of an inclusive fee in medicine the Conference agreed on the following resolution:—“That, having considered the memorandum of resolutions adopted at the conference of representatives of the University Courts of St. Andrews, Glasgow and Aberdeen on June 20th, 1912, and the report of the sub-committee of the General Council of the University of Glasgow, the conference finds that, while not opposed to the principle of an inclusive fee for University courses in medicine, further inquiry is necessary into the amount of the fee and into the form the regulations must take to protect the interests of the extramural schools.”

VITAL STATISTICS OF SCOTLAND.

In his report for the year 1910, just issued, Dr. J. C. Dunlop gives as the most noteworthy features of the vital statistics the lowness of all the principal rates—birth rate, marriage rate, death rate and infantile mortality rate are all below the average. The birth rate, 26.19 per 1,000 is the lowest yet recorded; the marriage rate, 6.52 per 1,000 is the seventh lowest; the death rate, 15.26 per 1,000 is again a record; while the infantile mortality rate, 108.3 per 1,000, though .6 above 1909, is unusually low. In all the years since 1855 there have only been three lower—1859, 1879 and 1909. The death rate from phthisis (115 per 100,000) continues to decrease; in 1860 and 1870 it was as high as

283, and until 1886 was constantly over 200. Among other diseases with lowered death rates are typhoid, whooping-cough, cerebro-spinal meningitis, pneumonia and bronchitis. Among high death rates are measles, scarlet fever and cancer. The last is now fully 25 per cent. higher than 10 years ago, 60 per cent. higher than 20 years ago and 100 per cent. higher than 30 years ago. How much of the increase is due to increased prevalence and how much to improved diagnosis, is doubtful. As regards the lowered birth rate, it is shown that until 1893 the birth rate was over 30; between 1894 and 1904 it ranged from 29.06 to 30.36; since 1905 it has steadily declined, being between 28 and 29 in the years 1905, 1906 and 1908, and between 27 and 28 in 1907 and 1909. The excess of births over deaths for the year amounts to 51,791, 2,210 less than the mean of the preceding 10 years. Legitimate children numbered 115,010, and illegitimate 9,049—a ratio of 7.29 per cent., which is practically the same as in 1909. For many years this percentage was a decreasing quantity, but during the last five years this has not been the case. From 1859 to 1873 it was constantly above 9; from 1874 to 1888 it varied between 8 and 9; from 1889 to 1897 it was between 7 and 8; from 1898 to 1907 it was below 7. Since then it has only twice been below 7, and thrice above it.

BELFAST.

THE SALARIES OF MEDICAL OFFICERS.—Several Boards of Guardians in Ulster have been discussing the question of graded salaries for their medical officers during the past week, among them being the Ballymoney, Clogher and Lurgan Boards. In most cases the matter is still under discussion. To the disinterested onlooker the discussions are often amusing, specially the wild statements made as to the "riches" of the medical officers, but to those involved there cannot be much joke. On the whole, however, there seems to be a more reasonable spirit in the Boards than was the case a little time ago, and the fact that the profession have combined in face of the Insurance Act is not without its moral effect. At Lurgan the local Government Board Inspector, Dr. O'Brien, attended the meeting and gave some interesting particulars as to the cost of medical relief. In Lurgan the cost of treating dispensary patients per 1,000 of the population was £14, in Ballymena £17, Newtownards £17, Lisburn £17, Banbridge £19 and Newry £23. It is a pity that the cost in a few towns outside Ulster was not added. The cost of each ticket issued varies from 1s. 8d. in Lurgan to 3s. 9d. in Lisburn and 4s. 1d. in Newry. Dr. O'Brien said that he thought the medical officers at Lurgan were justified in asking for an increase in salary, but after long discussion it was refused. One argument against an increase was that some time ago when there was a vacancy in Portadown dispensary, though only £80 was offered (the minimum proposed by the Committee being £100) four doctors applied for the post.

CARE OF CHILDREN'S TEETH.—The versatile Provost of Trinity College has appeared in a new rôle, as a popular lecturer on hygiene. Last week in the Orange Hall at Bushmills, Co. Antrim, he gave a lecture on the "Treatment of Children's Teeth," the chair being taken by Dr. David Huey, J.P. The Provost stated that to extend medical inspection of school children to Ireland, as carried out in England, would cost over £40,000 a year, and instead of this the Treasury had now doled out £7,500. At first it was only intended to use this money in the large towns, but he had got an important concession for rural districts, and if they formed committees, and formulated workable schemes and raised a local fund, they would receive an amount equal to that fund, to be added to it. An experiment had been instituted by Lord Gough in Galway, but unfortunately was stopped by the Land League. He suggested the formation of a committee and a local fund in Bushmills, and this having been approved of, subscriptions amounting to £30 from four local gentlemen were announced, which will no doubt be increased

by many smaller contributions. The further progress of the movement will be watched with interest.

MOTOR ACCIDENT.—Dr. R. A. Crawford, medical officer of Castlesbane dispensary district (Co. Monaghan) has sustained severe injuries by a fall from his motor bicycle, which collided with a dog. His injuries were attended to by Dr. J. Campbell Hall of Monaghan, and he is progressing satisfactorily.

MANCHESTER.

THE CHAIR OF OBSTETRICS AND GYNÆCOLOGY.

Professor Archibald Donald who has been appointed to the Chair of Obstetrics and Gynæcology left vacant by the death of the late Sir W. J. Sinclair, opened the winter session of his class on Friday, October 11th, with a short history of the chair of which he is the fourth incumbent. The first Professor of Midwifery and Diseases of Women in Manchester was John Thorburn, a man of wide knowledge and of broad sympathies, who founded the Southern Hospital for Women and Children, and who taught there and in the Owens College until his death in the year 1885. He was followed in the chair by Cullingworth, who only retained it until he went to London in 1888. Of him it might be said that he did more for gynæcology between 1885 and 1900 than any man in the country, with the single exception, perhaps, of Mr. Lawson Tait. When Cullingworth went to London (St. Thomas's Hospital) his views on pelvic infection for example were new and entirely heterodox, and it was only after persistence in the face of strong opposition that he lived to see them generally accepted. The third holder of this professorship was William Japp Sinclair, who occupied it from 1888 until he died on August 21st, 1912. Those who had only known him recently, when his powers were impaired by failing health, could have no idea of the intellectual force of his earlier work. The North of England Gynæcological Society and the Journal of Obstetrics and Gynæcology of the British Empire, both of which he founded, remained as memorials to his organising ability. The part he played in bringing about the amalgamation between the Southern Hospital and St. Mary's showed him capable of sacrificing personal considerations for the public good. The Southern, where he taught, was a small hospital; St. Mary's was a large institution, and its clinical material was largely wasted because it was not connected with the University. Sinclair favoured the amalgamation though it reduced him from being supreme in a small hospital to being one of several in a large one.

Perhaps Sinclair's main personal characteristic was his enthusiasm. He was a great fighter and keen in controversy, but he always fought for principles, never for personal aims. His advocacy of the Midwives Act, for example, made him many enemies and doubtless injured his practice. But he continued to advocate the training and education of midwives, and acted for several years as a member of the Central Midwives Board, while many who had opposed him came to see that his motives had been pure and his objects high throughout. He was aided in his battles by the gift of literary style. This often enabled him to bring opponents into sympathy with his aims even when they could not agree with his views. Sinclair was kindly and considerate to the poor, and his treatment was always designed with the intention of saving his patients pain. His private life was worthy of all esteem and socially his was a most attractive personality. The strenuous career he led was the one which suited him, and now he rests in peace.

PROBATE to the wills of two medical men was granted last week. In the case of the late Dr. Thomas Gardner, of Bournemouth, estate of the gross value of £13,994 was proved, of which £8,485 is net personality; Dr. Reginald E. Thomson, F.R.C.P., of Chelsea (retired), left estate of the gross value of £7,195, of which the net personality was sworn at £7,058.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE POSITION OF DENTISTRY.

To the Editor THE MEDICAL PRESS AND CIRCULAR.

SIR,—Recognising my position of detachment from general practice, you will not, perhaps, be surprised to learn that I am not a regular reader of medical journals, and have only to-day seen the copies of your excellent paper containing the articles and letters on "The Position of Dentistry." My old teacher, "A Hospital Dentist," who alludes to me in his letter to you on September 18th, has called my attention to this matter. My case is typical of many more. After a public school education, I began at 18 my dental and medical studies. I had a turn for mechanics. My advisers and I recognised that to be a good operator was the *sine qua non* of a successful dentist, and the time taken up in qualifying as a mechanic, a dentist, and a medical practitioner occupied quite seven years. At about 25 I was in a position to earn some money for myself, but looked too young for any position above an assistantship. After a few years in this position, I began practice in a small town. The inhabitants, including those around served by it, numbered about 30,000. There were already six qualified dentists in the place. I succeeded a recently deceased practitioner. Immediately on his death his two mechanics started in practice. I enclose samples of their advertisements and circulars. They are unqualified. As you see, they each state that they were so many years with the late Mr. ———, "surgeon dentist," and that they perform all the operations of dentistry, etc. They do not exactly style themselves "Dentist" or "Surgeon Dentist," the only thing the Act forbids, but they use language which makes even educated people take them for legally qualified practitioners. They circularise and tout for practice with great activity. I send also some sample advertisements from local papers of the three firms of travelling quacks who visit the town weekly or bi-weekly. They offer "American and English Dentistry," etc. They issue pamphlets freely by post throughout the neighbourhood. Such practices are impossible by any self-respecting qualified man, even if he were not prevented from adopting them by professional law and the General Medical Council. We have to compete with this unqualified practice, carried out, as you explain, under false pretences; and we have to endure the discomfort or odium of being ranked with these sordid tradesmen or unscrupulous quacks. It is bad for us; it is worse for the public. Of the latter fact I could give scores of illustrations; if you will allow me, I will end with two within my recent experience. A middle-aged lady is sent to me by a local doctor. She is suffering from chronic rheumatoid arthritis, suspected to be of septic origin. Examining her mouth, I find a large upper denture, a roughly made vulcanite frame holding six front and some back teeth. All the decayed roots are left beneath, and the plate is mainly held up by two silver pegs or pivots, which pass up the root canals of the canine teeth. These canals are full of putrid particles, and cannot be kept clean, whilst pus is oozing more or less freely from the alveoli of nearly all the other broken-down necrosed stumps. The lower front teeth are covered with a mass of foul tartar overlying the gum—a nest of septic putrefaction. Not the slightest attention had been given by the quacks to these conditions of disease; their aim, in which they succeeded, was to get a big fee—in this case it was £12—for a piece of work costing them a few shillings. It is, of course, more than probable that the broken health, and, consequently, shortened life of this patient may be ascribed to this malpractice. The second case is that of a girl of 12, taken by her mother to an "American" firm who, among other things, profess to "regulate children's teeth" by methods superior to those of other practitioners. This child had protrusion of the

upper incisors, due to a well-known malformation of the jaw. She was wearing a vulcanite frame covering all the back teeth, and having a wire across the faces of the incisors. It could have no effect whatever on the deformity. It kept the teeth constantly exposed to the acid decomposition of food *débris* under the plate, and all these teeth were badly affected with caries in consequence. In both these cases an action for damages for malpractice might be brought, but there is no one but myself to suggest it, and it would only need to be put by counsel to an enlightened jury, that a rival practitioner was the instigator, to make certain of a verdict, with costs, for the defendant.

I enclose my card; you will, I trust, agree that no obligation calls for the disclosure of my name, and I beg to subscribe myself,

Yours truly,

A COUNTRY DENTIST.

October 9th, 1912.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I was much interested in the reply that "A Hospital Dentist" makes to my letter published in your issue of the 25th September. Your correspondent does not make the position at all clear on the vital point at issue, namely, whether he merely wants an amending Act, whereby unqualified dental practitioners will not be able to use any description after their names which might mislead the public to imagine that they were qualified by examination, or whether on the other hand he wants an Act absolutely prohibiting the practice by unqualified men. By his remark, in which he seeks to draw an analogy from the legal profession, to the effect that "it is absolutely impossible for an unqualified man . . . to practise as a solicitor under any pretence of any kind," it would seem that he is aiming at total prohibition; but by the preceding sentence, where he refers to the Dental Acts being specially designed to enable the public to distinguish between legally qualified and unqualified practitioners, it would seem that he is simply aiming at a defining Act. Now a gentleman who seeks to champion the cause of his profession in an important medical paper, should have clear ideas on the subject on which he writes before endeavouring to instruct other people. Let me at once say that there are few, if any, respectable unregistered dentists who would resist a legal designation defining their position *vis-a-vis* to the qualified men. If on the other hand it is thought to prevent the unregistered men from practising altogether, I say again it is crying for the moon.

Your correspondent does not attempt to answer my contention that the number and the charges made (and necessarily made) by qualified men render them unable to supply the dental needs of the poorer classes of the community. The poorer classes of the community, however, are the large majority of the British nation. Your correspondent, "A Hospital Dentist," may imagine that he is living in the mid-Victorian period, but this is the 20th century, and he and those for whom he writes will have to answer to Parliament the simple question as to how they propose to supply the dental needs of this vast class of the community at present supplied by the 25,000 *bona fide* but unregistered practitioners. There is only one way out that I can see, and that is a State Dental Service on a gigantic scale, which to the extent of 80 or 90 per cent. would have to be supported by the tax-paying and rate-paying classes. Which alternative does he advocate? Like the hero in melodrama, I pause for a reply.

I am, Sir, Yours truly,
AN INTERESTED OBSERVER.

GAS FIRES AND VENTILATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is very important that gas fires should only be used in sitting-rooms and bedrooms when it is clearly proved that there is an up draught in the chimney, so as to carry off the poisonous vapours generated by the combustion of gas.

A few weeks ago my daughter went to see a friend in rooms just off the Strand, where the heating was entirely supplied by gas fires. As she had to wait some time she lit the fire, and sat down to read. When the friend arrived my daughter was found lying unconscious in the arm-chair, and for some hours there was much anxiety in restoring her breathing and circulation. I have devoted a great deal of attention to the question of the ventilation of gas fires, and have no hesitation in saying that the *Daily Telegraph*, in its recent article on "The Domestic Economy of Coal Gas," is not correct in stating that "medical testimony has disposed of the old objection that a gas-fire contaminates the air. . . ."

I am, Sir, yours truly,
R. L.

OBITUARY.

DR. R. LAING, OF BLYTH.

By the death last week of Dr. Robert Laing, the town of Blyth has been deprived of its oldest medical practitioner and one of its most worthy citizens. The deceased, who was 68 years of age, was the son of the late John and Mary Laing, formerly of Jesmond. He studied at the University of Durham, receiving no less than seven medals in various subjects. In 1869, he became L.R.C.P. and L.M.Edin., and M.R.C.S.Eng. He took the D.P.H.Camb. in 1889. Dr. Laing was the Medical Officer of Health for the Cowper Urban District until, a few years ago, that authority was amalgamated with the Blyth Council. He was a county justice for Northumberland, and as such was a regular occupant of the Blyth Bench. He was formerly Prosector of Anatomy at the Newcastle-upon-Tyne College of Medicine, and he was a medical inspector under the Factory Act, in addition to being Surgeon to the Cowper Coal Company.

DR. F. H. LOW.

We regret to announce the death of Dr. Frank Harrison Low, of 13 Wimpole Street, W., which took place on the 8th inst, after a few days' illness, at his residence, Heath Bank, Blackheath Rise, at the age of 58. The deceased, who qualified as L.S.A. in 1875, became M.B., C.M.Aberd. and M.R.C.S.Eng. in 1876, studying at King's College, London, and the University of Aberdeen. He was well known as a medical radiographer, being Medical Officer to the X-ray Department at the London Medical Graduates' College and Polyclinic, having previously occupied a similar post at King's College Hospital and at the Paddington Green Childrens' Hospital. Dr. Low was Honorary Secretary of the Roentgen Society, and he was a Vice-President of the West London Medico-Chirurgical Society. He had formerly held appointments in Hammersmith as Medical Officer to the Homes for the Aged Poor and Divisional Surgeon to the Metropolitan Police.

MEDICAL NEWS IN BRIEF.

The Irish Local Government Board and the Sanatorium Benefit.

On behalf of the Local Government Board, Mr. E. Bourke, member of the Board; Dr. E. Coey Biggar, Medical Inspector; and Mr. C. H. O'Connor, General Inspector for Dublin, received a deputation of the Dublin Joint Committee charged with the administration of Insurance Act Sanatorium Benefits, when representations were made as to the L.G.B.'s prevention of "home" sanatorium treatment in cases where tuberculosis patients could not be sent to sanatoria.

The Joint Committee have been administering "home" treatment since last July through the Samaritan Committee of the Women's National Health and other philanthropic organisations con-

sidered to classify as "institutions" for the purpose of the Act. The L.G.B. now refuses to recognise this procedure, although the Insurance Commissioners declined to decide the point.

Question of Funds.—Admitting that the domiciliary treatment would be useless without food, etc., the L.G.B. representatives said it was doubtful that the Act empowered this, and, even if it did, they feared the funds available would not be sufficient. They advised the Committee to send a few urgent and most desirable cases only for treatment to sanatoria, as they admitted that, if all the cases attended by the Committee were sent the cost would be much greater than under the present system.

The Committee asked that the present procedure be allowed temporarily until March 15th next, when they would be in a position to see how the cost worked out and how the funds would be affected.

This request is to be formally submitted by the Committee to the Board for consideration.

The deputation consisted of—Her Excellency the Countess of Aberdeen, Ald. Dr. M. Walter, Councillor Wm. McCarthy, Dr. Rowlette, and Miss Gargan.

The Hospital Saturday Fund.

THE annual metropolitan collection under the auspices of the Hospital Saturday Fund was made on Saturday last throughout London. Since 1897 the street collections have been abandoned, and the collections have been made in boxes distributed in banks, business houses, and shops during the fortnight ending on Hospital Saturday. Special help was given this year by the theatres and picture palaces, collection boxes being displayed in the vestibules and in other cases being carried round among the audiences during the performances. Several railway companies arranged for collections on the station premises.

The total amount paid into the fund through the various committees and the general fund in 1911 was £45,468, but Mr. Davis, the Secretary, stated last week that it was expected that the amount would this year be less owing to the Insurance Act. Up to midsummer the income was nearly £600 greater than that for the corresponding period last year, but the July, August, and September returns showed the loss of this lead of £600 and an additional loss of £200. This period corresponds with the beginning of the operations of the Insurance Act, and Mr. Davis said it was noticeable that the penny weekly subscriptions on the cards of many factories and workshops began to fall off directly the contribution cards of the Insurance Act were in use.

The Rebuilding of the Chelsea Hospital for Women.

THE Council of the Chelsea Hospital for Women, Fulham Road, are appealing for funds to rebuild the institution. The present space is altogether inadequate, so that there is a long waiting list and the want of sleep from which patients suffer after their operations makes removal from the noise of the motor traffic urgent.

Lord Cadogan has presented the Council with a site for rebuilding the hospital in a quiet street near by; the trustees of the Zunz Bequest have promised £10,000; and it is reported that the chairman of the hospital, Mr. T. Dyer Edwardes, is willing to forego his mortgage of £4,000 on the present building and freehold site so that they may be sold unencumbered; but a sum of £30,000 is still required. A dinner in aid of the funds will be held on November 20th at the Savoy Hotel, at which the President, Lord Castle-reaugh, and his sister, Lady Ilchester, who is President of the Ladies' Committee, will jointly preside. The Queen has contributed £21. Lady Esher has collected £500, Mrs. Hugh Fenton £200, the Prudential Assurance Company 50 guineas, and the London County and Westminster Bank £20.

Further donations will be received by the Hon. Acting Secretary, Mr. S. Hoffnung-Goldsmid, or by the Secretary, Mr. Herbert H. Jennings, at the Hospital, Fulham Road, S.W.

Peamount Sanatorium, co. Dublin—Action for Injunction.

It is stated that a number of owners of the lands adjoining those on which the proposed Peamount Sanatorium is situate are taking steps with a view to asking for an injunction in the Chancery Division to restrain the trustees from using the premises as a Sanatorium for persons suffering from tuberculosis. The defendants named are her Excellency the Countess of Aberdeen, the Right Hon. Sir David Harrel, Right Hon. L. A. Waldron, Right Hon. M. F. Cox, and Mr. William M. Murphy. It is stated also that unexpected difficulties have arisen as to the water supply of Peamount, and that the Local Government Board has refused to sanction further expenditure until they are satisfied that a water supply is secure.

Royal College of Surgeons of England—New Diplomates.

At a meeting of the Council of the College on Thursday last, the following candidates, having passed the required examinations, were admitted members of the college: Narayan K. Bal, Bombay Univ. and Middlesex Hosp.; Crawford C. Marshall, Melbourne Univ. and Middlesex Hosp.; Jivraj N. Mehta, Bombay Univ. and London Hosp.; John Saner, Cambridge Univ. and Guy's Hosp.; William C. Toll, Toronto Univ. and Middlesex Hosp.; John Ward, Manchester Univ. and Middlesex Hosp.

Arthur L. Robinson, M.B.Lond., M.R.C.S. L.R.C.P., of Liverpool Univ. and University College Hosp., was admitted a Fellow of the College.

The following candidates, having fulfilled the requirements of the dental and surgical sections of the Board of Examiners in Dental Surgery, were admitted Licentiates: Oswald G. Aylen, Birmingham Univ.; Gilbert J. S. Rose, Middlesex and National Dental Hosp. and George L. Venning, Middlesex and National Dental Hosp.

London Hospital Medical College.

In connection with the London Hospital Medical College the following scholarships have been awarded for the winter and summer session 1911-12:—

Price Scholarship in Science (£100), Mr. R. G. Simpson; Price University Scholarship in Anatomy and Physiology (£52 10s.), Mr. W. D. Newcomb, of Trinity College, Cambridge, and Mr. A. C. Ainsley, of Caius College, Cambridge, æq., scholarship divided; Entrance Science Scholarship (£50), Mr. V. J. F. Lack; Epsom Scholarship (£126), Mr. S. H. de G. Pritchard; Buxton Scholarship in Arts (£31 10s.), Mr. H. L. Douglas and Mr. S. E. Harvey, æq., scholarship divided.

Royal Academy of Medicine in Ireland.

THE annual meeting of the Academy was held last Friday. The report stated that during the past year the number of Fellows was 169, Members 27, and Associates 3. The total attendances at the meetings were 656, which is considerably less than the number (817) reported last year. The accounts have been audited, and show a balance to credit of the Academy of £261 2s. 8d. At the request of the University of Dublin the Academy was represented at the Bicentenary Celebration of the School of Physic, and an address of congratulation was presented; and in connection with this occasion a number of Honorary Fellows were elected by a special meeting of the Academy. The Council reports the loss to the Academy through death of the Rt. Hon. Lord Lister, F.R.S., Sir Thornley Stoker, Bart., M.D., F.R.C.S., David Baldwin Jacob, M.D., F.R.C.S., Robert John Montgomery, M.A., M.B., F.R.C.S.

The elections of officers and Councils resulted as follows:—

President: Walter G. Smith.

General Secretary: J. Alfred Scott.

Secretary for Foreign Correspondence: Sir John Moore.

Medical Section.—President: J. F. O'Carroll; Council: James Craig, H. C. Drury, J. A. Matson,

Sir J. Moore, T. G. Moorhead, G. Peacocke, F. C. Purser, E. J. Watson, and W. A. Winter.

Surgical Section.—President: R. D. Purefoy, P.R.C.S.; Council: C. A. Ball, Alex. Playney, L. G. Gunn, W. S. Haughton, W. Pearson, Seton Pringle, R. A. Stoney, E. H. Taylor, W. I. de C. Wheeler, and R. H. Woods.

Obstetrical Section.—President: A. J. Horne; Council: Gibbon FitzGibbon, M. Gibson, A. N. Holmes, F. W. Kidd, T. Neill, R. D. Purefoy, J. Spencer Sheill, Alfred Smith, B. A. Solomons, and E. H. Tweedy.

Pathological Section.—President: A. H. White; Council: A. H. Benson, William Boxwell, L. G. Gunn, W. G. Harvey, E. J. McWeeney, T. G. Moorhead, T. T. O'Farrell, W. D. O'Kelly, R. J. Rowlette, and A. E. Wynne.

Section of Anatomy and Physiology.—President: B. J. Collingwood; Council: A. F. Dixon, A. C. Geddes, T. P. C. Kirkpatrick, A. A. McConnell, and E. J. McLoughlin.

Section of State Medicine.—President: M. J. Nolan; Council: A. E. Boyd, W. M. Crofton, W. R. Dawson, T. P. C. Kirkpatrick, J. A. Matson, and W. A.

annuance was a prize in money (£5) and a silver medal as a memorial to the late Dr. Savill will be awarded in July, 1913 and yearly to the student (of either sex) at the West End Hospital for Nervous Diseases, who shall make the best *viva-voce* examination in diseases of the nervous system, in addition to writing a thesis on a subject approved by the examiners. All students (qualified or unqualified) who have attended at the hospital not less than 25 times are eligible. A triennial lecture will also be given, to be called "The Savill Lecture," at the Hospital referred to.

University of Oxford.

In a Congregation held on October 10th, the following degrees were conferred:—M.Ch., H. S. Souttar, Queen's; B.M., N. S. Lucas, New College.

Bequest to the Bethlem Royal Hospital.

THE late Mr. Joshua Vardy, of Portsmouth, formerly surgeon to the Royal Portsmouth Hospital, whose will was proven last week, left estate of the value of £22,236. He bequeathed £1,000 to the Bethlem Royal Hospital "as a thankoffering in recognition of the very kind treatment and care bestowed upon my brother, the late Samuel Provis Vardy, during his long stay there," and directing that this sum should be used by the governors of that institution as they in their sole discretion may think fit, "in furtherance of this noble institution." He also bequeathed £50 to the Royal Portsmouth Hospital, and the remainder of his property for equal division between thirty cousins and second cousins.

Edinburgh University—Public Health Diplomates.

THE following candidates, having passed the requisite examinations of the Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Royal Faculty of Physicians and Surgeons of Glasgow, in October, were last week admitted Diplomates in Public Health:—Edward L. Middleton, Alexandra B. MacCallum, John D. Ingram, John C. MacCallum, Dewan Jai Chand, William G. Macdonald, Jane H. M'Iroy, George C. Strathairn, Daniel C. Adam, Alexander J. Ewing, George V. T. M'Michael, and Peter Allan.

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistantcies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

CONTRIBUTORS are kindly requested to send their

...wants, 20 cestodes, and 10 trematodes.

Dr. F. P. (London).—We are of the opinion that metal scrapers and wire mats are preferable to fibre mats for school purposes, or, indeed, for the main entrances of any public building.

CARBOLIC ACID A SECTION 5 POISON.

It is stated upon reliable authority that the Privy Council will shortly place liquid preparations of carbolic acid and its homologues containing not more than 3 per cent. of these substances within the category of those governed by Section 5 of the Poisons and Pharmacy Act, 1908. In other words, they will be required to be sold retail in vessels distinguishable by touch, labelled "Poisonous—not to be taken," and bear the name and address of the seller in the same way as mineral acids and caustic alkalis.

Mr. S. HOPE (Purley).—One of the latest springs possessing the property of radio-activity is the ancient hotwells spring at Clifton, the water of which has been recently stated to contain an amount of radium emanation equal to an activity of 0.93 milligrams of radium in 1,000,000 litres.

Meetings of the Societies, Lecturs, &c.

WEDNESDAY, OCTOBER 16TH.

ROYAL MICROSCOPICAL SOCIETY (King's College, Strand, W.C.).—8 p.m. to 11 p.m.: Conversazione.

THURSDAY, OCTOBER 17TH.

ROYAL SOCIETY OF MEDICINE (DERMATOLOGICAL SECTION) (1 Wimpole Street, W.).—5 p.m.: Cases by Dr. Walsh, Mr. McDonagh.

CHILD STUDY SOCIETY, LONDON (Royal Sanitary Institute, 90 Buckingham Palace Road, S.W.).—7.30 p.m.: Dr. T. P. Nunn: Psychological Development of the School Subjects.

FRIDAY, OCTOBER 18TH.

ROYAL SOCIETY OF MEDICINE (OTOLOGICAL SECTION) (1 Wimpole Street, W.).—5 p.m.: Dr. Dundas Grant: Presidential Address—Otolological Discussions: Matter and Method. Cases and Specimens by Mr. R. Lake, Arthur Cheate, Dr. Dan McKenzie, Dr. W. Milligan, Mr. Macleod Yearsley and others.

ROYAL SOCIETY OF MEDICINE (ELECTRO-THERAPEUTICAL SECTION) (1 Wimpole Street, W.).—8.30 p.m.: Introductory Address by the President, Dr. R. Morton.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE (11 Chandos Street, Cavendish Square, W.).—8.30 p.m.: Report Resignation by Dr. W. Carnegie Brown of his Post as Joint Secretary of the Society, and move a Resolution thereon.—The President (Sir William Leishman): The Etiology of Blackwater Fever (followed by a Discussion).

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5 p.m.: Prof. Keith: Demonstration on Specimens Recently Added to the Collection of the College Museum.

Appointments.

CUMBERBATCH, E. P., M.B., B.Ch.Oxon., M.R.C.P., Medical Officer in Charge of the Electrical Department at St. Bartholomew's Hospital.

ELMSLE, R. C., M.S.Lond., F.R.C.S.Eng., Orthopaedic Surgeon to St. Bartholomew's Hospital.

FENWICK, D. E., M.B., Ch.B., House Physician at the Hampstead General and North-West London Hospital.

HILL, ISABEL, M.B., Ch.B.Edin., Medical Officer for Women and Children at the Workhouse Infirmary, Darlington.

IRWIN, S. T., M.B., M.Ch.Belf., F.R.C.S.Edin., Assistant Surgeon to the Children's Department at the Ulster Hospital for Children and Women, and Assistant to the Professor of Surgery at the Queen's University, Belfast.

McKERRON, ROBERT GORDON, M.D.Aberd., Regius Professor of Midwifery in the University of Aberdeen.

WATSHAM, HUGH, M.D.Cantab., Medical Officer in Charge of the X-Ray Department at St. Bartholomew's Hospital.

Vacancies.

Corporation of Birmingham Fever Hospital.—Medical Superintendent. Salary £250 per annum, with board, etc. Applications to Medical Officer, Council House, Birmingham.

Surrey County Asylum, Netherne, Merstham.—Third Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

Bradford Royal Infirmary.—House Physician. Salary £100 per annum, with board, residence, and washing. Applications to J. J. Barron, Secretary-Superintendent.

Burton-on-Trent Infirmary.—House Surgeon. Salary £120 per annum, with furnished rooms, board, coal and light free. Applications to the Secretary, Mr. John Wood, The Infirmary, Burton-on-Trent.

Birkenhead Borough Hospital.—Senior House Surgeon. Salary £100 per annum, with board and laundry. Applications to the Secretary.

St. Mary's Hospital, London, W.—Junior Casualty House Surgeon. Salary £100 per annum, with board, and lodging. Applications to Thomas Ryan, Secretary.

Drumcondra Hospital, Dublin.—Ophthalmic Surgeon. Applications to the Registrar before October 26th. (See advt.)

Births.

BLACK.—On Oct. 10th, at Warrington Lodge, Warrington Crescent, London, the wife of Dr. Norman Black, of Singapore, of twin sons.

BRIGGS.—On Oct. 6th, at Grasmere, Hayesfield Park, Bath, the wife of Dr. Seymour Briggs, of a daughter.

BROWN.—On Oct. 10th, at "Perrymead," Streatham, S.W., the wife of Dr. Thos. H. Brown, of a daughter.

CAMPBELL.—On Oct. 8th, at The Copse, Larbert, Stirlingshire, the wife of Robert B. Campbell, M.D., M.R.C.P., of a son.

HOSKYN.—On Oct. 10th, at 69 Clifton Road, Rugby, the wife of Charles Reginald Hoskyn, M.B., B.S.Lond., of a son.

SINCLAIR.—On Oct. 8th, the wife of Dr. H. W. Sinclair, of a daughter.

TAYLOR.—On Oct. 7th, at 8 Melville Street, Edinburgh, the wife of Dr. Macrae Taylor, of a son.

Marriages.

FLOWERDEW—MACKWORTH.—On Oct. 4th, at Bombay Cathedral, Richard Edward Flowerdeew, Captain Indian Medical Service, ninth son of Mr. and Mrs. Arthur J. Flowerdeew, of Billingford Hall, Scole, Norfolk, to Caroline Jane, youngest daughter of the late Mr. and Mrs. Horace E. Mackworth, Bucksburn, Aberdeenshire, and granddaughter of the late Col. Sir Digby Mackworth, Bt., Glen Uske, Monmouthshire.

GASKELL—EADEN.—On Oct. 10th, at Little Shelford, Cambs., John Foster Gaskell, M.D., son of W. H. Gaskell, M.D., F.R.S., The Uplands, Great Shelford, to Margaret, daughter of John Frederick Eaden, of Little Shelford.

ILOTT—SATTERTHWAITE.—On Oct. 12th, at the Parish Church, Bromley, Kent, Dr. Cyril Herbert Thomas Ilott, only son of Dr. Herbert J. Ilott, of Bromley, to Lucy Annette, eldest daughter of Col. E. Satterthwaite, C.B., and Mrs. Satterthwaite, of Bromley, Kent.

JOHNSTONE—MACASSEY.—On Oct. 5th, at St. Stephen's Church, Dublin, William Montagu Lucas Johnstone, M.B., High House, Newent, Glos., son of R. H. Johnstone, D.L., of Bawnboy House, Co. Cavan, to Evalyne Clara Livingstone, daughter of the late L. L. Macassey, M.Inst.C.E., and of Mrs. Macassey, 5 Wilton Place, Dublin.

ROOKE—MOORE.—On Oct. 8th, at the Parish Church, Chipping Barnet, Alfred Basil Rooke, F.R.C.S., of Bournemouth, youngest son of the late Alfred Bradley Rooke, and of Mrs. Rooke, of North Finchley, to Stella, youngest daughter to Mr. and Mrs. Edgar Richardson Moore, of Chipping Barnet.

TURNER—ELGOOD.—On Oct. 9th, at St. Paul's Church, Avenue Road, N.W., Alfred Charles Turner, of St. Philip's Place, Birmingham, son of Charles Turner, of Hatch End, Middlesex, to Olive Muriel Elgood, M.B., M.S.Lond., youngest daughter of G. J. Elgood, J.P., of Aberdeen House, Adelaide Road, N.W.

Deaths.

DEWES FOWLER.—On Oct. 11th, at 12 Crescent Mansions, Notting Hill, Ursula Mary Dewes Fowler, M.D., daughter of the late Rev. Alfred Dewes, D.D., Vicar of St. Augustine's, Pendlebury.

EPPS.—On Oct. 13th, at Wellgirth Road, North End, Hampstead, Washington Epps, M.R.C.S., L.R.C.P., youngest son of the late Dr. George N. Epps, aged 64.

GIBB.—On Oct. 9th, at Peking, James Glenny Gibb, aged 34 years, elder son of the late Dr. James Glenny Gibb, who died last week, and grandson of the late James Gibb, of 51 Ladbroke Grove, London, W.

LOW.—On Oct. 8th, at his residence, Heath Bank, Blackheath Rise, S.E., after a few days' illness, Frank Harrison Low, M.B., of 13 Wimpole Street, W., aged 58.

WROUGHTON.—On Oct. 9th, at Cardros, Scotland, William Charles Haultain Wroughton, L.R.C.P., M.R.C.S., late of Carlisle.

NOTES AND COMMENTS.

The Nobel Prize.

THE recent presentation of the Nobel prize to Dr. Alexis Carrell serves as a timely reminder of the great strides surgery has made in recent years with regard to the vascular system.

Hearts can be sutured, slit or punctured blood-vessels sewn up by ligaturing a portion of their wall without blocking their lumen, cut vessels sutured end-to-end, arterio-venous anastomoses carried out in gangrene, portions of blood-vessels transplanted, and so on. Some of these wonders, it is true, have been demonstrated only upon the lower animals, but there is no reason to doubt that they can all be applied to man. That a great advance has been made thereby it is impossible to doubt. The treatment of aneurysm and of some kinds of atheroma, especially in the local form of the latter, may become amenable to the art of the surgeon. The *technique* of operative procedures upon the blood-vessels is necessarily of a difficult and delicate nature. One interesting feature is that the asepsis which suffices for abdominal operations falls short of the standard required for the successful suturing of blood-vessels. Even where union has been apparently ideal, there has been some lurking asepsis sufficient to block the lumen of the vessel.

Dr. Carrell's Field of Conquest.

DR. CARRELL, however, has pushed his discoveries to various practical applications that bid fair to have results of a kind that, if seriously mooted a few years back in the pages of a medical journal, would have suggested doubts as to the editorial sanity. Who would have believed it possible that a kidney could be taken out of one cat and transplanted into another, and that the latter would not only recover from the operation, but go on living contentedly with the aid of the substituted kidney? Yet that has been done by Dr. Carrell. The obvious inference is that one day diseased kidneys in man will be taken out and replaced by kidneys of the sheep or other animal, possibly of the monkey, which is next of kin to the genus *homo*. Could Baron Munchausen have imagined a prettier tale in his happiest vein of inspiration? But the matter does not end there; if one organ can be thus handled, why not another? Dr. Carrell may perhaps one day provide us with some direct surgery upon the valves of the heart. If a wounded heart can be stitched up and the patient recover, why should he not equally be able to withstand a deliberately inflicted surgical wound? Of a truth, it seems not remotely impossible that within the lifetime of the present generation we may hope to see the surgery of the valves of the heart placed on a sound footing as a recognised everyday operation.

Punishments that do not fit the Crime.

THE Report of the Prisons Commissioners may well give rise to misgivings in the mind of the thoughtful philanthropist. What is this "crime" for the commission of which we brand so many of our fellow-countrymen with the stigma of a degrading punishment? In the year 1911 no less than 128,539 persons were committed to prison for periods varying from a few days to a month. In a great number of cases they were sent to gaol in default of payment of a small money fine, a fact that emphasises the stupid folly of the proceeding. For a trifling offence a man who happens not to be able to command a few half-crowns wherewith to purge his crime is sent to prison. As a result, he probably loses his situation, and may not get another, while his wife and family may become chargeable to the Poor-law. The bargain for society is stupid in the extreme. Far better to spend money in feeding the destitute than a hundred times the amount in keeping them and theirs in prisons and workhouses. It would be far cheaper to the taxpayers to supply needy country folk with game bought at the poulterers than to pay for the support of all the persons directly and indirectly thrown upon the public funds as the result of offences against the Game Acts!

Quis Custodiet Ipsos Custodes?

IT is the chief duty, as we understand it, of the respective Local Government Boards of the three countries, to regulate and control the activities of the various local authorities. The Local Government Board for Ireland, like its sister boards, checks the extravagances of the local bodies, restricts their activities within legal limits, and occasionally stimulates them to the fulfilment of their statutory duties. Moreover, one of its greatest powers is that of surcharge for expenditure wrongfully incurred. However shy the Board may be to apply pressure for the promotion of the public health, it is never slow to exert its authority to surcharge. Unfortunately, there is no higher power which can surcharge the members of the Local Government Board, when, through neglect or ignorance, they squander the public funds. If there were, it would take several years' salary from the members of the Board to make good the sums lavished recently on the Peamount Folly. The Women's National Health Association, by the means of public funds, advanced from time to time on the authority of the Local Government Board, has erected a huge "sanatorium" at Peamount, on the borders of the counties Dublin and Kildare. When the institution was about to be opened for patients it was discovered that the question of a water supply had been overlooked. The nearest water suitable for drinking purposes is a well some two miles away, whence

all water has to be conveyed by cart! We cannot for the moment recall any more scandalous instance of a Government Department playing fatuous ducks and drakes with public money.

LEADING ARTICLES.

THE MEDICAL ASPECTS OF THE GREAT WAR IN THE NEAR EAST.

AFTER an interval of comparative rest the problem known as the Eastern question has reasserted itself with more than wonted vehemence. Four kingdoms, namely, Bulgaria, Servia, Montenegro and Greece, have allied themselves in what bids fair to become a final struggle against the yoke of Mohammedan Turkey. The last-named country, fresh from a war with Italy, now finds herself faced with armed defiance from surrounding nations who have been under her suzerainty. It will be generally conceded that the position of Turkey has been brought upon herself by the cruelty and injustice of her government. She is now surrounded by armies that far outnumber her own, but the fighting qualities of the Turk render it unsafe to predict the issue of the fierce war which has now begun. Whether or not the great European powers will permit the fight to go on to the end it is equally impossible to foretell. As a medical journal, however, we are able to speak with confidence on certain aspects of the affair which touch the inner philanthropy of nations all the world over. The conduct of a war in which no less than five armies are concerned must necessarily entail a great loss of life and great sufferings to the sick and wounded. As a matter of fact, it is generally understood that the revolting nations are none of them properly supplied with a fully equipped and adequate army medical corps. Indeed, in the case of first-rate European powers it has always invariably been necessary to supplement the army medical arm by the aid of voluntary red-cross organisations. In the case of Turkey, Greece and the Balkan nations the need for special help in that direction is peculiarly great. Owing to the remoteness of the scene of conflict, to the mountainous nature of much of the ground to be traversed, to the uncouth and even semi-barbarous ways of some of the combatants, to their little-known language, and to other racial and religious factors, the task of rendering them aid is beset with unusual difficulties. Happily it is not the way with our countrymen to discuss details of that kind when lives are at stake. Already the British Red Cross Society has dispatched one well-equipped expedition to Montenegro under three surgeons. During the present week three complete units are being sent out to Turkey, each one consisting of three surgeons, three dressers and twelve orderlies. In addition three directors are being sent to the North Balkan States, Turkey and Greece respectively, their official duty being to look after the Red Cross interests in each area. Clearly, this provision barely touches the fringe of the actual require-

ments of the war. It is gratifying, therefore, to find that an English newspaper, the *Daily News and Leader*, has once again come to the rescue, and with noble enthusiasm is raising a fund in aid of the sick and wounded. As might be expected, the appeal for help has met with a prompt and generous response. An enterprise of this kind is costly, but there is little doubt that the fine previous records of British journalism in this direction will be maintained, if not surpassed. The approach of winter will render the campaign extremely arduous. Well may it remind us of the history of the sufferings of our own soldiers in the terrible Crimean campaign. Some of the fighting in the present outbreak has taken place round Scutari, a name that will ever be associated with our own history as the site of the hospital to which our sick and wounded were sent in the later stages of the war. Meanwhile, at any moment great pitched battles may be fought, and it is terrible to think what human sufferings may ensue owing to the want of adequate medical care and attention. Experience has shown that skilled medical men are always forthcoming in sufficient numbers, and all that remains is for a generous nation to provide the funds for which the *Daily News* is pleading with a kindly enthusiasm that must alike confirm its friends and disarm its opponents. The thing to think of for the moment is the picture of wounded and sick soldiers lying untended on bivouac and battlefield, and of what may be done to lessen the sufferings thus begotten of war—that great surviving link between reasoning man and his unreasoning brutish ancestor. Medical science—fair offspring of reason and humanity—is best fitted to assuage and mitigate the evils thus begotten of international hatred. Fortunately, the best modern skill of the surgeon and the physician is in this case available.

THE FRIENDLY SOCIETIES AND THE PUBLIC IN IRELAND.

IT is curious how apathetic the English public has remained in regard to the failure of the authorities to make terms with the medical profession for the working of the medical benefits of the National Insurance Act. The bullying tactics of the Chancellor of the Exchequer and some of his supporters, and the no less vulgar misrepresentations of some of the party journals, have alike failed to rouse any resentment against the profession for standing out for satisfactory conditions of service. The man in the street sees that it is a matter of business between the doctor and those who wish to employ him, and he stands aside to allow the bargaining to proceed undisturbed. In Ireland there is as yet no dispute between the authorities and the profession. The clauses relating to the medical benefit do not apply to Ireland, and there is no reason, either in the nature of things or in the finances of the Act, why the sanatorium benefit cannot be amicably worked. It is true that the Chairman of the National Insurance Com-

mission, with singular impatience and with ignorance, not only of the demands of the profession, but of the terms of the Act it is his duty to administer, has attempted to create a feeling of irritation in the profession, and to mislead and excite the public, but it is to be hoped that his foolishness will not seriously impede arrangements, which, prior to his outbursts, were proceeding satisfactorily. In Ireland, however, there is a serious enough question at issue between the friendly societies and the profession, though it is not incapable as yet of friendly adjustment. The enormous increase of friendly societies, their sudden encroachment on the domain of private practice, and the fact that they are now State-aided, render it necessary that society work should no longer be regarded by the doctor as an exercise of his private charity. The contract between the medical officer and the friendly society must in future be a strict matter of business, fair remuneration being the return for adequate services. Recognising these facts, the medical profession in Dublin, Belfast, and elsewhere, has given due notice to the societies of the terms on which, after January 1st, 1913, members of the profession will be willing to accept society work. The friendly societies are, no doubt, seriously considering the problem, and very naturally have formed a union through which alone negotiations with the medical profession are to be conducted. This is quite right and business-like, for organisation on one side is as desirable as on the other. The friendly societies' union, however, is apparently not confident of being itself able to conduct the business for which it has been established, for it is now attempting to rouse the public against what is described as "the cupidity of the doctors." It is announced that a public meeting is to be held at an early date, in the Mansion House, Dublin, for the purpose of protesting against the unreasonable demands of the medical profession on friendly societies, and that the Lord Mayor has consented to preside, should he be in Dublin at the date of the meeting. The calling in of the public to help in the settlement of a business matter seems to us a weakness on the part of the officials of the societies. They must hope to get by intimidation what they despair of winning by reason and fair dealing. It can only, however, have the effect of embittering the dispute and of strengthening the spirit of the medical men concerned. We regret to note that the Lord Mayor of Dublin has permitted himself to take sides in this dispute between two important bodies of the citizens. Mr. Sherlock, since coming to the chief dignity of the city, has hitherto show a praiseworthy liberality of conduct, and a judicious consideration of the rights of every class of the citizens. It is the more regrettable that he should now throw the weight of his personality and position with either side in what is essentially a business dispute. Not content with attempting to rouse public opinion in a general way, some of the friendly society officials

have succeeded in persuading the poor law guardians of the North Dublin Union to adopt the absurd measures embodied in a resolution we quote in another column. *Inter alia* it is proposed to stop the supply of bodies to the medical schools. In order, as they think, to injure the medical profession, the guardians are willing to put a stop to medical education in Dublin, and inflict an irreparable injury on the city itself and on the whole country. It may be necessary to point out that it is in the interests of the public, and not primarily of the profession, that the medical men of the future should be thoroughly grounded in the essentials of their art. Again, were the resolution of the guardians to prove effective in limiting educational opportunities in Dublin, the rate-payers would be the sufferers by the loss of the schools of medicine. Lastly, if the number of men entering the profession were really curtailed, the power of those already in practice would be increased. We have no fear, however, of any of these things. The folly of the resolution is so obvious that it is bound to be rescinded without loss of time. We repeat that the difference between the doctors and the societies is a business matter to be settled between the parties concerned. The intervention of any third party can only be an obstacle to a settlement.

CURRENT TOPICS.

Bettering the Race.

NOWADAYS, when we are all practical meliorists, the problem of the improvement of the race as a whole is always being presented to us in some form or another. The study of heredity and the teaching of active and passive eugenics with the practice of tentative reforms in the matter of environment and nutrition assail the question in all quarters from the most ultimate fundamentals to the merest superficialities. These problems of nature and nurture are attacked with characteristic thoroughness and enthusiasm in America. American public opinion resembles that of Athens in the respect it gives to any new thing. Originality is actually an advantage, and an idea *per se* is not taboo. In the United Kingdom we have, it is true, had proposals for the sterilisation of the unfit brought before us, and vasectomy has been seriously suggested as a means of lessening the offspring of the philogenitive paranoiac. At a meeting of the Georgia Medical Society we are referred to men who have performed castration almost wholesale on the inmates of institutions for the feeble-minded, with results entirely satisfactory to the operators, who claim that disciplinary measures are useless, that vasectomy leaves the patient in possession of the very essence of his disordered state and that segregation is economically unsound, as it offers no opportunity for the defective subject's return to a more or less useful career as a citizen without the danger of his perpetuating his kind. Whatever our opinions may be, it is certain that the

legislative conscience of this country will not sanction such schemes at any rate for some considerable period.

Electrically Sterilised Milk.

THE *Boston Medical and Surgical Journal* prints an account of some interesting experiments conducted by Dr. C. B. Novoy and Professor J. C. Caldwell at the Ohio State University at Columbus on the electrolytic purification of milk. Their method is to allow the milk to flow through a series of metal vessels which form electrodes of opposite polarity, while an alternating current of 2.5 amperes at a pressure of 2,000 volts is applied for fifteen seconds. Their results were extraordinary. Milk, containing over 19 million bacteria per cubic centimetre, had this number reduced by 99.97 per cent., and several other similar experiments gave results of the same magnitude. The milk showed no chemical changes that would account for the sterilisation, nor was the heating that took place sufficient for this purpose. It would seem that further investigation on these lines might lead to a method of value in the production of the all-important pure milk. The method apparently has the advantage that it might be applied equally readily to large or small quantities of milk. Moreover, if applied on a large scale, it ought to be the most economical method of producing safe milk. As no chemical changes are found to occur in the milk as the result of the electrolysis, its nutritive value and æsthetic properties remain unchanged. It will be necessary, of course, to ensure that it is not specially the pathogenic bacteria, such as the tubercle bacilli, which are unaffected.

Industrial Diseases.

AN official intimation has been issued making known the fact that the Industrial Diseases Committee has resumed its labours. The Committee consists of Sir T. Clifford Allbutt, His Honour Judge A. H. Rugg, K.C., Dr. T. Morison Legge, Medical Inspector of Factories, with Mr. Ellis Griffiths, K.C., M.P., of the Home Office, as Chairman. Evidence has been taken within the last week or two with regard to the occurrence of Dupuytren's Contraction among minders of lace machines. The Committee will later inquire whether there is any evidence of the occurrence of this disease in other trades. In the Workmen's Compensation Act of 1906 six diseases are scheduled. Several others were added in 1907 and 1908. The question now being considered is whether to schedule Dupuytren's Contraction, cowpox, and clonic spasm of the eyelids apart from nystagmus, so as to enable workmen disabled by these diseases to claim compensation if the disease is due to the nature of their employment. Any of our readers desiring to give evidence for or against the extension of the Workmen's Compensation Act to these diseases should communicate with the secretary of the Committee at the Home Office. It seems hardly necessary to point out that if the Committee should feel able to formulate definite opinions upon the questions at issue a vast amount of costly and tedious litigation may be prevented.

The Medical Society and Dr. Lettson.

Few persons, even among those who know London fairly well, are aware that in Bolt Court off Fleet Street, midway between Fetter Lane and Farrington Street, there still exists the house in which Dr. J. Coakley Lettson lived and practised and in which he settled the Medical Society of London in the year 1787. In Bolt Court, too, and contemporary with Lettson lived Samuel Johnson. His house was pulled down and on its site has been erected a School of Photo-engraving and Lithography by the County Council. In a recently-published account of "Fleet Street in Seven Centuries," Mr. Walter G. Bell writes:—"Nothing of note is left of Bolt Court save No. 3. This picturesque, eighteenth-century building is quite unspoilt. It was the residence of Dr. John Coakley Lettson, who in 1787 settled the Medical Society of London there. In 1790 he gave the house, which was his freehold, to the council; his other benefactions to the Society, of which he was a founder in 1773, and three times president, included funds and a library of books. The Society remained there until 1850, and one of the treasured possessions at their present premises in Chandos Street, Cavendish Square, is a painting by Medley of a meeting of the council in Bolt Court, at which Dr. Lettson, a tall spare figure, is presenting the title deeds. The canvas contains twenty-two portraits of medical men." It is interesting to recall that Medley was the maternal grandfather of the late Sir Henry Thompson, eminent alike as a painter and surgeon. Mr. Bell adds: "The Medical Society of London has enrolled in its ranks all the distinguished physicians in the capital for upwards of a century, and honours the memory of its most illustrious founder by the Lettsonian Lectures delivered in its theatre. It still owns the old house in Bolt Court. Over the entrance is the Society's emblematic tablet, placed there by Lettson himself. A ribbon bears the name. The central figure, standing in front of a pyramid, is the Isis of Sais, the revealer of the secrets of Nature, who presided over medicine; having discovered the virtues of healing plants, she is said to have invented it. The Sphinx and the coiled serpent on either side of her represent Eternity. Within the circle beneath is an inscription in worn Greek capitals, which translated reads: 'I am whatever is, or has been, or will be, and no mortal has hitherto drawn aside my veil.'"

The Holborn Baby Show.

THE success which attended the holding of the Baby Show the other day at the offices of the Holborn Borough Council argues well for the multiplication of such exhibitions in other populous districts. Sixty of the best babies in Holborn, most carefully chosen from 250 candidates up for examination and competition, ranging in age from one month to a year old and are the children of parishioners of Holborn, flower sellers, stage supers, tailoresses, charwomen, etc. They were examined by Drs. Florence E. Willey and E. Bolton, and the special points to be taken into consideration were: age, size, weight, general fitness, cleanliness, etc. All the babies were fed naturally with the exception of ten who were brought up on cow's milk. The prizes, which took the form of useful baby

clothes, were presented to the winners by the Mayoress of Holborn, and further dignity was lent to the scene by the presence of the Mayor. The purpose of the Baby Show was to demonstrate the value of the work done by the municipality of Holborn in reducing the death rate of Holborn. This can be expressed in figures as follows showing the death rate per thousand in Holborn in 1911 and six preceding years:—

1905	1906	1907	1908	1909	1910	1911
126	128	131	111	101	100	113

(The infant death rate in the whole of London, year 1911, being 129). The slight increase for the year 1911 is accounted for by exceptionally hot weather, there having been 26 deaths from diarrhoeal diseases in comparison with only nine in 1910. The whole of this work is under the direction of the Medical Officer of Health for Holborn. A very large proportion of the good done is owing to the supply of prepared milk at special rates so that any mother may have milk for her baby for the low price of 4d. a day. Those who are unable to pay anything have the milk given to them free and this is rendered possible by the generosity and public spirit of the Mayor, Mr. Hazell, who himself makes up the deficit every year. It is to be hoped that the good example of such a public-spirited municipality may be followed in other great centres.

An Experiment in Public Medical Service.

At a meeting of the governors of the Salisbury and South Wilts Provident Dispensary last week the medical staff put forth a scheme for further medical service for persons who would not be insured under the new Act. The small revolution involved is, it seems, being carried out with the friendly co-operation of the committee. The medical staff have resigned, and the work of the dispensary will come to an end in January. It being not yet known what arrangements may be made by the county insurance committee, the scheme does not at present deal with insured persons. The staff offer to rent the dispensary, and it is possible the rent may be devoted to the fund for supplying special treatment. The wage limit has been fixed at £2 per week. For uninsured persons the insurance will be 2d. a week if the income exceeds £1 a week, and 1½d. if it does not exceed £1. A tariff has been arranged for the inclusion of wives and children. The conditions of the service embody all the claims of the British Medical Association; and the scheme will be run on business lines.

PERSONAL.

SIR DONALD MACALISTER was among the recipients last week of the honorary degree of D.Sc. of the University of Bristol.

DR. H. VALENTINE MCKENZIE, M.D., C.M. Edin., has been appointed Honorary Ophthalmic Surgeon to the Newton Abbot Hospital, Devon.

PROFESSOR WALTER G. SMITH, M.D., has been elected President of the Royal Academy of Medicine in Ireland for the ensuing year.

DR. B. A. H. SOLOMONS and Mr. R. H. F. Taffe have been admitted to the membership of the Royal College of Physicians of Ireland.

DR. J. A. BRAXTON HICKS, M.D., B.S. Lond., D.P.H., has been appointed Pathologist and Registrar to the Queen Charlotte's Lying-in Hospital.

The honorary degree of Doctor has been conferred on Dr. Sydney Young, Professor of Chemistry in the University of Dublin, ex-Bristol University.

SIR GEORGE H. SAVAGE, M.D., delivered the Presidential address last night before the newly constituted Section of Psychiatry of the Royal Society of Medicine.

DR. JOHN NEWPORT LANGLEY, Professor of Physiology at the University of Cambridge, has been awarded the Retzius Gold Medal of the Swedish Medical Society.

DR. J. EDWARD SQUIRE, C.B., delivered an interesting lecture last week in connection with the Tuberculosis, Nursing and Cookery Exhibition held at Gloucester.

MR. EDMUND OWEN, LL.D., F.R.C.S., Consulting Surgeon to St. Mary's Hospital, has been elected a Vice-President of the Royal College of Surgeons of England, in the place of the late Mr. Clinton T. Dent.

DR. J. A. D. RADCLIFFE, Pathologist to the King Edward VII. Sanatorium, was presented last week with the Weber-Parkes Medal of the Royal College of Physicians of London in recognition of his work on tuberculosis.

DR. DUNDAS GRANT will deliver the inaugural lecture of the winter session at the Central London Throat and Ear Hospital on Friday, October 25th, at 3 p.m., on "Some Views in Oto-Rhino-Laryngology Reviewed; Some Criticisms Criticised."

MR. HUBERT DUNBAR SHEPHERD, of Kedleston Road, Derby, M.B., F.R.C.S., Medical Officer of the Derbyshire Sick Children's Hospital, President Royal Medical Society, Edinburgh, who died on August 12th, left estate valued at £3,070 gross, with net personalty £2,812.

DR. G. H. W. ROBERTSON, J.P., has been awarded the Medal of the Order of St. John of Jerusalem in England for his heroic conduct in attending to the wounded passengers in a railway accident in South Africa last year, while he himself was seriously injured and suffering great pain.

ALDERMAN DR. YOUNG, of Bolton, has resigned his appointment as a member of the Bolton Insurance Committee on the ground that he cannot consistently occupy the position and at the same time remain loyal to his brethren of the medical profession during the present strained relations with the Government.

MR. LEONARD ARTHUR BIDWELL, F.R.C.S., aged 47 years, of 15 Upper Wimpole Street, W., and of Tower House, Bexhill, Surgeon-Major in the Bucks Yeomanry, Consulting Surgeon to the City Dispensary and the Blackheath and Charlton Cottage Hospital, left estate of the gross value of £12,223, of which the net personalty has been sworn at £8,305.

PROFESSOR METCHNIKOFF, of the Pasteur Institute, Paris, will deliver the Lady Priestley lecture on "The Warfare against Tubercle" in London on Friday, November 20th, at 4.30, in the great lecture theatre of the Royal Society of Medicine, 1, Wimpole-street, Cavendish-square. It will be given in French and illustrated by lantern pictures. Professor Metchnikoff is delivering the lecture under the auspices of the National Health Society, of which Princess Christian is president. Members of the society will be admitted on presentation of members' tickets. Applications for tickets for non-members, price 10s. 6d., must be made before November 20th, to the secretary, National Health Society, 53, Berners-street, Oxford-street, W.

A CLINICAL LECTURE

ON

TWO CASES OF ACROMEGALY. (a)

By T. GILLMAN MOORHEAD, M.D., F.R.C.P.I., D.P.H.,

Visiting Physician to the Royal City of Dublin Hospital.

SINCE its first recognition as a definite clinical entity some twenty-five years ago, acromegaly has continued to exert a curious fascination on the medical mind, a fascination more than justified by the strange transformation that the disease produces in the features and forms of those unfortunate individuals who are victims of the malady. Long before the time when Pierre Marie in 1886 achieved fame by his description of two cases of this as yet unknown disease, isolated cases had been recorded under different names, and one may well imagine that the occurrence of such cases could in a superstitious age give food for many a fable in which a witch's curse came true.

To us, however, to-day, not the history of acromegaly in sculpture, in folklore, or in medical writings is the most important, but rather the practical recognition and diagnosis of the condition as we are likely to encounter it in practice. It is commonly believed that acromegaly is a disease so rare that it is almost unnecessary for the medical student to take cognisance of it, but the very fact that I am able to show you two cases to-day and the further statement that I have seen at least three other cases, one of them in Vienna, the other two in Ireland, is sufficient to disprove such a belief and to justify me in selecting the subject for our consideration this morning.

In Sternberg's classical work on the subject it is pointed out that in attempting to arrive at a diagnosis of the cause of any particular group of symptoms, unpleasant mistakes may occur if the golden rule is omitted in every examination of a patient to review the whole individual, at least in a hasty manner. So important is this golden rule that one might regard it as one of the primary axioms of medical diagnosis, but as it is apt to be neglected in these days of minute examination, I recall it before introducing the patients. As you view the features of both of them you will realise that anyone with sight behind his eyes could diagnose the affection, as my old teacher, the late Dr. Bennett used to say, from the saddle of a high trotting horse, yet one of the two had apparently gone unrecognised for years, though under medical care for many of the subjective phenomena characteristic of acromegaly.

The first of the two patients is an example of the benign form of the disease, which may last apparently indefinitely, and is accompanied by only trifling disorders. She is a woman aged 65, who has been under my observation for the last eight years. She first came to my extern department in the autumn of 1904, and then presented a most striking appearance. She was most intensely cyanosed, her breathing was stridorous and her general aspect that of an individual in imminent danger of death. With difficulty she stumbled across the floor of the room, and sank into a chair unable to do more than concentrate her attention on a further effort to gain respiratory ease. A rapid examination revealed the cause of

her trouble in the presence of a cystic polypus attached by a pedicle above the left vocal cord, and impacted in the rima glottidis. At each inspiration the impaction became more pronounced, while during expiration a little relief was obtained. My colleague, Mr. Stoney, removed the polypus without difficulty, and time was then obtained for a study of the other peculiarities which the patient presented, and which I now demonstrate to you. During the eight years that have elapsed since I first saw her little or no change has taken place in her appearance, as can be proved by a comparison of photographs taken after her first visit with her appearance now. The first thing to attract attention is the extreme redundancy of the soft tissues

PHOTO OF CASE I. (For description see text.)

of the face: the lips are very full, the *alæ nasi* much enlarged, and the cheeks and forehead puffy. The skin is moist and greasy, of a brownish tinge, and the hair is coarse. The head is massive, enlarged in an antero-posterior direction, and presenting high and prominent temporal ridges, which have receded as the temporal muscles have gradually crept upwards on the side of the calvarium. There are no teeth, but the lower jaw is much enlarged, and on inspection of the interior of the mouth the tongue is seen to be enormous with huge circumvallate papillæ. The rima glottidis is also very big and the cartilages of the larynx are prominent. The next feature to attract attention is the hand; its enlargement is proved by the fact that the patient wears a ring which is now quite irremovable and is, indeed, almost embedded in the substance of the finger. The term "battledore hand" well describes this peculiarity. A similar enlargement of the feet is present, and the X-ray pictures which I show you demonstrate that the enlargement is due not only to bony overgrowth, but also to general hypertrophy of the connective tissues of the extremities. It is often stated that the enlargement of limbs in acromegaly is entirely confined to

(a) Delivered at the Royal City of Dublin Hospital.

the hands and feet, and that no enlargement of the legs or arms is met with, and that in this way the disease can be distinguished from hypertrophic pulmonary osteoarthropathy in which the enlargement usually involves the entire limb. This is, however, only true in part; undoubtedly the enlargement of the hands and feet is out of proportion to that of the arms and legs respectively, but a glance at this patient's limbs will, I think, convince you that they are thicker and more massive throughout than one would expect to meet even in a strong working woman. In other ways this patient also conforms to the typical acromegalic type; she presents, as you see, a marked kyphosis of the dorsal spine, and the antero-posterior diameter of her chest is much increased, the whole thorax being typically anthropoid in type. An interesting symptom is extreme brown pigmentation of the skin of the entire body. This condition is described as occasionally met with, but it must be rare to find it so universal and so pronounced. The appearance, in fact, is that of rough tanned leather.

As regards subjective symptoms, it is most important to note that this patient does not complain in any way. Dr. Leonard Mark, himself an acromegalic, who recently published a profoundly interesting account of his personal experiences, complains that most text-books of medicine, while crammed with detail concerning the various physical changes that may be noted in the disease, are for the most part silent concerning those symptoms, which are all-important to the patient. In his own case, serious faceache, headache, nasal catarrh, ocular troubles, and a frequently recurring state of apathetic yet troubled drowsiness, to which he applies the term "the acromegalic state," pursued him, and to some extent still pursue, throughout the entire course of his disease. Fortunately, however, many cases, even when there is distinct enlargement of the pituitary body, as the enlarged sella turcica in the X-ray photograph proves to be present in this patient, run a benign course, and suffer in no way, except, perhaps, in their vanity. This patient's cerebral development is not of the highest order, and so it has been difficult positively to exclude the existence of all ocular symptoms, but certainly no subjective troubles of importance have attracted attention since the laryngeal polypus of which she at first complained was removed.

Of very different type is my next patient. He belongs in Sternberg's classification to the "commonest form, chronic acromegaly, the duration of which is from eight to thirty years." I first saw him in August, 1908, when, as he walked into my study, the diagnosis was written on his face. He was then about thirty years of age, and his change of appearance as compared with a photograph of ten years previously was so great that it was difficult to believe that the photograph was of the same individual. With the physical aspect of this patient I need not detain you, as in general he presents the same characteristics as the previous patient. One notices the enlarged cranium, the sloping forehead, the prominent lips, the big mandible, the huge tongue, and the enlargement of the hands and chest. The feet in this case are apparently not altered, and the patient himself says that he now wears the same size boots as he did fifteen years ago. Further, there is no pigmentation of the skin. Many subjective symptoms, however, are present. For many years he has suffered from severe headaches; in fact, he will tell you that he is never for a single day entirely free from pain, and that sometimes the headache is almost intolerable. He has had a good deal of ocular trouble, having severe astigmatism in both eyes, and, in addition, a careful examination of his

visual fields shows a well-marked bitemporal hemianopsia. This symptom, which is produced by pressure on the optic chiasma, is practically diagnostic of acromegaly, and is of course produced by the changes in the pituitary fossa and the base of the skull. Loss of memory and extreme somnolence are complained of; fatigue is easily produced by comparatively slight exertion, and occasionally palpitation proves troublesome. In neither of the two cases is there any abnormality of the blood or urine.

Having now demonstrated to you the main features of these cases, we may proceed to discuss briefly some of the important questions for which an answer is so urgently required in our attempt to understand the physiological processes at work, and in our attempt to alleviate or cure these unfortunate cases. Here, as elsewhere in the domain of physiology and pathology, clinical medicine has led the way and has marked out the paths along which laboratory research may with most hope be conducted. In the original memoirs of Pierre Marie one case is recorded in which the pituitary gland was enlarged, and even prior to this, Langer, in his study of the skeleton of giants, had noted the existence of an enlarged sella turcica in one variety of giants. The association of changes in the pituitary gland with the syndrome of acromegaly is now a long established fact, and much work has been done to endeavour to discover the function of the pituitary gland and the part it plays in the production of disease.

In 1908, Paulesco, by a series of well-planned operations on dogs, proved fairly conclusively that the presence of the pituitary gland is absolutely essential to life, and was of opinion that removal of the anterior glandular lobe alone was equivalent to removal of the entire gland, and was uniformly fatal. Removal of the posterior lobe led, he found, to no appreciable disturbance whatever. As these conclusions have been in the main confirmed by Cushing and his collaborators, we may, despite the fact that Horsley has obtained quite different results after operations on monkeys, for the present accept that the pituitary gland is essential to the maintenance of life. The train of symptoms produced by its removal are, according to Cushing, quite characteristic, and consist in a peculiar form of paresis, more especially of the hinder part of the body, muscular tremors, subnormal temperature, gradually increasing lethargy and death. Cushing, however, found that the posterior lobe of the gland was by no means functionless, and definitely concluded that it furnishes a secretion which acts in an opposite way to the internal secretion of the pancreas, and, in fact, diminishes the power possessed by the tissues of metabolising carbohydrates. If this be so, an interesting sidelight is thrown on one of the symptoms of acromegaly. It has long been known that in certain stages, more particularly the early ones of acromegaly, glycosuria may be present, and that such glycosuria is likely to disappear in later stages. Interpreting these facts with the aid of Cushing's results, it would naturally seem that the earlier process in acromegaly is one of hyperfunction of the pituitary, and that later on, as a result of progressive changes in the gland, diminished function results.

Many other interesting facts have been made known by experiment, a few of which are worth recalling. One of the occasional symptoms of acromegaly is extreme polyuria, a symptom which was present for some time in the second of the two cases that we have seen, and the explanation of this occurrence seems to be found in the fact that injection of extracts of the posterior lobe have a powerful diuretic effect. The diuretic effect is, in

fact, so pronounced that it is stated by some to be the most powerful diuretic drug that we possess.

The rise of blood pressure produced by injections of pituitary extract is now well recognised, as are also the stimulating effects produced on peristalsis and uterine contractions, but as these up to the present have no recognisable connection with acromegaly, it is unnecessary to dwell upon them.

Feeding experiments have given various results. Schäfer, in a preliminary report, finds that feeding with the anterior lobe causes increased rate of growth in rats, while Sandre, with similar experiments, recorded arrest of growth. Again, continued injection of extracts of the anterior lobe has been found quite devoid of result, while injections of the posterior lobe over a prolonged period led to wasting and degenerative changes in the liver and spleen.

When, from these few results that I have quoted out of the many records so admirably summarised in Swale Vincent's recent work on "The Ductless Gland," we endeavour to arrive at a conclusion as to whether we are dealing in acromegaly with hyperfunction or hypofunction of the pituitary, a definite answer is obviously impossible. A majority of the facts is, however, in favour of hyperfunction. The most usual enlargement in the disease is adenomatous in nature; polyuria and glycosuria are, as already pointed out, occasional symptoms, and, lastly, hypofunction of the reproductive organs, a condition almost universally present in acromegaly, is believed to be an actual cause of pituitary hypertrophy.

There remains for discussion differential diagnosis, treatment and prognosis. None of these, however, need detain us long. As far as differential diagnosis is concerned, my own feeling is that once the idea of acromegaly has entered one's mind in connection with a case, little difficulty should be experienced in excluding other possibilities. Sternberg gives a formidable list of no fewer than thirty-four distinct conditions which may be or have been mistaken for acromegaly; and no doubt mistakes occur, and at times legitimate doubt may exist regarding a diagnosis. It is therefore worth while remembering that an X-ray photograph of the skull will almost certainly show an enlarged sella turcica in acromegaly, and that amenorrhœa in women and loss of sexual power in men are usual early symptoms.

Prognosis has to some extent been already considered, inasmuch as we have already recognised the existence of a "benign type" and of an "ordinary type" of the disease. A few very acute cases have occurred in which sarcoma of the pituitary body was present, but in most cases it is safe to expect many years of life. Further, the sufferer in an "ordinary case" may be cheered by telling him that frequently in the later years of the malady the headache and other painful symptoms become less. At the same time, indeed, the memory may become worse and the mental powers may greatly deteriorate; but this information may be judiciously concealed, and, indeed, it occasionally happens that even in mental condition these patients improve in the later stages.

Our knowledge of its pathology and clinical course does not hold out much hope that medical treatment is likely to be very successful in curing the disease. A large number of remedies have been tried, more especially glandular extracts, testicular, thyroid, and pituitary gland itself. If the cause of the disease is hypertrophy of the pituitary gland, administration of the pituitary extract might at first sight seem contra-indicated. This is, however, not necessarily the case. It is now well recognised that thyroid extract is a most useful

remedy in causing subsidence of parenchymatous goitres, the actual theory underlying the method of treatment being that the goitre is the result of a demand on the part of the body for more thyroid secretion, and that if this is supplied from outside sources the thyroid will return to its normal size. Arguing in a similar way, it might be supposed that pituitary extract would lead to a diminution in size of an hypertrophied pituitary gland. Be this as it may, I can confidently report a considerable improvement in the subjective symptoms of the second case after a three months' course of pituitary gland tabloids, though there was no objective evidence of improvement. So strongly does this patient believe in them that he has again and again voluntarily returned to their use, while, on the contrary, he has formed the opinion that thyroid extract is quite useless. This experience is different from that of Magnus Levy, who has reported a case in which pituitary extract seemed harmful. One must, of course, accept statements of patients with becoming scepticism, but I am at any rate convinced that the pituitary has not done this patient any harm, and its subjective result in the case would lead me to prescribe it again. When speaking of his condition before and after its use, the patient, who is an educated man, is emphatic that it was beneficial.

If, however, medical treatment be put on one side, we must next enquire what surgery can offer. There is an increasing record of successful cases in which the pituitary gland has been removed, and apparently in acromegals the entire removal of the gland does not of itself prove fatal. The operation is, however, most serious, and should never be undertaken except at the urgent request of a patient to whom the full course of the disease has been explained and who is fully aware of the gravity of the surgical procedure. A mere decompression operation is, of course, less serious, and may be beneficial in relieving headache. Finally let me add that no matter what view one takes regarding the prospect of cure by either medical or surgical means, no slackness should be shown in attempting to relieve symptoms. Local treatment may benefit nasal catarrh; suitable glasses may be prescribed; and relief may often be obtained for the headache or faceache by means of the ordinary analgesic drugs. It may be necessary to change one's drug frequently as the one in use loses its effect, but we should never weary as the patient pins his faith on his medical adviser, and if he is met with the statement that nothing can be done he is likely to drift into the slough of despond. Hope deferred, remember, is better than despair.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by G. Hoppe-Seyler, M.D., Professor of Medicine in the University of Kiel. Subject: "The Treatment of Icterus."

A Health Conference at the Guildhall.

At the Guildhall, on the 28th inst. and two following days, a conference on "The Health of the City Worker," arranged by the Incorporated Institute of Hygiene, will be held. The Lord Mayor is to receive the delegates on the first day. On the 28th Sir William Bennett will preside, and the subject discussed will be "The Health of the Business Man." On the 29th, under Professor Haliburton's presidency, "The Health of the Warehouseman and Clerk" will be dealt with, and on the 30th, when Sir Thomas Oliver takes the chair, "The Health of the Factory Worker" will be under discussion.

ORIGINAL PAPERS.

THE PASSING OF MORBID ANATOMY. (a)

By SIR JAMES FREDERIC GOODHART,
LL.D., M.D., F.R.C.P.,

Consulting Physician, Guy's Hospital.

AFTER referring to the far-reaching character of the immortal discovery of William Harvey, the orator went on to emphasise the importance and, indeed, the fundamental necessity of studying the life-history of the living cell, and especially of the individual cancer cell. Much important work had been and was being done by Dr. Bashford and his fellow-workers of the Imperial Cancer Research Fund, for during the last ten years this subject had been followed up in short-lived animals, such as the mouse, where alone it was possible, and the results seemed to show, not that the environment, but that the individual cell was the master of the situation, and that the dominant issue which came up was—What was there in that cell or influencing it that gave to it such an inexhaustible power of propagation?

But were they sufficiently alive to the fact that pathology was no series of stationary phenomena, but constantly on the move, like all else in Nature? What alterations had they not seen in 40 years? Pyæmia might be said to be wiped out; typhus was well-nigh forgotten; typhoid fever had altered; diphtheria seldom attained the initial severity that so often characterised it of yore and was much more amenable to attack; scarlatina was of a much milder type; erysipelas was more of a rarity; malaria and Malta fever had been run to earth; the late results of syphilis seemed to him to be far less often in evidence; lardaceous disease, so very common in their early days, was now seen but seldom; and they had come at grips with acute rheumatism, and, it was to be hoped, with tuberculosis. Probably as much might be said of other diseases, and good old age was both more prevalent and more enjoyable. It was true that those ills belonged to the great group of epiphytic diseases that had been abolished in direct response to the researches of Pasteur and Lister, and that there was no such evidence of any general move all along the line. But if they made away with even one large group of maladies, how large a part of the morbid anatomy of the organs must alter too, and even then how little account would be taken of numberless arrested purposes that made for the beginnings of other diseases. Pathology not only changed but it shifted its ground. He was told that morbid anatomy was now much less in evidence, and discussions of the intricate problems that were behind it occupied more attention. We had not yet reached finality. Even bacteria were probably results and not causes; they strove with or cancelled one another to ulterior ends, and we were gliding on in advance of the most painstaking morbid anatomy. How like was radium in all but death to what he would call the aureole of life! Here was one substance that was always spending yet was never spent; that had power within it to regather of its loss, and by its action on the cell might even be said to originate the function of vitality. But did the spirit of life die? It might correlate with other forces of Nature; it might perhaps transfer itself to other forms of being. Had we begun to see that it might transcend the firmament of space? The physician thought not

of death but of the tenacity of life, and of how long, save by catastrophe, it took to bring the machine to a standstill.

THE TREND OF MODERN PATHOLOGY.

All the changes and shifting of ground suggested to him the existence of a struggle on the part of the pathologist to find out some morbid change for every disease. But now the time had come when it seemed worth while to insist that all this work upon the foundations had, unconsciously perhaps, been ushering in a new point of view, and the latest phase of pathology concerned itself with the investigation of function. It was now no longer so much the morbid change as the prejudicial function that was to be their quarry, or rather the passage of the one into the other. He was there to contend that the future of pathology would be a physiological one, the study of erratic function that had confirmed itself into an habitually baneful one. And he saw no reason for limiting the pathology thus engendered to function only. It was surely permissible to hold that morbid function might bring about structural change. There was not an organ of the body of which this was not true, but how largely and obviously so when applied to the brain. A large part of the structural disease of the brain was led up to by slow and insidious misapplications of thought and action that ultimately declared themselves as pronounced disease. Insanity thus became a cancer-like mood of the cells of thought, as well as a mood of growth.

Another instance might well be fatigue, for it was a disease nowadays. They all knew the machine that would not spark aright. There was nothing to be called structural change, and even rest furnished no remedy. It was clear that what was required was a fresh stock of some form of energy for charging up the machine that they were as yet not able to supply—so far away, and yet perhaps so nigh. And with fatigue might well be coupled pain, for there were those who almost seemed to be born in pain and of a sort that no remedy was able to assuage. Even more than death, pain was our hereditary foe; no quarter was given. In olden days hysteria stalked abroad, but to-day a broader view of physiology would teach that pain was no certain indication of any existing morbid anatomy; that its intensity was always subjective, individual, aloof from standardisation; and it was evident that in chronic pain one needed to recreate the nervous elements or to instil them with some electroid that should reset the spring of the machinery in motion, and guide it smoothly on its livelong bent. Nor, though it had been the quest of aeons, did this seem to be inexorably beyond the knowledge of the future.

This brief survey must suffice to show how much pathology there was yet in front of them, if the future was to be disentailed of its heritage of disease, and how difficult it must be to acquire the information necessary to enable them to bring the aid they would to sick humanity. The outcome seemed clearly to be—experiment, and ever more experiment. They came, indeed, back to Harvey's teaching—to search out the secrets of Nature by such means. The social instinct was hypersensitive to the use of this word in relation to disease. But why? He supposed that there had never been a dose of medicine administered—however much they thought to have divined its action—that had not been in some measure an experiment. Further, what else was it doing in the economy at large? Was its mission ended when the behests of the physicians were accomplished? There were some who thought and spoke of experiments as if they

(a) Abstract of the Harveyan Oration delivered before the Royal College of Physicians of London, on October 18th, 1912.

were performed only upon the lower animals and the poor. The fact was that by experiments the worlds had grown; experimentation was the one fundamental necessity of all progress; and the whole of animal life—life of every kind—to reap the benefit must share the risks and chance the pain.

THE WIDENING OF THE SCOPE OF ABDOMINAL SURGERY FROM LIFE-SAVING TO HEALTH-RESTORING OPERATIONS. (a)

By ARTHUR E. GILES, M.D., B.Sc., F.R.C.S.,
Surgeon to the Chelsea Hospital for Women; Gynaecologist to the
Prince of Wales' General Hospital, Tottenham.

It is interesting to recall the fact that abdominal surgery is only a little over a hundred years old; because, although various abdominal operations have been performed by heroic surgeons from the earliest times, it was the establishment upon a secure basis of the operation of ovariectomy that secured the proper recognition of abdominal surgery generally. The first successful ovariectomy was one of the triumphs of the New World, for it was performed by Ephraim McDowell, of Kentucky, in the year 1809. Naturally, this historical case did not by itself establish ovariectomy upon a secure basis; on the contrary, for many years there was much opposition and there were few cases. McDowell himself performed the operation only twelve times, with eight recoveries; and for the span of a generation the attitude of the profession was mainly one either of scepticism or of more or less thinly veiled disapproval. The next important advance was made by Charles Clay, of Manchester; his first successful ovariectomy was in 1842, and in all he operated on three hundred and ninety-five patients, with one hundred and one deaths, his mortality being thus about 25 per cent. Think of the courage that must have been required to persevere in the performance and the advocacy of an operation that was attended, at its best, with a mortality of 25 per cent. In 1861, Tyler Smith, speaking from the presidential chair of the Obstetrical Society of London, could utter these pessimistic words, "In the long run, I believe, the results cannot be favourable, either in general or special hospitals." Happily, Tyler Smith's gloomy forecast has not been fulfilled; and by way of illustration and commentary I may mention that at the Chelsea Hospital for Women during the twenty-five years, 1885 to 1910, eight hundred and forty-eight ovariectomies were performed, with forty-seven deaths, giving a mortality of 5.5 per cent.; and if we compare the beginning and the end of this period, we find that in the first five years there were seventy ovariectomies, with nine deaths, or 12.8 per cent.; whilst, in the last five years, there were two hundred and four ovariectomies, with seven deaths, or 3.4 per cent. The results in general hospitals, which at one time were deplorable according to our present standard, are now practically as good as in the special hospitals. Comparing my own cases at the two hospitals with which I am connected, one a general and the other a special hospital, I find that at the Prince of Wales' General Hospital, Tottenham, I have had one hundred and forty-eight ovariectomies with five deaths, a mortality of 3.3 per cent.; whilst at the Chelsea Hospital for Women I have had one hundred and six ovariectomies with three deaths, or 2.8 per cent. Naturally, the later results are rather better than the earlier ones; the figures for the last ten years, from July, 1902, to July, 1912, for the two hospitals combined, work out at two hundred and twenty-three cases with five deaths, or 2.2 per cent.

It would take too long to enumerate the successive steps by which the mortality of ovariectomy was progressively lowered; nor can I here pay the tribute of recognition and praise to the brave and brilliant workers who, through good and evil report, perse-

vered in perfecting the operation; it must suffice to recall that the three great factors that revolutionised the results of ovariectomy and laid the foundations of modern abdominal surgery, were, first, the discovery of chloroform anaesthesia by Simpson; secondly, the perfection of *technique*, in which Spencer Wells played such a notable part; and thirdly, the introduction, by the genius of Pasteur and Lister, of antiseptics and asepsis.

It is difficult for us to imagine the performance of an abdominal operation without anaesthesia; and when thinking of the pre-anaesthetic days, probably our first impulse is to thank heaven that we are not called upon to operate under such conditions. It is, therefore, a matter of great interest that we have preserved for us a record of the impressions of a man who operated both without and with anaesthesia. Charles Clay began his work before the discovery of chloroform, and one would have imagined that he would have viewed the introduction of anaesthesia with un-mixed satisfaction; yet, in 1863, when he had performed one hundred and eight ovariectomies, with seventy-four recoveries, he appeared to be distinctly doubtful of the value of anaesthesia; for in a paper entitled "Observations on Ovariectomy," we find this curious passage: "With regard to the use of chloroform, I am not certain if this agent has really added to the success of ovarian operations. The first fourteen of my cases were undertaken before it was discovered, and of these fourteen, nine recovered. But, though I willingly admit the almost impossibility of obtaining the consent of females (at the present time) to submit to so formidable an operation without the aid of this valuable agent, and though I am equally convinced that chloroform is of itself one of the greatest boons to suffering humanity, yet, if it could be accomplished, I should infinitely prefer to operate without it, as the patient would bring to bear on her case a nerve and determination to meet so great a trial, which would assist beyond all value the after-treatment; it would also relieve the case from that most distressful retching and vomiting so common after all abdominal operations where it is used to the extent that is required in ovariectomy."

Anæsthesia and improvements in *technique* conspicuously lowered the mortality of ovariectomy by lessening two of the great risks; namely, shock and hæmorrhage; but even so, the mortality was still very high. In 1878, when Spencer Wells had completed nine hundred cases, there were seventeen deaths in his last one hundred. This was because the greatest danger, that of septicæmia, had not been removed, and it was reserved for Lister to defeat this formidable enemy of the surgeon and of mankind. It is through his labours, and those of his disciples all over the civilised world, that we, at the present day, can undertake these serious operations with light hearts; and when I record before you my last ten years' results, with a mortality of a little over 2 per cent., I do so in no spirit of boastfulness or self-aggrandisement; but in doing so I place a wreath of veneration and gratitude on the shrine of the mighty dead.

The admission of ovariectomy to a recognised place in surgery was, of course, not a sudden event that could be assigned to a particular date, or even a particular year. The growth of its recognition was gradual, but we may say that twenty-five years ago this recognition was an accomplished fact. By this time, many surgeons, encouraged by the results of ovariectomy, were performing abdominal operations for other conditions. As far back as 1863, Charles Clay performed the first successful hysterectomy for fibroids by the intra-peritoneal method; and in the same year Koeberlé, of Strasbourg, carried out the first hysterectomy by means of the *serre-neud* and the extra-peritoneal treatment of the stump. In 1879, Lawson Tait performed the first operation for the removal of inflamed tubes, and the same year witnessed the performance of Battey's first operation, in which healthy ovaries and tubes were removed for dysmenorrhœa. In 1883 Lawson Tait established another record by operating successfully in a case of

(a) The address in Surgery delivered before the Canadian Medical Association, at Edmonton, Alberta, August 12th, 1912.

ruptured tubal pregnancy. But the conservative spirits in the medical profession twenty-five years ago opposed the performance of these operations, although they admitted the justifiability of ovariectomy; just as their predecessors of a generation previously had opposed the performance of ovariectomy; they said that fibroids and inflammatory conditions of the tubes did not endanger life, and that, consequently, it was not justifiable to operate for the relief of these conditions. Their opposition appeared, at the time, to be justified by the high rate of mortality, which then ranged from 20 to 30 per cent., whilst the mortality of ovariectomy had become reduced to from 10 to 15 per cent. But, happily for the race, there were surgeons who had the courage to persevere, believing that the mortality of these operations could be brought down, even as had happened with ovariectomy.

Thus the field of abdominal surgery became further extended; to enumerate only a few instances, we may mention the surgery of the appendix and gall-bladder, intestinal surgery, the operative treatment of gunshot wounds of the abdomen, and operations for intestinal obstruction. Even the field of obstetrics was encroached upon; for while obstetricians were discussing the relative value of craniotomy and induction of labour in cases of contracted pelvis and other forms of obstructed labour, the advance of abdominal surgery made Cesarean section a safe and satisfactory alternative procedure. At the present time the destruction of a living child, on the ground that there is an obstacle to its birth in Nature's appointed way, is viewed with increasing repugnance; and we may look forward confidently to the time when the performance of craniotomy on a living child will be considered, save in very exceptional circumstances, as a relic of barbarism, stamping its perpetrator as an ignorant bungler.

There is no doubt that, while the mortality of abdominal operations remained high, the scope of abdominal surgery was limited in proportion. It is only desperate cases that admit of desperate remedies, and as long as the risk of operation was greater than the risk of leaving matters alone, it was wise and practical advice to recommend patients to endure their sufferings with Christian resignation rather than face the risks of surgery; and patients would have been justified, when operation was advised, in replying in the words of King David, "Let me fall into the hands of God, rather than into the hands of men."

We now come to the consideration of what has happened in the last twenty-five years, and therewith to the more special subject of these remarks, which is the phenomenal extension of the scope of operations, not for the saving of life alone, but for the relief of suffering.

To illustrate how the field of operations has extended in inverse ratio to the rate of mortality, I cannot give you a more graphic picture than is presented in the records of the Chelsea Hospital for Women. I have investigated the records of all the abdominal operations performed at this hospital during the twenty-five years from 1886 to 1910; and grouping them in periods of five years each, we find the results as follows:

Years.	No. of Abdominal Operations.	No. of Deaths.	Percentage Mortality.
1886—1890..	126	27	21.4
1891—1895..	206	35	17.0
1896—1900..	879	50	5.6
1901—1905..	1,493	63	4.2
1906—1910..	1,880	54	2.8

Thus, while fifteen times as many operations were performed in the last five years as compared with the first five years, the percentage mortality was eight times less.

By way of further illustration, I will take two individual classes of operation, one for the removal of the tubes and ovaries for inflammatory disease, and the other, the removal of the uterus for fibroids. I have chosen these two, because, while these operations are performed in a certain proportion of cases for

the direct saving of life, their purpose is even more the relief of suffering and of chronic invalidism. The records of the Chelsea Hospital for Women, taken in the same way as before, are as follows:

OPERATIONS FOR TUBAL DISEASE.

Years.	No. of Operations.	No. of Deaths.	Percentage Mortality.
1886—1890..	12	4	33.3
1891—1895..	22	3	13.6
1896—1900..	198	7	3.5
1901—1905..	302	10	3.3
1906—1910..	363	5	1.3

HYSTERECTOMY FOR FIBROIDS OF THE UTERUS.

Years.	No. of Operations.	No. of Deaths.	Percentage Mortality.
1886—1890..	14	5	35.7
1891—1895..	12	5	41.6
1896—1900..	150	16	10.6
1901—1905..	345	18	5.2
1906—1910..	487	9	1.8

These figures show that, for tubal disease, the number of operations was thirty times greater in the last five years, compared with the first five, and the percentage mortality was twenty-six times less. In the case of hysterectomy for fibroids, the number of operations was thirty-five times greater and the mortality twenty times less.

I doubt if the whole range of surgery could show any other two operations that presented such an extension of scope and such a rapidly diminishing mortality within a space of twenty-five years. Surgery has long held an honoured place as the saviour of those doomed otherwise to die; the work of the last quarter of a century has given her an equally just and an even wider claim to be regarded as the restorer of those who are otherwise sentenced to what many feel to be worse than death, and that is, chronic invalidism and disablement.

A remarkable feature of this transition has been the corresponding change in the attitude of the general public towards surgical intervention. Formerly, an operation was regarded as a necessarily desperate remedy involving a perilous descent into the valley of the shadow of death; and it was only the power of a Christian faith or a stoical fatalism that enabled them, as Milton was taught by his Heavenly Muse,

"to venture down

The deep descent, and up to re-ascend
Though hard and rare."

The operating theatre presented itself to the popular mind as a chamber of execution, over which hung the sign of the dripping blade, while about it lingered the echoes of the last sighs of departing souls. Now this same theatre has assumed, rather, the character of a temple of healing, with the whilom executioner transfigured into the High Priest. That which was a River of Styx, dark and cold, is now a Pool of Bethesda; and the ill-avised and taciturn Charon has been metamorphosed into the angel that troubles the pool as a signal of healing. (a)

This change in the attitude of the public towards surgical operations is not limited to any one class; we find that the intelligent and highly-educated among our patients have a considerable knowledge of what is involved in various operative procedures, and of the attendant risks and after results; and, because they are well-informed, they exhibit a well-reasoned confidence in submitting to operative treatment. On the other hand, the patients that form the greatest proportion of our hospital cases have but little knowledge of what is implied by operation, beyond the fact that they are sent to sleep and something is done; but their readiness to accept an operation as the

(a) It may amuse our readers to see the following version of the above passage in the racy language of Western Canada, taken from the report of the address in the "Edmonton Bulletin," "Dr. Arthur E. Giles whispered to us in a confidential way that a doctor was not honestly represented by the drunken sailor, Charon, who offered to cross us over the river Styx in a trolley dug-out for two bits a head, but was really the patronizing barker for the pool of Bethesda, who called out in a mellifluous tone: 'Come on in, the water's fine.'"

proper treatment for them is equally great; all they ask is the assurance that it is for their good and that they will feel nothing; and we find that their confidence is born of their experience of what such treatment has done for their friends.

There is no doubt that implicit confidence on the part of our patients imposes upon us an added burden of responsibility in deciding what advice we are to give them, for, if their confidence is small, they will probably seek and obtain several opinions, and then make their own choice; but if their confidence is great, they will accept our opinion without question and act upon it without demur. But when the stage of advice is passed and that of action is entered upon, this confidence is of the greatest value to us, because the success of our operative work is immeasurably assisted by the trustful co-operation of our patients. This is true of those conditions involving questions of life and death, where it is our duty to say, "You must undergo an operation in order that your life may be saved," and it is equally true of those conditions where an operation is a matter of choice rather than of necessity, and where our formula will rather be this, "You will be well-advised to undergo an operation in order that your health may be restored." In my own practice, the distinction that I adopt is, that I *urge* an operation of necessity, and if the patient appears unwilling I use all my powers of persuasion; but I *advise* an operation of election, and after explaining the pros and cons I leave the choice to the patient.

I have dwelt at some length on this question of the attitude of our patients, because it is a most important factor in the consideration of operations for the restoring of health, as distinguished from operations for the saving of life.

Let me now say a few words about some of those conditions, in the department of gynecology, whose treatment by surgical means has been rendered possible by the fall in the death-rate of abdominal operations.

We may begin with uterine displacements. These are conditions that never prove fatal, and therefore we could not advise for their relief any operative treatment that was attended by an appreciable mortality. And so it was only when the mortality of abdominal operations generally was showing a marked decline that the surgical treatment of displacements came into vogue. It is interesting to note that the first abdominal operation for retroversion was an extra-peritoneal one, namely, the Alexander-Adams operation; at that time the peritoneal cavity was still a kind of "*noli me tangere*," and every time it was opened there was a threat of septicæmia. Modern asepsis has robbed cœliotomy of its terrors; we have learnt the ways of the peritoneal cavity, and ceased to fear it. We now know that if we can leave the vulnerable diaphragmatic area alone, and avoid undue handling of the bowel, and refrain from introducing into the peritoneal cavity irritant chemical antiseptics, the peritoneum is a tolerant structure well capable of looking after its own interests.

It was not long, therefore, before intra-peritoneal operations were introduced for the treatment of displacements, most of them originating on this side of the Atlantic. We had ventrofixation and ventro-suspension of the uterus, with their modifications, and the various procedures for the intra-peritoneal shortening of the round ligaments. It is not necessary in this place to discuss the merits and demerits of these different operations: the one chiefly practised at the Chelsea Hospital for Women has been what we call hysteropexy, and in the twenty years, from 1891 to 1910, this operation was performed in five hundred and eighty-four cases.

The value of these operations is two-fold: in the first place, many patients are cured who cannot be relieved by other means, for example, cases of adherent retroversion and some cases of prolapse and procidentia. In the second place, patients can be saved from years of pessary treatment. I have before now defined pessaries as a necessary evil, that is, they are necessary sometimes, but evil always; and I have found no reason to alter this definition. It would be

possible to draw up a serious indictment of pessaries: the unpleasantness of frequent examinations; the drawback of being chronically under the doctor's hands; the discomforts of irritating discharges and their attendant douchings; the risk of serious ulcerations into the bladder and rectum, of septic infection, and of the development of carcinoma as the result of retained pessaries, examples of which I have seen. If, by means of a safe operation, patients can be saved from all this, and if they desire such relief, surely they are entitled to have it. The radical cure of hernia is considered justifiable, to obviate the discomfort of constantly wearing a truss; why not then the radical cure of a uterine displacement, to obviate the necessity for the more obnoxious pessary. Well, the progress of abdominal surgery has opened up this field of relief to women and it has resulted in a wide relief of suffering and emancipation from disablement.

Passing on to the subject of inflammatory disease of the uterine appendages, we have to do with a somewhat graver condition, because, in a certain proportion of these cases, the patient is seriously ill, and we are called upon to operate in order to save life; and with the remainder, which forms the great majority, it is not a matter merely of obviating discomfort, but it is a question of saving women from prolonged illness, constant suffering, more or less complete invalidism and disablement. Some of these women, in the poorest classes, are the bread-winners, and for them disablement is a worse evil than death.

Now, as long as the operative mortality was high, these patients could not be advised to undergo surgical treatment; and up to twenty years ago the mortality ranged from 20 to 30 per cent. It is true that Lawson Tait as far back as thirty years ago (or, to be precise, in 1883) was able to record sixty-two cases without a death; and his results justified him in taking up a position far in advance of the current medical opinion of his time, and in saying "we could not stop short of dealing with matters that affect life only. Hydro-salpinx was a frequent cause of the most intense suffering, and therefore he would, and did, remove it by surgical operation without hesitation." By degrees, as the figures of the Chelsea Hospital for Women show, the mortality became lower and lower, the figures for five successive quinquennial periods being, 33.3, 13.6, 3.5, 3.3, and 1.3. It was not, however, on the ground of mortality alone that these operations met with opposition in certain professional quarters; it was objected that after these operations, patients remained chronic invalids, that they were unsexed and rendered unfit for wifehood, that they became, at the best, hysterics and at the worst, lunatics. These objections were chiefly theoretical; and two years ago I was able to show, from a detailed investigation of the after-results of these operations, based on two hundred cases in which both ovaries were removed, that 70 per cent. of the patients regained perfect health and vigour and retained their sex-instincts; that the legends of women developing bass voices and growing beards were pure romance; and that there was no more tendency to insanity after double ovariectomy than there was after any other abdominal operation.

Now, what happens to patients suffering from chronic pelvic inflammation who are not treated by surgical means? Here and there we may find a case where symptoms subside and health is more or less completely regained; but this is a rare event. Many of these patients swell the ranks of those who are unjustly described as hysterical and neurotic. How often it has happened to me to have a patient sent up with a letter saying that she exhibited marked neurotic tendencies; and on examination some chronic pelvic disease has been discovered. These cases have constituted in the past a great reproach to the medical profession; such patients often suffer intermittently; they are seldom acutely ill, but they are never completely well; and because there is not much to show for their sufferings, and because, on occasion, they are able to make an effort to appear as other women, they have been treated as neurotics and almost as malingerers; they have been drenched with bromides and

valerian; they have been sent from spa to spa^m and soaked in brine-baths and mud-baths; they have been driven to seek relief in alcohol, morphia, or cocaine; or they have found a doubtful haven among the faith-healers and the Christian Scientists. I contend that we have no right to label any woman as neurotic, unless we can be certain that she has no organic disease; and even then we shall be wiser if we suspend our judgment.

Think of the amount of suffering saved, the workers that have been restored to the position of earning their livelihood, the relief to the community in the conversion of dependent invalids into sound and useful members of the body corporate; think of all this amount of good done as represented by the eight hundred and forty-one women who have been cured of diseased appendages in the last fifteen years at the Chelsea Hospital for Women. Then add to these the thousands of women similarly cured in other institutions all over the civilised world, and you will gain some idea of the good that has resulted from the decreased mortality of abdominal operations.

We come, thirdly and lastly, to the subject of fibroid tumours of the uterus. Here we have a condition more inherently dangerous than the other two, leading more often to a directly fatal result; and, short of a fatal issue, causing prolonged suffering and disablement. Here, again, we have a condition in which the operative death-rate must exert a marked influence on the advice that we give to our patients. Twenty years ago this operative death-rate was from 20 to 40 per cent.; and it is evident that it was only in cases where a fatal result was threatened that so dangerous an operation could be recommended. In the much larger majority of cases, there was no question of life being at stake, the reason for operation would be only the relief of suffering, and it is seldom that patients yearn for death or are willing to incur a very great risk, merely to be relieved of suffering. It is better, after all, to live as an invalid than to die cured. Now when a patient with fibroids has to be told that the resources of medicine are exhausted and that the succour of surgery is more cruel than kind, it is a great comfort to be able to hold out some kind of hope, however unsubstantial; and so a fairy tale was built up and decorated to represent a scientific theory, to the effect that the menopause was the natural cure for fibroids. And patients were told, in all seriousness and good faith, "You must wait for the change of life, and then these tumours will shrink and disappear and you will get well." And the patients went on patiently draining their life-blood away, carrying enormous tumours that prevented them from getting about, hoping against hope that the delayed menopause would arrive, like some millennium, to give them peace. Some of them survived the worst troubles and escaped with their lives, a few of them regaining a measure of health, and the remainder remaining more or less permanent invalids. Others found that the menopause, when it came, came not to bless but to curse, bringing in its train degenerative changes, infection, sepsis, and death. Now I do not know what is the state of current medical opinion in progressive Canada; but I can tell you that in some parts of the Old Country we find a tragic thing, and it is this: That while the operative conditions have revolutionised the death-rate of hysterectomy, causing a drop from 30 to 2 per cent., the hoary myth of the menopause is found to survive, even in high places, and patients are still condemned to years of suffering who might be quickly and safely cured. Look once more at the record of hysterectomies for fibroids at the Chelsea Hospital for Women; observe that in the last five years under consideration four hundred and eighty-seven operations were performed, with a mortality in all cases—serious as well as simple—of 1.8 per cent.; and I think that you will agree that I am justified in the contention that all fibroids should be operated upon (unless some weighty reason to the contrary can be shown) in the early stages, as soon as symptoms arise, and without waiting for the development of grave complications; and that, whereas in

the early days hysterectomy had to be reserved for cases in which it was required for the saving of life, the progress of abdominal surgery has brought it within the scope of operations that are justifiably performed for the relief of suffering and for the restoration of health.

In bringing these somewhat fragmentary remarks to a close, it may be well to guard against one possible misconception. Let me then state explicitly that the fact that an operation is safe is not, in my opinion, a sufficient reason for operating, if a cure can be obtained by other methods. I have no sympathy with the attitude of mind of Tennyson's imaginary surgical enthusiast, described in the lines—

"indeed, it was said of him

He was happier using the knife than trying to save the limb."

On the contrary, I am not ashamed to admit that I have a feeling of reverence for the human body; and that, in my opinion, the only sanction that can be accorded to surgical interference is that which is derived from the conviction that life, health, or comfort must otherwise be sacrificed. Having made this surgical profession of faith. I feel bound to state my belief that, on the other hand, we are not justified in refusing surgical relief when health and usefulness are at stake, any more than we should be entitled to withhold the aid of surgery when life is threatened—provided always that the ratio of the operative risk to the risk of non-interference be accorded its proper weight and consideration. In other words, while the grave issues of life and death justify great risks, the lesser issues of health and infirmity warrant only slight risks. It has been my object to show that the development of abdominal surgery and the extension of its scope have enabled us to realise the harmonious adjustment of this ratio, and to place the resources of our surgical art, with ever-lessening risk, at the disposal of an ever-widening circle of humanity.

PULMONARY TUBERCULOSIS AND MEDICAL GYMNASTICS.

By FILIP SYLVAN, M.D. BERLIN,

London.

I BELIEVE it is an accepted fact that to get consumption a certain special tendency is required, without which the tubercular bacilli cannot live in the lungs. What constitutes this tendency?

Looking at the principal symptoms of consumption, we find that one is a shortness of breath. The patient gets out of breath by any slight exertion. What does this mean? I venture to say it is a sign of weakness in the inhalatory power or in other words the (*tone*) tonic contraction of the respiratory organs is decreased. The muscles themselves may not be weak, but the breathing centres in the medulla or in the cortex are weak. From a clinical point of view, the centres in the cortex are of supreme importance, because according to the general rule the higher centre has always a greater influence on the lower centre. Therefore, if we can affect the centre in the cortex, this will automatically affect the centre in the medulla. Many writers (Danilewsky, Unverricht, Krause, Horsley, Preobrazenski, Bechterew, &c.) have studied the cortical centres of breathing in animals. I believe the latest view is, what Bechterew ("Functionen der Nervencentra," 1911) found in apes, two cortical centres for breathing, one situated a little in front of the upper end of the sulcus præcentralis, the excitation of which causes an instant cessation of the breathing at inspiration, another situated in the frontal lobe, a little lateral and frontal of the above mentioned.

By excitation of the latter the breathing became more superficial and frequent. We may assume that in man the cortical centres for breathing are the same.

When the carbonic acid in the blood exceeds a certain amount, it excites the breathing centre in the medulla and increases the breathing. As regards the cortical centres these seem to have a more voluntary influence on the breathing; and to strengthen the inspiratory tone we must bring the effect to bear especially upon the first of the above-mentioned two cortical centres, which most probably can be regarded as being an inhalatory centre.

Several writers (Bechterew, &c.) during their experiments noticed the intimate connection between the motor and breathing centres.

The system of association-tracts constitutes the connecting link between one sensitive-motor centre and another, so, for example, from vision to the hearing centre, from smell to vision or from motor to breathing centre. If in two sense-centres of the cortex simultaneous or following excitations take place, then, by virtue of the existence of association tracts, only one of these excitations needs afterwards to be repeated to animate the perception in the other sense-centre. (Bechterew.)

Apply this rule in our case in the following way. Let the patient make a movement and let him inhale deeply at the same time. When he has been doing this for some time, as soon as he starts the movement, he will by virtue of the existence of association tracts, unconsciously breathe more deeply. Of course in practice it is not quite so simple. There are so many special points of great importance. It is not sufficient to let him go through only one exercise. He must in the same way combine the act of inspiration with the motor function of every muscle-group in the body, thus the patient will always breathe deeper as soon as he starts any kind of movement. To make the movement a resistance exercise (see books upon Swedish Medical Gymnastics), the effect on the cortical centres will be considerably increased and I conclude that it is principally in this way that the tone of the inspiratory centre is strengthened.

I may perhaps specially point out that when treating consumptives with gymnastic exercises all the rules of Ling's system (usually called Swedish Medical Gymnastics) must be very correctly followed, otherwise the result must fail. But also the above points must be closely kept in mind. I may here mention that long before I had the theory mentioned in this paper, I used gymnastic treatment for consumptive patients with very satisfactory results, but these results have been far exceeded by the results of the same kind of treatment since I directed the effect principally upon the strengthening of the inhalatory centre and affecting a hyperæmia in the lungs. I cannot here enter into details of the gymnastic treatment, but I have noticed that certain exercises are injurious at a certain stage, but can be used later on with advantage. The first and supreme rule must always be that the patient never has to make any effort, as this would have the contrary effect. Bechterew found that new or strong excitations had a lessening effect on the associative reflex. Therefore we must start with very easy exercises and only very slowly and gradually proceed to stronger ones.

A stronger inhalatory centre will, of course, bring about deeper breathing and so facilitate the taking up of oxygen by the blood, but in strengthening the inhalatory centre I have quite a different object in view, which I believe is of far vaster importance to sufferers from pulmonary tuberculosis. The researches of Kisskalt (*Archiv. für Hygiene*, Bd. XXXIX. p. 142) show that the development of bacilli is very often checked by venous hyperæmia. When the inhalatory power increases the inspiration will be done much stronger and deeper, and the air pressure in the lungs decreases, which results in a dilatation of the blood vessels and a hyperæmia which arrests the development of the tubercular bacilli. It is this same effect which is brought about by consumptives going up in the mountains; a decrease of the air pressure in the lungs, which results in a hyperæmia. This effect, however, passes off when the patient becomes acclimatised. But the effect of the gymnastic treatment (when properly carried out after here mentioned principles) is far greater than that of the lower air pressure in the mountains. Another great advantage is that the gymnastic treatment can be carried out anywhere.

E. Weber (*Archiv. für Anat. u. Physiol.*, 1911, p. 377) has shown that the excitation of sensitive nerves results in a dilatation of the blood vessels of the lungs. To this effect I give pétrissage of the back on both sides of the spine where all the nerves emerge from the spine.

Thus in two different ways I bring about a dilatation of the blood vessels and hyperæmia in the lungs. One might think that this would easily result in a hæmorrhage, but that is not the case; in fact, I have never met with one single hæmorrhage during the period of my treatment, although several of my patients had previously repeatedly suffered from hæmorrhages. I explain this by the fact that the gymnastic treatment has a good effect on the general nutrition and thus has a strengthening effect on all the organic tissue. Consequently a hæmorrhage does not occur so readily.

I consider the general effect of the gymnastic treatment to be of great importance; it increases the appetite and metabolism, and as long as the body has a surplus of nutriment no waste of lung tissue seems to take place. This is the reason why overfeeding is good for consumptives. In this connection I should like to point out that my consumptive patients did not put on any fat and the increase of their weight has been in some cases only 2 lbs., in other cases 4 or 5 lbs., during the time of treatment, but this very slight increase in weight corresponds to an increase in organic tissue, not in fat. I believe that a person who is quite healthy, and who eats normally does not put on any fat. Consumptives cured by gymnastic treatment do not, as a rule, put on any superfluous fat, and there is really no need for it.

For treatment of catarrh in the lungs, I make a tapping with the fingers and vibrations on the chest, during which the patient must breathe deeply. After the patient has been under treatment for some time, I add to the exercises a passive expansion of the chest. This must in the beginning be done very carefully, because often after pleurisy there are adhesions, and if these are too violently broken, inflammation and fever

might result. If done carefully the adhesions become relaxed, and disappear in a short time.

As regards fever, I never met with any rise of the temperature after I had started the gymnastic treatment. It is in the nature of this treatment that it rather prevents fever. Fever, I believe comes on when the blood has not a sufficient supply of oxygen, but as the gymnastic treatment facilitates and increases the supply of oxygen, it is obvious that no rise in temperature is to be expected during the gymnastic treatment.

The explanation of the good effect of manual labour and exercise which has been used in many sanatoria is, in my opinion, that it stimulates the general nutrition (metabolism), and to a small extent it increases the breathing. Dr. Inman (*Lancet*, 1908, p. 220) explains the satisfactory results obtained from the system of graduated labour, saying that the work causes an inoculation of the patient by his own tuberculin. Dr. Paterson (*Lancet*, 1908, p. 216) supports this theory by the fact that after a rise of temperature, and therefore an auto-inoculation, patients were often better than before, and that patients who were not improving on a certain grade of work, did improve on harder work. His theory is that the harder work gives rise to an auto-inoculation, whereas the lighter work fails to do so.

I cannot agree with this theory at all. The fact that some patients improved on harder work and not on lighter work is to be explained in a much simpler and more probable way. The harder work made them breathe deeper, and the lighter work had no effect on their breathing. The amount of muscular exercise necessary to stimulate the breathing varies considerably with different persons. In other words, the patients who only improved on harder work, required a greater percentage of carbonic acid to stimulate the breathing centre in the medulla, and in this way they increased their inhalatory power to a small extent. But the effect of manual labour in this respect is quite insignificant, compared with the effect of gymnastic treatment carried out in the way and after the principles I have described.

The results of the gymnastic treatment as I have carried it out are the following. During the first week a patient feels easier in the chest, he can breathe easier and his appetite increases. During the second week in many cases there was a marked decrease of crepitation, and the patient could extend his chest better and felt generally much relieved. After the second week the progress depends upon many other circumstances, if the patient can have proper rest, or if he works, and what sort of a constitution he has. If a patient was at work when he came to me, I let him always continue his work as before, and the result was very satisfactory. As a rule if the patient was in the second stage of the disease, after about two months' treatment the physical signs of consumption disappear, the patient feels perfectly well and fit for work. As a precaution I have always prescribed a few exercises to every patient when he had finished the treatment, which he continued to do, at home, and usually after some time I examined him again to see that the result was lasting, and I am glad to say that it has been so in every case I have treated up till now. It is quite natural that I found patients with strong and good constitutions recovering very quickly, even in less time than two months.

But if consumption was combined with neurasthenia, it took a considerably longer time to reach a complete recovery. The explanation of this fact I will spare till some other opportunity. In one case of infiltration of the upper left lobe and neurasthenia, the patient needed ten weeks to get quite well and as it is now six months since I finished the treatment, and he is still perfectly well, I consider the cure is permanent. Another case where all five lobes were in the second stage was cured in exactly two months, and it is now twelve months since the patient left me, and he is still perfectly well.

When a patient is in the third stage, it is difficult to speak of cure as the wasted lung tissue cannot be restored. But even in such cases I have been successful, so far that the patient gets practically well and fit for work. But the success in the third stage is of less importance, because when the gymnastic treatment has come into general use, the patient will not reach that stage. But I consider the fact of having been successful also in cases of the third stage to be a strong evidence of the correctness of my theory.

OPERATING THEATRES.

MIDDLESEX HOSPITAL.

MILIARY TUBERCULOSIS, CARIES OF SPINE, DOUBLE PSOAS ABSCESS AND APPENDIX ABSCESS—APPENDICITIS—DEATH FROM SECONDARY INFECTION OF A PRE-EXISTING PSOAS ABSCESS.—MR. SAMPSON HANDLEY operated on a boy, *æt.* 18, who had been admitted to the hospital with the following history:—The only previous illness was chicken-pox when two years of age; there was no history of tubercle in the family. Eighteen months ago the patient was working in a hay-loft in Canada, when he fell through a hole in the floor to a distance of 30 feet, and landed on his back. He rested for a week, and was then able to return to his work. Eight months after the accident he complained of a dull aching pain in the lower lumbar region, which was not so severe as to prevent him following his occupation—namely, that of a farm labourer. This pain continued until seven days before admission, when he attended the out-patient department of the hospital, and was given a plaster to be applied over the lumbar region, and the pain disappeared. Two days later he had severe pain round the neighbourhood of his umbilicus, which lasted for a few hours, and then was felt in the right iliac fossa. He vomited all food after taking it and had diarrhoea continuously until admission. On admission he was slightly cyanosed, with an anxious, pinched expression, pulse 84, temperature 97° F. The extremities were cold, the tongue dry, and covered with a thin layer of yellowish-grey fur; the abdomen moved on respiration, it was not rigid, but just internal to the anterior superior iliac spine could be seen a fulness, and a swelling was felt about the size of a small apple, which did not fluctuate, but was very tender on pressure. On examination per rectum the right side was very tender. Hot fomentations were applied over the iliac fossa and hot bottles put round the extremities. Five hours after admission the temperature had risen to 100.8° F. and the pulse to 100. Four hours afterwards the temperature was 102.6° F, and the pulse-rate had fallen to 88. The blood-count was 5,280,000 red, 13,000 white. An hour later the patient was taken to the operating theatre, and Mr. Handley opened the abdomen, using Battle's incision. Pus immediately escaped when the peritoneal cavity was opened. The appendix was found to be gangrenous and perforated near the tip; it was ligatured at its junction with the caecum and removed; two drainage tubes were inserted and the abdominal wall sutured by means of through-and-through sutures. The patient was taken back to bed, continuous saline per rectum being given. A fortnight afterwards the tubes

were removed and the patient made an uninterrupted recovery and was sent to Clacton Convalescent Home, the wound having completely healed. At this time nothing abnormal was detected in the region of the dorsal or lumbar spine.

Three months subsequently the patient was readmitted into the Middlesex Hospital under Dr. Pasteur with abdominal pain. On the following morning he was seen by Dr. Lakin, who sent for Mr. Handley and asked him to see the case, as the patient had previously been under Mr. Handley. Mr. Handley immediately recognised the boy. On examination a red, painful, tender swelling was found in the region of the old scar. He was at once taken to the operating theatre. An incision three inches long was made just behind the scar, and a large quantity of foul-smelling pus immediately escaped. On exploration with the finger a large cavity could be felt behind the peritoneum extending as far as the finger could reach. A counter opening was made just behind and two large drainage tubes put in. The bacteriological report was a pure culture of *B. coli*.

Owing to the temperature rising at night and falling in the morning, and as nothing surgical could be found to account for this phenomenon, Dr. Pasteur was asked to see the patient, but he could not detect any adventitious sounds in the lungs. Six weeks afterwards an exploration was made under CHCl_3 by Mr. Handley. An abscess cavity was found to be present in the right psoas muscle, a sequestrum of bone was removed, and a lumbar drain inserted. A fortnight later the patient was again seen by Dr. Pasteur, who said there was evidence of breaking down of both lower lobes. Two days subsequently the patient complained of frequent cramp-like pain in the limbs. There was no discharge from the lumbar wound, and the tube was removed. Later the man became delirious at night, his general condition became worse, and he died in a few weeks.

The *post-mortem* examination revealed the thymus considerably enlarged; all the mediastinal glands were also enlarged, but were not tuberculous. Both lungs, chiefly towards their bases, were the seat of numerous small tuberculous deposits, which were caseating. The pleura was adherent on both sides (recent adhesions). The mesenteric glands were enlarged. There was considerable matting and many adhesions of the intestines in the neighbourhood of the appendix operation; otherwise the intestines were normal. A psoas abscess was present on each side. The bodies of the 12th dorsal and 1st lumbar vertebrae were carious.

The President, DR. AMAND ROUTE, in the Chair.

A CASE OF HÆMATOCOLPOS, WITH REMARKS ON THE STRUCTURE OF THE VAGINAL WALL.

BY R. DRUMMOND MAXWELL, M.D., F.R.C.P.

ABSTRACT.

THE patient, æt. 19, had been married a few months, and came to the hospital complaining of dyspareunia. There was no abdominal swelling, and the external genitalia were normal; the introitus vaginae was closed by a thick, fleshy septum, and when pressure was applied to the hypogastrium this septum did not bulge at all. Rectal examination showed the presence of a large, tense, cystic, intrapelvic swelling, whose lower pole appeared to be about $\frac{1}{2}$ inch above the septum; it was about the size of the uterus at the twelfth week of gestation.

The physical signs suggested a hamatometra, rather than a hamatocolpos, and it was in consequence expected that some disorganisation of the tubes would

have occurred. Laparotomy was, therefore, performed, but the uterus and appendages were found to be perfectly normal. The supra-vaginal cervix was slightly dilated, and disappeared into the tense, cystic mass. The abdomen was at once closed, as it was recognised that the condition was retention in the upper two-thirds of the vagina, the lower third not being canalised. Guided by two fingers in the rectum, an incision was made with scissors closely following the floor of the urethra, into which a sound was inserted. After blunt dissection upwards for about $1\frac{1}{2}$ inch, the lower pole of the swelling was reached. Before opening this it was freed from the para-vaginal cellular tissue, to enable a tube of it to be drawn down and stitched to the introitus. A little more than a pint of unusually thick tarry fluid was evacuated, and the circular edge of the tube was drawn down so as to project beyond the vulva. A thin strip of tissue was removed from both the anterior and posterior vaginal walls for microscopic examination.

The hymeneal tissue showed the typical appearances described by Blair Bell. The vaginal wall was covered by epithelium, consisting partly of stratified cells and partly of high columnar richly muciniferous cells. In some places the columnar cells are superimposed on several layers of stratified epithelium; in other places the columnar cells are being shed so as to allow the stratified epithelium to appear. This appears to negative the view that the stratified epithelium spreads upwards from below and replaces the columnar cells, but suggests that the Malpighian layer of the skin first produces columnar muciniferous cells, and later on a stratified layer. The author suggests that the initial function of the columnar layer is to canalise the vagina by pressure from its mucin secretion. Several pseudo-glandular crypts, lined by columnar cells, and a few definite racemose glandular spaces, were also found.

The paper was discussed by Dr. Russell Andrews, Dr. Spencer, Dr. Stevens, Dr. Eden, Dr. Griffith, and the President.

ON GELATINOUS GLANDULAR CYSTS OF THE OVARY, AND THE SO-CALLED PSEUDO-MYXOMA OF THE PERITONEUM.

BY THOMAS WILSON, M.D.LOND., F.R.C.S.ENG.

ABSTRACT.

CERTAIN glandular proliferating cysts of the ovary are made up of solid jelly-like material in a multitude of small loculi with delicate transparent walls, which are prone to rupture and allow a free escape of the gelatinous contents into the peritoneal cavity. Here the gelatinous substance adheres closely to the parietal and visceral peritoneum, and even finds its way on to the upper surface of the liver, spleen, and stomach; the omentum usually forms a very thick, hard plate. Such cases were formerly known as colloid cancer of the peritoneum or ovary, and may be conveniently termed pseudo-myxoma of the peritoneum; they probably form 2 to 4 per cent. of the cases of ovarian glandular cysts.

Firm gelatinous cysts of the ovary that have not ruptured are also met with; but these are found usually in single and nulliparous women under 40, while true pseudo-myxoma is found most frequently in married multiparæ between the ages of 40 and 60.

The onset, symptoms, and physical signs of pseudo-myxoma of the peritoneum do not differ notably from those of the ordinary glandular ovarian cyst, and in none of the six cases here related was there any symptom or sign of previous perforation or rupture of the cyst wall; neither was the peculiar nature of the ovarian affection suspected in any of them until the abdominal incision was made.

The affection of the ovary is unilateral, the pedicle usually well formed, the Fallopian tube and mesovarium generally unaffected. The gelatinous substance contains pseudo-mucin, the cysts are lined by a single layer of typical secreting epithelium. The parietal and visceral peritoneum in contact with the effused jelly may be unchanged, but usually shows signs of chronic irritation due to attempts to absorb or encapsule the gelatinous substance. In a certain number of cases true implantation metastases with living and active secreting epithelium are found.

either on the surface or in the spaces of the subserous tissues. In one case seen in the *post-mortem* room, and apparently belonging to this group, a large, gelatinous, metastatic growth was found in the middle lobe of the right lung.

The treatment, formerly very unsatisfactory, appears to have improved considerably of late years. Paracentesis is useless and highly dangerous. The most important point is to remove the gelatinous material as completely as possible, and this is best accomplished by copious flushing with normal saline solution, which causes the jelly to swell up and become loosened from its attachment. Even in favourable cases the prognosis as regards freedom from recurrence must be doubtful, since small collections with living epithelium may lurk unobserved in some of the recesses of the peritoneal cavity, and burst into renewed activity after a longer or shorter time.

The notes of six cases are given, in one of which there were true metastases. Four of the cases have remained well after operation for periods varying from one to more than eight years. A chronological list of references is appended.

The paper was discussed by Dr. Russell Andrews, Dr. Munro Kerr, Dr. Herbert Spencer, and Dr. Eden.

EDINBURGH ROYAL MEDICAL SOCIETY.

INAUGURAL MEETING HELD FRIDAY, OCTOBER 18TH, 1912.

The Vice-President, Dr. RITCHIE, in the Chair.

THIS the 176th Session of the Society was opened with an address by Dr. ROBERT HUTCHISON, of London, a former member and President of the Society.

Dr. Hutchison, who was received with great cordiality by an excellent audience, said that it seemed only a week or two since he had been an active member, although actually twenty years had gone by since he joined the Society. He recalled Bacon's well-known adage that "reading maketh a full man, conference a ready man, and writing an exact man," and taking it as his theme he developed it in an interesting address on the place of such a society in the medical curriculum. In their splendid library they had ample material for reading, and there they ought to learn to read in the proper way—to get up information about subjects which they were really interested in for the time being. Next to being well read in a subject, came the ability to find out in what books the best information could be obtained. If the student learned nothing else than how to use the *Index Medicus*, he had gained a great deal. He thought that the student ought to depend largely on text books, and lesson journals, in his work. Ephemeral literature was rather dangerous fare. The older writers of last century ought never to be neglected. In reading them one missed, perhaps, the scientific treatment of to-day, but one gained a more practical view point than that induced by much of the present-day laboratory work; one came to see that many so-called new discoveries were in reality but old truths; and last one found that a text-book need not be dry, but might have charm and literary style. He also advised the Library Committee to consider the addition of a department of general literature, because the doctor of to-day must needs be a well-read man. The debates supplied the readiness of mind begotten by what Byron called conference. The doctor's work was, above all things, practical, and his knowledge was useless unless it was ready to hand in an emergency. Besides, now that the medical profession was consulted by public bodies as it never had been before, it was very essential that a doctor should be able to state his views concisely and clearly. The art of speaking could only be acquired by practice, such as the debates there afforded. It was their duty in these debates to theorise to their hearts' content. Later, they would find the mass of facts they acquired quite enough to weigh them down and stop undue theorising. Another most valuable qualification for a doctor which could be acquired at

the meetings was the power of suspending the judgment until all the facts were known—and, lastly, they would learn, some of them at least, to bear with fools gladly. The writing of a dissertation, which was still a rule of the Society, was introduced at a time when the defence of a thesis formed part of the examination for a medical degree. These compulsory dissertations were, he believed, a most important feature of the Society's work. When they came to write them, they would often find, in the first place how little they knew of the subject, and, after the material was arranged and written out, they would have a lasting possession in the shape of a more or less complete mastery of some topic. In looking through old dissertations, he had been struck with how often a man's bent was determined by the subject he chose. Sir James Simpson, for instance, had written his dissertation on disease of the placenta. Lastly, he emphasised the value of the Society as a place of social reunion, and a nursery of life-long friendships.

Dr. ALLAN JAMIESON proposed a very hearty vote of thanks to Dr. Hutchison for his very valuable address.

After the address, Mr. R. B. SIMPSON presented to the Society a gold medal which the Society had given to Mr. McFarlane, who was their Treasurer from 1828 to 1862. The medal had remained in Mr. McFarlane's family, and now the last survivor wished to return it to the Society for preservation and safe keeping.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, Oct. 19th, 1912.

At the International Kongress für Geburtshilfe und Gynäkologie,

THE SURGICAL TREATMENT OF UTERINE HÆMORRHAGES IN PREGNANCY, LABOUR, AND CHILDBED

came up for discussion.

Hr. Couvelaire was the first speaker, and he said that French obstetricians in cases of obstetric hæmorrhages adopt the non-chirurgical methods of arresting them. As far as chirurgical measures were followed at all they restricted them to cases in which the usual methods had proved themselves useless or were dangerous. Undoubtedly, chirurgical measures often gave quicker and more easily attained results. But the result of these, independently of the fact that they were not constant, included a certain maiming or diminution of capacity for reproduction on the part of the patient. With the exception in which surgical treatment was to be preferred one must acknowledge that improvement in therapeutical results was due less to an extension of groundless surgical methods than to medical treatment of pregnant women and the perfecting of the medical education of physicians and accoucheurs.

Hr. Jung, Göttingen, said that myomata that bled during pregnancy were always seated in the collum uteri. Here surgical removal was always indicated. If the myoma led to abortion, extirpation of the myomatous uterus was called for; it was to be preferred to a conservative treatment, as with that infection was liable to occur.

Carcinomata in pregnancy, when operable, were to be removed without any regard being had to the pregnancy. If not operable at the end of the pregnancy that patient was to be delivered, either through the vagina or by the classical Cesarean section. In case of penetrating wounds of the pregnant uterus laparotomy should always be performed, and the uterus treated according to the condition met with. If necessary it should be emptied, if not, the wound should be closed by suture.

In case of separation of the placenta prematurely the patient should be delivered, and if this could not be done either by the forceps or turning after dilata-

tion of the cervix, it would be best done by anterior colporrhaphy, that was if the pelvis was a normal one. In contracted pelvis some form of Cæsarean section was called for.

In the slighter cases of placenta prævia metretresis was the procedure of choice. Cases of total placenta prævia should be treated by anterior colpohysterotomy, with contracted pelvis Cæsarean section would be called for.

Rupture of the uterus should in any case be treated surgically, it was best done by laparotomy; the uterus could then be removed or the wound closed by suture, according to circumstances. Suturing through the vagina could only be successful where the rupture was incomplete. Tamponade as an assistance in emergency should only be made use of in rare cases. In cases of atony contractions of the uterus could be excited by tamponade of the vagina. It was only when these means failed that rapid total extirpation of the uterus, either by the vaginal or abdominal route, came into question.

Myomata that gave rise to hæmorrhage during childbed were to be extirpated, either vaginally or through the anterior abdominal walls. Infected myomata were also to be removed. Carcinomata when operable were best removed through the abdominal walls. In other cases of extreme hæmorrhage from wounds, placenta prævia, atony, many cases could be saved by temporary compression of the abdominal aorta. Momburg's tube compression was at present the best procedure for compression of the aorta.

Hr. Rübsamen, Dresden, introduced the subject of
POST-PARTUM HÆMORRHAGE.

in a paper in which he reported on some experimental inquiries he had made into the matter.

In the first place he showed in a graphic manner that pituitrin given in the afterbirth period increased the activity of the uterine contractions in the sense of shortening of interval, causing the contractions to occur more frequently; ergotin on the other hand did not shorten the pause, but only strengthened the individual contraction. The uterus that was under the influence of pituitrin had scarcely any pause between the pains, and could not bleed; as the hæmorrhage occurred during the interval between the contractions, contrary to what occurred in the case of ergot. From this could be deduced the advantage of pituitrin in post-partum hæmorrhage.

Amongst other things he had determined that when pituitrin was given immediately after expulsion of the afterbirth the loss of blood was only about one-third of the normal amount—i.e., as soon as the action of the pituitrin was seen in the curve the bleeding stopped. The determination of the amount of loss of blood was by Rübsamen's modified and improved method. When pituitrin was given some time before the labour the loss of blood was greater than the normal, but this could be reduced by again giving pituitrin after the expulsion of the afterbirth. He also mentioned a case of post-partum hæmorrhage from atony of the uterus in which pituitrin again did good service.

In placenta prævia the loss of blood was at once diminished after the expulsion of the foetus by the use of pituitrin. In the Dresden Frauen Klinik, pituitrin was given in the cases of Cæsarean section immediately before the abdominal incision, when the loss of blood was reduced from the usual 1,300 grammes to 8 to 900.

No real distinction could be observed between the action of pituitrin and pituglandol. Nor could any connection be seen between atonic post-partum hæmorrhage and the clotting power of the blood.

AUSTRIA.

Vienna, Oct. 19th, 1912.

SYPHILIS AND SALVARSAN.

HECHT (Prague) gives his experience of the treatment of syphilis by excision, salvarsan and mercury in a large number of cases. From 80 so treated he records the history of 50 which he has had under observation for a very long time, and gives the following results. From eight of the cases treated by excision,

salvarsan and calomel, he finds that they all remain symptomless for 16, 15, 8, 7, 6, 5 and 5 months respectively, and the Wassermann reaction was absent in all except two cases that were sometimes positive and sometimes negative. From 21 cases which had the Wassermann reaction negative 18 remained symptomless with one exception. Three recurred after ceasing the treatment in 2, 4 and 6 months respectively. Thirteen cases out of 21 which gave a positive sero-reaction after treatment of 14 and 16 months remained symptomless; in 11 of these the sero-reaction was negative. Eight cases occurred after 4, 4, 4, 5, 5, 6, 7, and 7 months, and in all but one the sero-reaction was positive. He found that the earlier the treatment was commenced the results were more favourable. With a negative commencement he found 10 per cent. out of 36 per cent. positive in recurrence. In the latter the mercury treatment was much more effectual than salvarsan, and the more intensive the treatment the better the results. Out of 26 energetically treated cases 4 only recurred, and the same may be said of those with a negative sero-reaction. In 24 indifferently treated 7 recurred. If these cases remained symptomless for eight months after the treatment is finished, with negative Wassermann's reaction we can confidently say that the abortive cure is accomplished.

After Hecht had closed, Oppenheim (Vienna) drew attention to the general reaction after the use of salvarsan in the character of erythema multiforme or erythema nodosum, sometimes assuming an inflammatory condition. He sometimes observed it in the energetic treatment with mercury, but not so often. He believed it was due to changes in the organism, and not to either salvarsan or mercury.

Marschalko recorded the case of a patient, æt. 38, into whom he injected intravenously 0.52 gramme, and who suddenly became ill with shivering, vomiting and general malaise, and on the fourth day after the injection became unconscious, with epileptic fits, and died on the fifth day. The *post-mortem* revealed punctiform hæmorrhage in the brain, especially on the surface.

NEPHRITIS.

Martin Fischer, from his researches, advances the theory of the œdema of nephritis to be due to an acid condition of the system. This he affirms to be the primary cause of the nephritis, as the acid in the organism produces albuminuria with the development of the œdema. Handovsky has shown that the œdema which Fischer represented has nothing to do with the nephritis, as the œdema caused by the acidity is local and causes a swelling of the cells. If his theory were correct that the nephritis was the cause there must be swelling of the cells in the region of the œdematous fluid, which has as yet not been proved histologically.

UNITED STATES OF AMERICA.

Washington, Oct. 12th, 1912.

THE INTERNATIONAL CONGRESS ON HYGIENE AND DERMATOGRAPHY.

THE fates favoured the meeting here of the fifteenth Congress of Hygiene and Dermography in everything but weather. Washington, the city in which the Congress was held, is one of the most beautiful cities and certainly almost the most beautiful capital of the world.

WASHINGTON, ITS BUILDINGS AND ITS PEOPLE.

It has been truly called the city of magnificent distances, and perhaps is somewhat lacking in coherence, if such a term be applicable to a city. But it is for the most part scrupulously clean, with wide streets, and, of course, being the seat of Government, with many splendid buildings. Also Washington contains a very large number of parks, the majority of which are small and would in England be termed squares. Most of these parks have many statues, some of them appear to be nearly filled with statues. Washington is distinctly a residential city, and therefore the smoke, noise, and dirt incident to the presence of factories is absent. On the other hand, there is a large coloured population: out of a population of

330,000 or so almost one-third are coloured, and, as is invariably the case when negroes are present in large numbers in a city, there are slums and many wooden houses or huts. Washington, too, like the greater number of American cities, presents glaring contrasts in architecture. For instance, the small space between the Corcoran Art Gallery and the Building of the Daughters of the American Revolution, two of the most striking and modern buildings of Washington, is occupied by a congerie of particularly mean squalid-looking huts, mostly of wood and inhabited by coloured persons. On the whole, however, the coloured inhabitants of Washington are a credit to their race. Nowhere in America, perhaps, can be seen so many prosperous, well-educated members of the coloured race, and for politeness and general good manners they have nothing to learn from white people. One blot on Washington, a blot to be observed in most American cities and towns, is the bad paving of the streets and sidewalks. Between the Capital and the Congressional Library is possibly the worst piece of asphalt paving the writer ever witnessed. Again, as a rule the sidewalks are uneven and more or less full of holes.

The fates, then, favoured the meeting in that it was held in a beautiful city, and a city in which the hotel accommodation is excellent, but it was likewise favoured because of the strong personal interest evinced in its proceedings by President Taft. The President not only made the journey from Beverley on the morning of September 23rd in order to open the meeting, but delivered an eloquent and practical speech dealing with health matters, and in addition did all in his power to render the visit of the delegates to the meeting pleasant from the social point of view.

THE ARRANGEMENTS AND COUNTRIES REPRESENTED.

The arrangements generally were very good, and supplied incontrovertible evidence that those responsible for these arrangements had used great foresight and judgment. This fact was strikingly exemplified in one detail. Books of abstracts of all the papers read were published in several languages, and what is more to the point, were ready to be given out before the first session opened. The attendance of delegates was immense, every civilised country of the world being represented. Never before, perhaps, such a galaxy of distinguished hygienists has been gathered together. Of the foreign contingents the German contingent was the largest by far, and was as great in quality as in quantity. Great Britain was well represented, while France, Austria, Italy, Russia, Norway, Sweden, Denmark, Spain, and indeed all European countries sent representatives worthy of their country and the occasion. Each country of South America furnished one or several delegates and Canada, Australia, and the British West African Colonies were represented. Among the well-known men who were present and took part in the proceedings were Dr. Karl von Noorden, of Vienna, Dr. A. C. J. Bornemann, Chief of the Medical Corps of the Danish Navy; M. le Dr. Chantemesse, of Paris, Principal Medical Inspector of the French Army, and M. Bertillon, Chef du Service de la Statistique Municipale de Paris.

Dr. Rurner, of Berlin University; Dr. Gärtner, of Jena University; Dr. Hoffmann, of the German Navy; Dr. Zahn, of Bavaria; Dr. Eugen Wurzbürger, of Saxony; Dr. Pfeifer, of Hamburg; and Dr. His, of the German Central Committee for Travel Study. Great Britain was officially represented by Dr. Arthur Newsholme, Sir Benjamin A. Whitelegge, and Dr. Theodore Thomson. Australia by Dr. W. Ramsay Smith and Dr. Walter Summons; Canada, by Dr. Frederick Montizambert, Dr. Nadeau, and Major Lorne Drum; Ireland, by Alderman Thomas Kelly and Mr. Patrick Nally; Scotland, by Sir George McCrae. The British Universities and Associations were adequately represented.

Neither the British Army nor Navy was officially represented, in contrast to Germany and France. Of the several papers contributed on naval hygiene only two were read by British naval medical officers, while

not one was contributed by an officer of the R.A.M.C.

If any criticism of the meeting can with justice be made it is that the programme was too long, not allowing time for discussion, which, after all, is the salt of such a conference.

Unfortunately, the weather conditions could scarcely have been worse. During almost the whole period of the congress rain came down persistently and pitilessly. From about eleven o'clock on the morning of the 23rd it rained for thirty-six hours without stopping, and although there were some intervals after of cessation yet throughout Pluvius dominated the situation.

(To be continued.)

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

EDINBURGH.

SCOTTISH NATIONAL INSURANCE COUNCIL.

At a meeting of the Executive of the Council held in Glasgow, the following resolutions relative to the working of sanatorium benefit, and to the provisional regulations issued by the Insurance Commissioners, have been passed:—(1) That the Executive of this Council make a strong representation to the Local Government Board for Scotland that the proposal which has been made in some places to appoint as chief tuberculosis officer the medical officer of health is opposed to the interest of tuberculous patients and the community generally, and should not be sanctioned, and the chief tuberculosis officers should be men experienced in the varying clinical manifestations of tuberculosis, who would be trusted by the profession to act in the position of consultants; that the Council further insist that patients enjoying sanatorium benefit at their own homes should have free choice of doctor. The Executive approve generally of the model scheme and scale of charges of the State Sickness Committee of the British Medical Association for treatment of tuberculosis, and commend it to all areas. (2) That the provisional regulations are not acceptable to the profession in Scotland. While admitting that they are, in the main, the logical outcome of the provisions of the Act, they serve to accentuate and render more obvious the difficulties of the medical service proposed under the Act. This Executive Committee further desires strongly to express its regret that no real attempt seems to have been made in them to satisfy the minimum requirements of the profession. (3) That it be a recommendation to the profession in Scotland to have nothing to do with the Act, as at present defined by the regulations for the administration of medical benefit." So many organisations have been formed in connection with the situation created by the Insurance Act, that it is worth while to recall the fact that the Scottish National Insurance Council represents in the fullest and most democratic way the profession in Scotland; that it possesses the entire confidence of 99 out of every 100 practitioners in the country; that it is composed of responsible, level-headed men, who have nothing to gain by opposing, for opposition's sake, the working of the Insurance Act; and that its deliberate opinion will carry in the future, as it has done in the past, immense weight in all medical circles throughout the country. Its uncompromising denunciation of the regulations as they are at present drafted expresses the very general opinion of those who have studied them in all their bearings.

MEDICAL SERVICE IN THE WESTERN ISLES.

The Highlands and Islands Medical Service Committee has recently held sittings in Skye and Lewis. In Skye it was pointed out that the doctor could not make a living by fees alone, with the result that the Parish Council had to pay a high salary ostensibly for attendance on paupers, but really to provide medical attendance not only for them but for poor non-pauper patients also. The need for better nursing, cottage hospitals, telephonic communication—the

latter especially as a means of inter-communication between doctor and nurses—was emphasised, as also was the inability of the local rate to meet the cost of these and other aspects of the problem. In the island of Lewis, the parish of Barvas, with its population of 7,000 living in hamlets along a seaboard of 27 miles, was instanced as a difficult problem. There is but one doctor, whose work is added to by the frequent recurrence of epidemics of typhus and typhoid fever among the inhabitants. All the witnesses testified to the insanitary conditions of the houses in which treatment had to be carried on, in consequence of which infections have become endemic in certain townships. It was also pointed out that the doctor rarely gets a holiday. One interesting fact which came out was that over 4,000 Lewis men were being trained for home defence in the Royal Navy Reserve, the Militia, and the Territorial Force. All the medical witnesses bore testimony to the extraordinary improvement in the health of the people, especially the children, with the change from winter to spring, and the open-air life that leads to.

THE ROYAL MEDICAL SOCIETY OF EDINBURGH.—The inaugural meeting of this Society took place on Friday last, with an address by Dr. Robert Hutchison, of London. A report of the meeting will be found in another column, under the heading of "Transactions of Societies."

GLASGOW.

THE GLASGOW CANCER AND SKIN INSTITUTION held their annual meeting on Wednesday, October 16th, Mr. Thomas Lawson presiding, and the report was adopted. Dr. H. Murray stated that in the institution 815 patients were treated during the year. During the year there had been 25 deaths, the majority of whom were patients who had been operated upon, repeatedly seeking admission to the institution; 69 patients were discharged as being well from a total of 141 treated for cancer; 10 out of 18 patients discharged well suffering from lupus; and 14 from a total of 21 patients were discharged well for tumours other than cancer; and of the remaining 635 patients with diseases of the skin and other ailments 501 were discharged well.

RECONSTRUCTION OF KILMARNOCK INFIRMARY.—The Directors of Kilmarnock Infirmary have agreed to carry out a scheme for the reconstruction of that institution at an estimated cost of £12,000. Arrangements are being made to raise the necessary funds by public subscription and otherwise, and the directorate are being advised on the remodelling of the buildings by Dr. Mackintosh and Dr. Burnett, architect, of Glasgow. A sum of £4,500 has been already promised, which includes four donations of £1,000 each from local gentlemen. To enlist the sympathies of the general ratepayers, Mr. George Clarke, one of the Directors, and Mr. William Austin, the Secretary, attended the various ward meetings held in connection with the forthcoming municipal elections, when the subject of extension was laid before the assembled congregation.

AN IMPORTANT APPOINTMENT.—Dr. Ernest Watt, M.D., B.Sc., D.P.H., Medical Officer of Health for the Burgh of Partick, Glasgow, and Superintendent of Knightswood Hospital, has been successful in securing the appointment of Chief Tuberculosis Officer for the County of Durham at a salary of £500 per annum. Dr. Watt was assistant to Professor Glaister in the Public Health Laboratory of Glasgow University, where his kindly and considerate attention was greatly appreciated by his professional brethren with whom he came in contact, and who wish him every success in his new enterprise.

BELFAST.

THE MEDICAL SCHOOL.—The winter session of the Belfast Medical School was opened last week, when lectures began at the university, and clinical teaching at the various hospitals. As far as can be judged, the entry of new students is a large one. At the Royal Victoria Hospital an introductory address was

delivered by Dr. Thomas Houston, who is head of the department for hamatology and vaccine therapy. Dr. Houston traced the rise and progress of his speciality, and showed the great influence it has had on modern medicine, and its present importance.

MEDICAL SALARIES AT THE BELFAST UNION.—The recently formed Belfast Medical Guild has boldly tackled the subject of medical salaries at the Union, and at the last meeting of the Guardians a letter was read from Dr. George Elliott, the honorary secretary of the guild, stating, first, that in the opinion of the council of that body no qualified medical practitioner should accept less than five guineas per week when acting as *locum tenens* to any dispensary appointment, and second, that the minimum salary for a qualified resident medical practitioner should be £130 per annum, with board and rooms, giving suitable accommodation for the position he holds. In support of the resolutions, he pointed out that the cost of a medical education had been more than doubled in recent years, and that the standard of education had been greatly advanced. Within the last few weeks, he added, a practitioner while acting as *locum tenens* in Belfast, paid 410 visits, vaccinated 16 children, and attended three confinements, all for the sum of £5 11s. This worked out at the rate of 2.92 pence for the visits alone, much less than a barber received for cutting a man's hair! At the same meeting a report was received from a committee appointed to inquire into the conditions of resident medical appointments under the Board, and they reported that after conference with the visiting medical officers, they agreed that in order to induce a suitable class of men to apply for these positions it would be necessary to make the positions more attractive from a professional point of view. To attain this end the committee advised that a system of rotation be adopted, so that resident medical officers would go from one post to another, so gaining wider experience, and also that canvassing for the posts should be forbidden. The question of salaries having been raised, it was decided to refer the matter to the Infirmary Committee to obtain information from other unions. No doubt the action of the Medical Guild will have an excellent effect in strengthening the hands of those members of the Board of Guardians who wish to improve the status of the resident medical staff.

DEATH OF DR. CLARKE, TEMPO.—One of the senior practitioners of Co. Fermanagh, Dr. Adam Clarke, of Tempo, died last week at the age of 67. For the past forty-four years Dr. Clarke had held the position of dispensary medical officer for the Tempo district, and he was a most popular man in the whole country around. His special interest was in the Orange Institution, of which he was a prominent and enthusiastic member.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

EXTRA-MEDICAL SYPHILIS: A REVIEWER REVIEWED.

SIR,—In your issue of October 2nd a review appeared of Vol. VI. of the "System of Syphilis." Your reviewer falls foul of Sir A. Keogh and Col. Melville. Having had the honour of association with Colonel Melville in the production of a recent paper in the *Lancet* on the subject of venereal disease, I may be excused if I enter a protest against what I consider abuse of a reviewer's privilege. He seems—if I read it aright—to imply that Sir A. Keogh's introductory remarks are traversed by Col. Melville. In fact, the two passages referred to are in entire harmony. Sir A. Keogh says (p. 19):—

"If the C.D. Acts were successful they might be justifiable, degrading as the execution of the provisions must be to the police who have to enforce them, and the medical men who have to carry out the examination they prescribe. That they are not successful the experience of the Continent proves. . . . For good or for evil, Great Britain has taken

up the line that there shall be no invidious regulation, discriminating against one sex only, where both are equally guilty, . . . and no discrimination between rich and poor. . . . That the decision has been taken for good, I steadfastly believe. We can point to the statistics of our army to prove it."

The statement is one of fact; the opinion may be right or wrong, but it is entirely free from cant or prudery. . . On p. 40 Col. Melville says:—

"At least it is certain that the young British soldier is not naturally five times as immoral as the German of the same age, or six times as wicked as the young Bavarian. There are two possible explanations: (1) England and America are the only two great countries where some form of C.D. Act or other is not in force; (2) they are the only two nations which still rely upon the voluntary method of recruiting, with its natural corollaries of greater leisure . . . and higher pay."

Your reviewer quotes (1) as if it were accepted by Melville as the cause of the greater prevalence in the British Army, whereas in fact Melville rejects it in favour of (2).

Melville is taken to task for objecting to the system of distributing "prophylactic kits." Does the critic approve the method? To my mind it is both shortsighted and revolting. It is ruinous to the self-respect of the men who receive or distribute them, and of the officers who teach their use. To your reviewer such a moral attitude is foolishness; yet ethical considerations are necessarily bound up with any statesmanlike view of the problem of venereal disease. No blame to the doctor who sticks to his doctoring; but no blame either to the doctor who wishes to be a statesman too.

But I suspect that your reviewer, like many others, in and out of the medical profession, has a secret hankering after the Continental method of State regulation of vice. Some such enactment, they think, would in time exterminate venereal disease, if only British prudery would cease from troubling. Let those who hold this view study Co. Melville's army statistics for the last 70 years; let them read the accounts of the Brussels Conference of 1899 and 1902, with Professor Gailleton's summary verdict on State regulation: No good at all. If State regulation be a good thing for the nation, let them come out into the open and unfold its virtues; it has had trial for 100 years and ought to have something to show.

What, the reviewer asks, has Sir A. Keoghs' criticism of the C.D. Acts got to do with the prevention of V.D.? Every thing. The C.D. Acts were passed exclusively with this object. They failed; and yet a discussion of their failure is irrelevant!

No system of syphilis can be complete without explaining and appraising the various methods which have been devised to rid society of the scourge. This is what Col. Melville has done, at least with some success.

The cobbler to his last; the doctor to his microscope; the clergyman to his Bible; the reviewer to his review. Yet righteousness, cleanness and truth are the affairs alike of all.

I am, Sir, yours truly,
DOUGLAS WHITE, M.D.

Harrow-on-the-Hill,
October 21st, 1912.

[We have referred to the review alluded to by our correspondent and fail to trace in it any abuse of the legitimate functions of a reviewer. The writer enters a strong protest, it is true, against the introduction of non-medical phases of the subject in a purely medical book. We agree with him in thinking it best in such a work to avoid the discussion of highly controversial ethics that lie outside the immediate professional sphere of labour.—ED. M.P. and C.]

THE MEDICAL SOCIETY OF LONDON AND
PROFESSOR TH. KOCHER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

We have been asked by the honorary secretaries of the Medical Society of London to give space to the following letter, which we gladly do:—

The following letter has been received by the Medical Society from Professor Th. Kocher, in reply to an address of congratulation from the Society on the occasion of the celebration of his forty years' professorship at the University of Berne.

To Dr. Mitchell Bruce, President of the London Medical Society and Members.

Dear Mr. President and Gentlemen,—It was a pleasant surprise to receive the address handed me by your distinguished representative, on the occasion of the jubilee of my forty years' professorship, and it will always be to me a most valued possession.

Your society was one of the first to recognise the importance of my publication on the Thyroid Gland, and one of the first to confer upon me the Honorary Fellowship at a time when I had little reason to be well known, and it is for this I owe you my warmest thanks.

May your society, whose efforts are directed in such an eminent and influential manner, continue to flourish to the advancement of medical knowledge and to raising the standard of the medical profession.

Please accept, Mr. President, Officers and Council of the London Medical Society my most cordial thanks, and assuring you of my respect and esteem.

Yours truly,
(Signed) TH. KOCHER.

P.S.—To Professor Sir Victor Horsley, who came so far to bring me the address and to greet me on my anniversary, I owe my personal thanks.

NATIONAL INSURANCE REMUNERATION—A WARNING.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The *Times*, in announcing the publication of the regulations framed by the Insurance Commissioners, points out that they are of a technical character, and states that the remuneration which the Government is willing to pay per head is not announced. Therein lies their snare!

Upon referring to Clause 28 it is apparent that any figure which may be announced is not the amount which the doctors will actually receive. On the contrary, the pooled capitation fees will have to bear large deductions before they will be available for the purpose of medical remuneration. These deductions fall under three heads:—

- (a) For drugs and appliances;
- (b) For mileage;
- (c) Cost of medical benefit for insured persons who are away from home.

The charge under (a) must be a heavy one. The chemists are to charge according to each item (which is right and proper), and it is unlikely that the sum required per head will be less than about 3s. 6d., which is the figure arrived at by comparison with twenty-five years of German experience.

For mileage a varying sum must be set aside, a small proportion for a county borough, and a large one for a sparsely populated and scattered area.

The charge under (c) would depend upon the nature of the population, and would vary considerably.

In addition to these it is clear that there would be other charges on the fund for the special services as defined in Schedule 1, part 2; and for those beyond the competence of an "ordinary practitioner." (Schedule 1, part 1, section 2.) These would include laboratory investigation, for which no other provision has been made.

Deduct the charges for all these items from the agreed capitation fee, and there remains the sum available to pay the doctor. Could any arrangement be more unsound?

I am, Sir, yours truly,
J. WEBSTER WATTS,
Secretary, National Medical Union.

THE POSITION OF DENTISTRY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your correspondent, "An Interested Observer," cannot have read my letters with sufficient

care. They are perfectly clear, and I do not think I ought to take up your valuable space by repetition of their facts and arguments. The only unregistered practitioners who can practise dentistry in what your correspondent calls an "ethical" fashion are such as make known unequivocally to all their customers that they lack any legal qualification. It will be hard to produce many who do this. They nearly all pretend to be legally qualified, and the worst pretenders are the unscrupulous quacks who are out only for plunder. The mischief wrought by those who may be merely ignorant is well illustrated in the letter by my old pupil, "A Country Dentist," in your last issue. Cases such as he relates exist by the ten thousand among the less wealthy and the poorer classes. The practice of dentistry by the class of practitioner whose cause "An Interested Observer" champions is inflicting serious injury upon the public health; it is largely both fraudulent and cruel, and ought to be put an end to. If dentistry were properly protected there would soon be a great influx of qualified men, and it would be possible to institute a State service under the Insurance Act, or by means of provident dispensaries. Practice under false pretences for years unchecked in consequence of failure of legislation intended to prevent it, does not constitute any vested interest or valid claim to protection, and when new legislation is constituted it should become impossible for any save truly "ethical" practitioners to assume titles, or in the remotest way pretend to hold a professional position. This, I may repeat, has been done for the lawyers, it has been done for the veterinary surgeons; it can be done for doctors and dentists.

I am, Sir, Yours truly,
A HOSPITAL DENTIST.

October 17th, 1912.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Whilst thanking you for the service you are doing to our cause by publishing this correspondence, and your excellent editorials anent it, I would like to express my opinion that the views of "A Country Dentist" are somewhat pessimistic with regard to the prospects of men entering upon the practice of dentistry. If masters of their work and really good operators, which I agree with "A Country Dentist," is the most important thing of all, and if they have tolerable personal qualifications, without which failure must often overtake them, I think the young dentist starting in life has a chance as good as that of the average medical practitioner of making a decent livelihood. He must take care not to start where there are already too many qualified men in the field. He has the immense advantage nowadays of being received as a professional brother by medical men whether he possesses merely a dental diploma or a full qualification. And it needs the support only of one or two family doctors in fair practice to set the young dentist going. No advertisement can be so good as the recommendation of a doctor. In no branch of practice does the patient more easily recognise the good he has got from clever services than in dentistry. Nearly every patient made comfortable becomes a walking advertisement. There is not a supply greater than the demand for good dentistry; more and more are the intelligent public learning to appreciate it. I agree with your correspondent and sympathise with him with regard to the question of social status. A medical man, a "doctor," is accepted in society as an educated gentleman, and can maintain that position if he has real personal claim to it. It matters not whether or no a dentist has the highest qualification, such as F.R.C.S. or a University degree, he comes on the social scene as a mere dentist, and is in danger of being looked at askance as one of the gentry whose show cases of artificial teeth adorn shop windows in the High Street, and whose illiterate, mendacious advertisements appear in the local papers, and it is not always easy to live down consequent prejudice. Protection by law would do much to redress this grievance and to induce more men of sensitive character to join the speciality. I agree with all those who maintain

that it is of far greater importance to the public than the profession that medical laws should be made efficient in every department in accordance with the intention of the legislature; and if called upon to give evidence in a Government inquiry I could add my testimony to the facts with regard to the injury and suffering now being inflicted upon the poorer classes by the ignorant and unscrupulous practitioners to whose mercies they are mostly left. It is to be hoped that the Select Committee on quack medicines now sitting may be followed by one on unqualified practice, and that dentistry will be included. This seems to me the necessary preliminary to new legislation. The freedom with which your correspondents have expressed their opinions is, I am in some degree sure, due to the fact that you have allowed them to veil their identity. I enclose my card and beg to be allowed to subscribe myself

Yours truly,
ANOTHER COUNTRY DENTIST.

October 18th, 1912.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The position of dentistry is precisely the same as that of the whole medical profession of which it is a legally constituted branch. The clauses of both Medical and Dental Acts specifically devised to confer some scant privileges upon qualified practitioners, and to safeguard the interests of the public against fraudulent imposture have been declared impotent for their purposes by the supreme Court of Law. In giving judgment the Courts have on several occasions expressed regret that they were constrained to interpret the Acts in accordance with their letter rather than their obvious spirit. The whole lamentable situation seems due to the bad drafting of the Acts, and its long continuance to the lethargy of the Medical Council, and the apathy of the profession. Inspired by a kind of lofty altruism, the whole medical profession has, to a very great extent, left its worldly interests to take care of themselves. The legislature has accordingly always paid little regard to those interests, and, for example, in the Insurance Act, has treated medical men like so many sordid hucksters rather than members of a true profession living as a mass up to a high ethical standard. This attitude of the profession has unfortunately led to the creation or aggravation of evils which are inflicting grievous injury upon the public, and, if only for the sake of the public, it is surely time that an effort were made at least to establish and force to the front the full case for medical law reform.

I am, Sir, yours truly,
G. S. B.

Manchester, October 12th, 1912.

OBITUARY.

DR. ANDREW DUNCAN, OF LONDON.

WE regret to announce the death of Dr. Andrew Duncan, of Chester Street, Grosvenor Place, S.W., which took place on the 18th inst., at a nursing home, aged 62. The deceased, who was the son of the late James Duncan, M.B., qualified as M.B.Lond. in 1874, taking gold medals in medicine and midwifery, studying at King's College, London. He obtained the gold medal in surgery at the B.S. in 1875, becoming M.D. in the same year. He took the F.R.C.S.Eng. in 1877, and was elected F.R.C.P.Lond. in 1907. Dr. Duncan had a most distinguished career at King's College, where he was House Surgeon and Surgical Registrar. Afterwards he held similar appointments at the Seamen's Hospital, Greenwich, and at the Public Dispensary, Carey Street. In 1872 he obtained the post of Medical Registrar of Charing Cross Hospital, and two years later he became Medical Tutor and Pathologist at St. Mary's Hospital. He soon began to interest himself in tropical diseases, joining the Indian Medical Service, of which he was late Lieut.-Colonel in medical charge of the 2nd Battalion 2nd (R.E.O.) Goorkha

Rifles. On returning to England he became Physician to the Westminster General Dispensary, subsequently accepting the post of Physician to the Seamen's Hospital and Lecturer in Tropical Medicine at the London School of Tropical Medicine. He also lectured upon this subject at the Westminster Hospital, and was an Examiner at the University of London. In 1886 he published his "Prevention of Disease in Tropical Campaigns" and "Guide to Nursing in the Tropics." He also contributed numerous articles on tropical diseases to Quain's "Dictionary of Medicine," as well as to the medical journals.

DR. WASHINGTON EPPS, OF LONDON.

THE death took place last week, at his residence in Wellgarth Road, North End, Hampstead, of Dr. Washington Epps, of Queen Anne Street, W., in his sixty-fifth year. The deceased, who qualified as L.R.C.P. Edin., and M.R.C.S. Eng., in 1871, received his medical training at University College Hospital. He was well known in homœopathic circles, and he was consulting physician to the London Homœopathic Hospital, a Fellow and late president of the British Homœopathic Society, and was formerly medical director of the Royal Jennerian Vaccine Institute. He was a man of strikingly handsome appearance, of which studies had been made by several well-known artists, including the late Sir Lawrence Alma-Tadema. Dr. Epps was the subject of Sir Lawrence's popular portrait picture, "My Doctor," exhibited at the Royal Academy in 1887. He was brother of the late Lady Alma-Tadema and of Mrs. Edmund Gosse. He was the author of a work on skin diseases, which reached its fourth edition, and contributed several articles to medical journals.

MR. W. INNES ADDISON, GLASGOW UNIVERSITY REGISTRAR.

MR. WILLIAM INNES ADDISON, Registrar of Glasgow University, died, aged 55 years, suddenly at his residence, 2 Florentine Place, Hillhead, Glasgow, on Tuesday night, October 15th, and was interred in the Western Necropolis on Friday, October 18th. Until a few days before his death, Mr. Addison appeared to be in his usual health, and though at the beginning of the week he was not feeling well the symptoms were not regarded as serious. On Tuesday afternoon he left the office at the University at five o'clock, taking with him some work to do at home, but died late the same evening. Mr. Addison was born in the parish of Brechin, and after early school days, studied law at Edinburgh University and Arts at Glasgow. He served his apprenticeship in Brechin and then went to Edinburgh as a clerk, afterwards coming to Glasgow in the same capacity, and in 1881 was admitted a Notary Public. In 1887 he was appointed assistant clerk of Senate of Glasgow University, and in 1905 he became Registrar of the General Council, which offices he held conjointly until 1911, when he became Registrar of the University. Mr. Addison took a keen personal interest in his duties and in all matters pertaining to the University, and published several works which are of great value as books of reference, which include a Roll of Graduates of the University of Glasgow from December 31, 1727 to December, 1897, with short Biographical Notes, 1898, and the Snell Exhibitions from the University of Glasgow to Balliol College, Oxford. At the time of his death he had practically completed "The Matriculation Albums of the University of Glasgow from 1728 to 1858," a volume containing a verbatim transcription of the matriculation albums for the period mentioned. He also contributed numerous articles and sketches to various periodicals and newspapers.

To all students of Glasgow University both past and present, the news of his death will have come with a tragic suddenness and will carry with it a sense of personal loss.

Dr. T. B. MORIARTY, CORK.

WE regret to note the death of Dr. T. B. Moriarty of Cork, which took place on the 15th inst., at the age of seventy-five. Educated at the Queen's College,

Cork, and Trinity College, Dublin, he obtained his M.D. in 1860, and shortly afterwards entered the Army Medical Service. He served with Lord Wolseley in the Ashanti and other African campaigns. He retired nearly thirty years ago, and has since practised in Cork, where among other appointments, he held the posts of surgeon to the Cork Prison, and physician to the Cork Fever Hospital. He was held in much respect, not only in Cork, but throughout the south of Ireland.

MR. G. F. BLAKE, DUBLIN.

THE sudden death occurred recently of Mr. G. F. Blake, J.P., for many years Registrar of the Royal College of Surgeons in Ireland. In his younger days, Mr. Blake was associated with the late Dr. Jacob in the conduct of this journal, but the greater part of his life was spent in the service of the Royal College of Surgeons. His official duties brought him into contact with many generations of medical students. By them, as by the Council of the College, he was held in the highest respect, and on his resignation last year he received many good wishes for a prolonged and happy life.

SPECIAL REPORTS.

REPORT ON ISOLATION HOSPITALS. (a)

THIS report gives the results of an inquiry completed in 1911, into the cost of construction of isolation hospitals. It may be regarded as a supplement to the late Sir Richard Thorne Thorne's report of 1882 which was reprinted in 1900 with a preface, giving information up to that date, and it includes detailed comparisons of some two dozen isolation hospitals of various sizes.

The first thing we note is that these hospitals are expensive necessities. Their constructional cost works out at an average of £400 per bed for a hospital of medium size, while in certain cases £800 has been exceeded, and this cost is increasing on account of the higher price of labour and materials and the desire of local authorities to provide more efficient accommodation. The higher extremes of cost are due to one or more of several factors. The hospital is often a small one—one bed per thousand of the population is a rough working estimate—and in such a case the total cost is divided among a very few beds. The selection of the site presents grave difficulties. The erection of an isolation hospital is objected to on grounds of sentiment, fear of infection, or depreciation in value of neighbouring property. These factors limit the authorities in their selection, and force them to give an enhanced price, or to buy a site much larger than is necessary. When the site is obtained it may be remote from sewers, water and light, and the expense of supplying these and often of making roads and carting materials adds greatly to the constructional cost.

The report emphasises the importance of small districts combining for the purpose of building an isolation hospital with the advantages of economy in avoiding duplication of a site, fencing, water supply, and administrative buildings, and of facilitating the classification of patients in respect of the diseases from which they may be suffering.

As isolation hospitals are regarded primarily from the point of view of sanitary defences, and as their functions of relieving sick individuals and of freeing the public from the loss and inconvenience consequent on the retention of an infectious case in a house or institution are held to be of much lesser importance, it follows that such a hospital must be kept in constant readiness, for if preparation has to be made on the discovery of an outbreak of infectious disease the time when the hospital would have been of most service is past.

The report is clear, adequate, and interesting, and

(a) "Supplement in continuation of the Report of the Medical Officer of the Local Government Board for 1910-1911, containing a Report on Isolation Hospitals by H. Franklin Parsons, M.D." H.M. Stationery Office. 1912. Price 1s. 7d.

lays down in no uncertain voice the requirements of the Local Government Board on all questions that may concern a local authority which contemplates the provision of accommodation for coping with infectious disease.

MEDICAL SERVICE IN THE SCOTCH HIGHLANDS.

Our Edinburgh Correspondent has briefly referred in another column to the difficulties attending Medical Service in the Highlands and remote islands of Scotland. Below we have pleasure in publishing a fuller description from another correspondent on the spot, which we think will be read with interest:—

The difficulty of obtaining medical aid in this out of the way Isle has been somewhat stimulated by a visit paid to the west side of the island on the 12th October by the Highlands and Islands Medical Service Committee for the purpose of taking evidence at Garrynahine from witnesses who represented the parish of Uig. This extensive parish, which is cut up by long arms of the sea, and in parts very rough and mountainous, has only one doctor for 4,500 inhabitants, and of these 700 are resident in the remote island of Bernera. Dr. Victor Ross and Mr. MacDonald, chairman of the Parish Council, along with other residents, very clearly set before the Committee the great difficulty of providing efficient medical attendance under such circumstances.

On Monday, October 14th, another meeting of the Committee was held in Stornoway, at which witnesses were heard from the parishes of Lochs and Barvas. Amongst those who gave evidence was Dr. Cameron, Lochs; Dr. Ross, Barvas; and Mr. Smith, chemist, Stornoway. Lochs from its geographical position presents difficulties quite as formidable as those of the parish of Uig, with a much larger population depending on one doctor. The parish of Barvas has a population of nearly 7,000, who live in hamlets scattered along a seaboard of twenty-seven miles, and there is but one doctor. To add to the difficulties of this parish, and which applied more particularly to this parish, was the frequent recurrence of typhoid and typhus fever, which in recent years has been a heavy burden on the medical attendant.

All the witnesses testified to the unsatisfactory conditions as to housing and sanitation under which medical treatment had to be carried on, and to the necessity of improvement in these conditions as a preliminary to the effectiveness of any medical provision. It was shown that in some of the townships infectious diseases had become endemic. In the evidence it was proved that the medical attendant rarely gets a holiday, which was detrimental not only to himself, but also to the people he served.

The medical witnesses gave evidence of the extraordinary improvement in the health of the people with the advent of spring and summer, and in the case of the children more particularly with the change to life in the open. In the case of the children there was evidence in recent years of physical deterioration, which in part could be ascribed to underfeeding, to the use of artificial foods, and to indulgence in over-brewed tea, which also affected their elders.

From the evidence it is apparent that there is urgent need of educating the mass of the population to realise the value of medical attendance in the early stages of sickness and disease and of systematic care in personal and household hygiene.

On Wednesday, October 16th calling at Harris, two local doctors and members of the local public bodies were examined as to the medical wants of that district, and continuing the inquiry at Lochmaddy, North and South Uist, where some of the witnesses were in favour of the compulsory levy of a medical rate locally.

The Procurator-Fiscal for Long Island, Mr. Chisholm, who had intimate acquaintance with the island through a thirty years' residency, thought the present medical service was inadequate, but that the locality was too poor to stand heavier rating than at present. Mr. Chisholm favoured for the Outer Hebrides a State Medical Service, the medical man being controlled

from some central authority, who would have a voice in the appointments of medical men and their holding of office, and should also rigidly supervise their conduct. After a few years' service in the islands they ought to be promoted, according to merit, to more desirable posts elsewhere.

Mr. Wilson, Subland Commissioner, said that the people generally would be able to pay 5s. a family towards medical aid, that he had worked such schemes in two parishes, and that the people could not pay much more.

REVIEWS OF BOOKS.

DEFORMITIES. (a)

No issue of this year will be more welcome to the general surgeon or orthopaedic specialist than the second edition of "Tubby's Deformities and Diseases of the Bones and Joints." It is now 16 years since this work first appeared, and therefore it has been necessary that the new edition should be entirely rewritten and rearranged. It is extraordinary how, in spite of this delay in keeping the book up-to-date, the first edition has for so long retained its place as one of the few standard works on Orthopaedics.

Since 1896 our knowledge of deformities has expanded its former boundaries to include all the morbid conditions that lead to the deformities of bones and joints. On this account Mr. Tubby treats his subject in a modern way as the surgery of the entire locomotor apparatus.

The result of his work is in these two volumes, which contain a most adequate account of the modern surgical treatment of all deformities, with full discussions of the opinions of the leading bone surgeons. The practical value of the book is increased by numerous clinical records of unusual cases and by a full reference list of authors and papers.

After reading the book one must be glad that such a careful and complete reference is available. Its title is not belied by its contents. After the average book of the sort that merely serves to air the few and well-worn originalities of its author, this one stands out unmistakably the work of a master.

Messrs. Macmillan are to be congratulated on the formation of the book. The illustrations are of great help, and we have never seen better plates of X-ray pictures. The book should certainly be added to the library of every surgeon interested in the most interesting and difficult branch of surgery with which it deals.

LITERARY NOTES.

THE distinguished author of "Methods of Air Analysis," Dr. J. S. Haldane, LL.D., F.R.S. (London, 1912. Charles Griffin and Co., Ltd.), is admirable in the way he deals with a tricky subject. He spares no pains to detail at length sources of error and requirements for accuracy. His subject owes very much indeed to his research and his descriptions of the methods of analysis of atmospheric, mine and expired air and of blood gases, are worthy of the research that preceded them.

* * *

THE success of Prof. Dieulafoy's "Text-book of Medicine" appears to be phenomenal in the domain of medical literature. Fifteen editions of the original work in French were sold by the middle of June, 1910, when an English edition was first published by Messrs. Bailliere, Tindall and Cox. This, we are informed, has met with even a more pronounced success; so great, indeed, has been the demand, that the publishers have found it necessary to reprint no less than three times within a period of eleven months.

(a) "Deformities, including Diseases of the Bones and Joints." A Textbook of Orthopaedic Surgery. By A. H. Tubby, M.S. Lond., F.R.C.S. Second Edition. Illustrated by 70 Plates and 1,000 Figures. Pp., Vol. I., 823. Vol. II., 807. Two Volumes. London: Macmillan and Co. 1912. Price 45s.

They now announce a second edition as "ready this day," making 17,000 copies issued in two years. We have just seen the new edition, in which the Editor and translators state that every chapter has been revised and the newest material added. It is published in two handsome volumes, and is illustrated with nine coloured plates in the text.

* * *

DR. VAUGHAN BARBER has written a brochure on "The Tuberculin Treatment of Consumption" (London: Nisbet and Co. 1912), which is designed to give tuberculin "its rightful place in the English armory." Having given a brief sketch of the principles on which tuberculin treatment is based, the author degenerates into indiscriminate eulogy of the work done at Dr. Camac Wilkinson's dispensary in Kennington. The merits and the flaws in Dr. Wilkinson's methods are equally lauded. "One of the most significant features of this treatment is that it can be carried out on patients whose environment remains unaltered—the mother is not taken from her nursing child, the breadwinner is not taken from his daily work." The tuberculin treatment gives, as we know, excellent results in suitable cases. It more general use is being hindered by ill-judged and indiscriminating advocacy.

* * *

THE number of tracts on medical subjects, written for lay readers, is rapidly increasing, and there is no doubt that the lay public requires sound information on many medical subjects. It is no easy matter for an author to decide what it is proper to say, and what it is better to omit, and the author who succeeds in the task is entitled to our gratitude. We are glad, therefore, to welcome two booklets dealing with the subject of consumption, both of which are well suited for the instruction of the lay reader. In "Consumption: Treatment at Home and Rules for Living" (3rd edition. Bristol: John Wright and Co. 1912. Price 1s. net), Dr. Warren Crowe gives a series of rules of conduct for patients undergoing treatment for consumption at their own homes. The book is intended to be given by practitioners to their patients. The rules are well chosen and clear, and the author has made them more effective in claiming obedience by giving the reasons for each rule. Each appears, therefore, as the termination of a definite argument. "The Problem of Consumption," by "A Birmingham Physician" (London: Headley Brothers. Price 1s.), is of somewhat different scope and intention. A portion of it appeared first in the pages of *One and All*, the magazine of the Adult School Movement. It appears to be intended, not unsuccessfully, to give the general reader a sketch of the extent, nature, and pathology of consumption, and the methods adopted to prevent its spread and to combat infection. The anonymous author conveys much sound information in an interesting manner.

MEDICAL NEWS IN BRIEF.

Peamount Sanatorium—Question of Water Supply.

IN the House of Commons last Wednesday Sir John Lonsdale asked the Chief Secretary if he was aware that although thousands of pounds of public money were being spent by the Women's National Health Association upon the Peamount Sanatorium, the water supply of the place had been found to be insufficient in quantity and unfit for dietetic purposes; would he state who was the Medical Inspector of the Local Government Board who inspected the site and reported it to be suitable for a sanatorium, and why the inspector did not satisfy himself that there was a sufficient supply of pure water for a large institution before recommending the site; would he state approximately how much money had been spent in endeavouring to find water at Peamount, and whether he now considered that this sanatorium was fit for the reception of patients, seeing that all drinking water had to be carted a distance of two miles?

Mr. Birrell: The Peamount site was selected by the Women's National Health Association after it had been examined and favourably reported upon by a well-known Dublin firm of architects and sanitary engineers, and subsequently inspected by three eminent Dublin physicians, who endorsed and confirmed their report. The Local Government Board were not asked to send a medical inspector prior to the decision to select the site, but ever since the actual commencement of the works of construction these have been frequently inspected by two officers of the Local Government Board, and no payments from public funds have been made except after being duly submitted to the Board and authorised thereby. The water supply, on investigation, is found unsuitable for dietetic purposes, but the sinking of a well which will yield, it is believed, an adequate supply of water for all purposes is now progressing. The sanction of the Local Government Board to the opening of the institution as a whole will be given when a thoroughly satisfactory water supply for a large establishment of the kind has been obtained, and not before, but owing to the urgency, which was the primary consideration, for the establishment of sanatoria, the Board inspectors have felt justified in recommending that during the sinking of the well a limited number of patients should be admitted, for whom a supply of drinking water of the most excellent quality can be provided from a spring outside the property, the necessary arrangements having been made for this purpose. I am informed that the expenditure incurred in connection with the water supply at present is well under £200.

Sir J. Lonsdale: At what distance is the spring from the sanatorium?

Mr. Birrell: About two miles.

Sir J. Lonsdale: Why did the Local Government Board not get their own Medical Officers to report on the water supply before authorising the grant?

Mr. Birrell: The site had already been properly examined to the satisfaction of the Local Government Board by experts in Dublin.

The Imperial Medical Reform Union.

AT a recent meeting of the Imperial Medical Reform Union the following resolution was unanimously adopted after considerable discussion:—"That the Council of the Imperial Medical Reform Union acknowledge, with thanks, the courtesy of the National Insurance Commissioners in supplying them with advance copies of the Provisional Regulations for the administration of the medical benefits under the National Insurance Act, but notice with regret that in Sec. 28 the Insurance Commissioners should have relegated the medical profession to a subsidiary position as regards remuneration, especially as it is only with their aid that the Act can be carried out and made a success."

Among other avowed objects the Union advocates a one-portal system, hospital reform, contract practice on basis of payment for work done, the suppression of quackery, and the appointment of a Minister of Public Health in the Cabinet.

The British Red Cross Society.

THE first surgical "unit" raised by the British Red Cross Society for service in the war left Victoria on Sunday last for Montenegro. The "unit" consists of three dressers and twelve orderlies. Surgeon-General Bourke, as director, was in charge and the other surgeons were Dr. Anthony Bradford, late resident medical officer at St. Thomas's Hospital Home, Dr. F. Goldsmith, of Adelaide, Australia, and Surgeon-Captain Martin-Leake, V.C. The "unit" has been selected, equipped, and despatched by the Medical Relief Sub-Committee of the society in four days. Their destination is Cetinje, where they will arrive on Thursday.

Three further "units"—the cost of which is being paid by Sir Ernest Cassel—will be sent to Turkey on Friday next. Sir Frederick Treves also stated last night that, notwithstanding the poor response to the public appeal on behalf of the Balkan Relief Fund,

the society hoped to be able to comply with the urgent requests from Greece for surgical aid.

The Lady Mayoress has arranged for a subscription ball to be held at the Mansion House on Thursday, November 7th, in aid of the British Red Cross Balkan Fund.

The British Red Crescent Society is organising a field hospital for Turkey consisting of surgeons, assistants, male and female nurses, with full equipment, and hopes to despatch it before the end of the week.

X-Rays for Consumptives.

At the last meeting of the Executive Committee of the Borough of Poplar Dispensary for the Prevention of Consumption, a resolution was passed to instal a complete up-to-date X-ray apparatus for the examination of the chests of consumptive patients.

Medical Fees for Tuberculosis Treatment.

THE Surrey County Insurance Committee have obtained the approval of the National Health Insurance Commissioners to a scale of payments to doctors for work in connection with the treatment of tuberculous patients. The scheme provides for a payment of 5s. for each medical report, Form 2, 2s. 6d. for each visit to patient, and 2s. for each attendance at the surgery, these two payments to include ordinary medicines. It is also recommended that tuberculin be paid for as an extra in each case where it is certified as necessary; that 2s. 6d. be paid for each injection of tuberculin in addition to the ordinary attendance fee; that 5s. be paid for each night visit certified to be necessary between 8 p.m. and 8 a.m.; and 5s. for each quarterly or special medical report required by the Local Government Board.

The York Medical Society.

THE inaugural address of the ensuing session of the York Medical Society was delivered on the 12th inst., in the new theatre at the Yorkshire Philosophical Society's Museum, by Dr. S. Monckton Copeman, F.R.S., who took for his subject the connection between house flies and disease. Dr. Godfrey, president of the York Medical Society, was in the chair, and there was a large attendance, and amongst those present were Dr. Goode, Dr. Evelyn, Dr. E. M. Smith (Medical Officer for York), Dr. Micklethwait, Dr. Mills (Easingwold), Dr. Draper, Dr. F. Turner, Dr. Sanderson Long, and many other members of the Association and their friends.

The annual dinner was held subsequently at the Station Hotel, York, when a large and representative gathering assembled in honour of the orator.

The Royal College of Surgeons of England.

THE new calendar of the Royal College of Surgeons has been issued by the council for the year 1912-13. The fellows now number 1,562, an increase of over forty compared with last year, and include 1,526 who obtained the qualification by examination. The members' list contains 17,062 names, an increase of upwards of 100, while the list of licentiates in dental surgery has also considerably augmented. One lady, Miss Davies Colley, obtained the fellowship by examination during the year, and was the first of her sex to attain the honour. There are now five women on the roll of members, and three hold the diploma in Public Health. No lady student has, as yet, obtained the college diploma in dental surgery. Dr. Peter Redfern, of Belfast, is the oldest fellow, and Surgeon-Major H. B. Hinton, of Glenelg, South Australia, the oldest member.

Dublin Guardians and the Medical Profession.

THE following resolution was passed by 16 votes to 7 at the last meeting of the local Dublin Guardians:—
"That in consequence of the action of the Dublin Medical Committee in refusing medical attendance to members of friendly societies, or other such bodies, and excessive demands made by that Committee, and the undue hardships which will operate on the thrifty workers of the city, it is hereby directed that a notice be inserted in the newspapers, and hung up in the various dispensaries, intimating the hours of attend-

ance of the doctors, morning and evening, also the name and address of each guardian and warden from whom tickets may be obtained, and the conditions of same.

"That the Master of the Union be directed not to permit any bodies from this Union to be sent to the Colleges or Schools of Anatomy, but that in future he sees that all unclaimed bodies are buried.

"That all doctors in the employment of the Guardians or medical officers who are in receipt of a superannuation be communicated with to ascertain if they are assisting the Dublin Medical Committee in their cruel medical boycott, and that the Clerk be directed to have legal opinion as to whether such scheme of superannuations may be cancelled, seeing that the action of the Dublin Medical Committee will necessitate a large number of patients being rejected by the various hospitals, being sent to the workhouse, and the consequent increase in the rates of the city.

"That we request the Irish Members of Parliament to at once have defined the Medical Act of 1858, and, if necessary, its amendment. Copies of this resolution to be sent to each of the medical officers under this Union, and to the Members of Parliament representing the county and city."

The After Care of Recovered Patients Discharged from Insane Asylums.

LADY BATTERSEA has kindly placed Surrey House, Marble Arch, W., at the disposal of the Ladies' Guild connected with the After-Care Association for poor patients discharged from asylums, on Thursday, October 24th, from 2 to 7 p.m., when a café chantant and model market will be held. The proceeds are in aid of the funds of this decidedly useful Association, which is badly in need of funds. Tickets purchased beforehand, price 2s., may be obtained from the Hon. Secretary, Mrs. Ironside Bruce, 10 Chandos Street, Cavendish Square, London, W., or tickets purchased at the door 2s. 6d. The services of a number of well-known artistes have been secured, and the market will be of an attractive character.

Royal College of Surgeons of Edinburgh—Fellowships.

At a meeting of the Council of the College last week the following gentlemen, having passed the requisite examinations, were admitted fellows:—George W. Bury, M.B., Ch.B.Vict.; Robert G. M. Clements, M.B., Ch.B., M.D.; James G. Cormack, L.R.C.S.E. (Triple Qual.); Arthur Fells, M.B., C.M.Edin.; Howell W. Gabe, M.R.C.S.Eng., L.R.C.P.Lond.; Norman J. Gerrard, M.B., B.S.; Arthur C. Hendrick, M.B.Univ.; Corrie Hudson, D.S.O., M.R.C.S.Eng., L.R.C.P.Lond.; John W. Illius, M.R.C.S.Eng., L.R.C.P.Lond.; Fritz Kahlenburg, M.R.C.S.Eng., L.R.C.P.Lond.; Vaughan Lloyd-Evans, M.B., Ch.B. Edin.; Ronald B. Macfie, M.B., Ch.B. Edin.; Alexander McMurray, L.R.C.S.E. (Triple Qual.); Leonard Myer, M.R.C.S.Eng., L.R.C.P.Lond.; Charles T. H. Newton, M.B., Ch.B., M.D. Edin.; Gerard F. Porter, M.B., Ch.B., M.D.; William Russ, M.B., Ch.B. Edin.; William E. Scott-Moncrieff, M.B., C.M., M.D. Edin.; Arthur A. Straton, M.R.C.S.Eng., L.R.C.P.Lond., M.B., Ch.B. Lond.; Leonard W. O. Taylor, M.B., Ch.B. Edin.; William S. Thacker, M.B., Ch.B., M.D. Dub.

Glasgow University.

The following degrees have been conferred. The graduates included three ladies, who received the degrees of M.B., Ch.B. Three students passed M.B., Ch.B., with honours, four with commendation, and 36 obtained ordinary degrees:—

Bachelor of Medicine and Master of Surgery (M.B., C.M.).—John J. Lowell, L.R.C.P., etc.

Bachelors of Medicine and Bachelors of Surgery (M.B., Ch.B.), with honours.—James H. Robertson (who also gained the Burton Memorial prize for the most distinguished graduate in medicine of the year), Thomas Martin, James H. Dible. With commendation.—William B. Drummond, William F. Wood, Samuel Blumenfeld, Charles Brash, Adam Brown, William Brown, John S. Buchanan, James

W. Burton, John H. J. V. Coates, Jane M. Davidson, James H. Dible, John Dickie, William B. Drummond, John M. Forsyth, John E. Fyfe, Alexander M. Gibson, Maggie L. Kirkwood, Robert A. Lennie, James R. M'Curdie, Charles A. M'Guire, Guy D. M'Lean, John M. Macpherson, Thomas Martin, Kenneth D. Murchison, Andrew Peden, James F. Quigley (Lambhill), David W. Reid, John R. R. Ritchie, Alfred L. Robertson, Edwin Robertson, James H. Robertson, James I. Robertson, Frank Shearar, John F. M'G. Sloan, Alexander R. B. Soga, Graham Stevenson, Ronald Stewart, William P. A. Stewart, William Taylor, John C. T. Teggart, Janet M. Walker, George M. Whish, Frederick J. Whitelaw, Thomas Whitelaw, William F. Wood.

The following passed with distinction in the subjects indicated:—

In (a) Surgery and Clinical Surgery, (b) Practice of Medicine and Clinical Medicine.—James I. Robertson.

In (a) Surgery and Clinical Surgery, (b) Midwifery.—James H. Dible.

In (a) Practice of Medicine and Clinical Medicine, (b) Midwifery.—Thomas Martin.

In Surgery and Clinical Surgery.—Jane M. Davidson and Alexander R. B. Soga.

In Midwifery.—William B. Drummond, John M. Macpherson, David W. Reid, James H. Robertson, and William Taylor.

Royal College of Physicians of Ireland.

At the annual stated meeting of the President and Fellows of the Royal College of Physicians of Ireland, held on Friday, 18th inst., the following officers were elected for the coming year:—

President.—Dr. C. E. FitzGerald. Vice-President.—Dr. James Craig.

Censors.—Dr. James Craig, Dr. T. G. Moorhead, Dr. A. Nixon Montgomery, and Dr. T. Henry Wilson.

Examiners for the Licence to Practise Midwifery.—Dr. G. FitzGibbon and Dr. Holmes.

Additional Examiners to take the place of an Absent Censor or Examiner:—Medicine.—Dr. Parsons. Medical Jurisprudence and Hygiene.—Dr. H. T. Bewley. Midwifery. Dr. Hastings Tweedy.

Supplemental Examiners under the Conjoint Scheme:—Biology.—Dr. E. MacDowel Cosgrave. Chemistry. Dr. Lapper and Dr. N. Falkiner. Physics.—Dr. E. J. Watson and Dr. W. G. Harvey. Pharmacy, Materia Medica, and Therapeutics.—Dr. Travers Smith and Dr. D. J. O'Connor. Physiology.—Dr. H. C. Earl. Pathology.—Dr. F. C. Purser. (Medicine.—Dr. J. F. O'Carroll and Dr. H. C. Drury. Hygiene and Forensic Medicine.—Dr. W. A. Winter.

Examiners for the Conjoint Preliminary Examinations:—Languages.—Mr. E. H. Alton, F.T.C.D. Mathematics.—Mr. R. A. P. Rogers, F.T.C.D. Irish.—Mr. Edward de Valera, B.A., R.U.I.

Examiners for the Conjoint Diploma in Public Health:—Chemistry.—Dr. E. Lapper. Hygiene.—Dr. H. T. Bewley. Bacteriology.—Dr. H. C. Earl. Meteorology.—Dr. W. G. Harvey.

Examiners for the Membership of the College:—Practice of Medicine.—Dr. Martin Dempsey and Dr. T. G. Moorhead. Clinical Medicine.—Dr. J. Craig and Dr. George Peacocke. Pathology.—Dr. H. C. Earl and Dr. O'Sullivan. Obstetrics and Gynaecology.—Sir William J. Smyly and Dr. A. J. Horne. Representatives of the College on the Committee of Management.—Dr. Walter G. Smith, Sir John W. Moore, and Dr. T. P. C. Kirkpatrick. Representative of the College on the General Medical Council.—Sir John W. Moore. Treasurer.—Dr. H. T. Bewley. Registrar.—Dr. T. Percy C. Kirkpatrick. Librarian.—Mr. R. G. J. Phelps. Law Agents.—Messrs. S. Gordon and Sons. Agent to the Trust Estate.—Messrs. Townshends. Architect.—Mr. A. E. Murray, C.E.

Dr. Charles E. FitzGerald, the new President, practises as an ophthalmologist. He has been a Fellow of the College since 1886. He is Honorary Surgeon Oculist in Ordinary to the King in Ireland, Professor of Ophthalmic Surgery in the Royal College of

Surgeons, and Consulting Ophthalmic Surgeon to the Richmond Hospital.

The annual dinner was held last Saturday, 19th inst., being the morrow of St. Luke's Day, in the College Hall, the President in the chair. There was a large company of Fellows and guests. Among the speakers were:—The President, Dr. O'Carroll, the President of the Royal College of Surgeons (Dr. Purefoy), the Right Hon. the Attorney-General (Mr. O'Brien), the very Rev. the Dean of St. Patrick's (Dr. Ovendue), and the Registrar (Dr. Kirkpatrick).

The following is the prize list:—Winter Session, 1911-12:—Systematic Anatomy.—F. R. H. Mollan, first prize (£2) and medal; M. Moran and L. M. Rowlette (equal), second prize (£1) and certificate. Practical Anatomy.—First year—B. Hirson, first prize (£2) and medal; Miss E. Budd, second prize (£1) and certificate; second year—D. Kelly, first prize (£2) and Medal; J. O'Brien and D. V. O'Connor (equal), second prize (£1) and certificate. Practice of Medicine.—William I. Adams, first prize (£2) and medal; John D. Cherry, second prize (£1) and certificate. Surgery.—G. N. Smyth, first prize (£2) and medal; A. F. I. Patterson, second prize (£1) and certificate. Midwifery.—Geoffrey N. Smyth, first prize (£2) and medal; John D. Cherry, second prize (£1) and certificate. Pathology.—R. P. Weldon, first prize (£2) and medal; W. H. Carden, second prize (£1) and certificate. Physiology.—Edwin N. H. Gray, first prize (£2) and medal; A. P. Adams, second prize (£1) and certificate. Chemistry.—M. Mosbery, first prize (£2) and medal; Miss M. M'Mullen, second prize (£1) and certificate. Physics.—M. Mosbery, first prize (£2) and medal; Miss M. M'Mullen, second prize (£1) and certificate. Dental Anatomy.—J. J. Hutton, first prize.

Summer Session, 1912.—Carmichael Scholarship.—£15, G. M. C. Powell. Mayne Scholarship.—£8, M. J. Hillery. Gold Medal in Operative Surgery.—W. I. Adams. Silver Medal in Operative Surgery.—M. J. Hillery. Stoney Memorial Gold Medal in Anatomy.—G. M. C. Powell. Practical Histology.—N. E. Stephens, first prize (£2) and Medal; J. W. E. Graham, second prize (£1) and certificate. Practical Chemistry.—D. H. Ferris, first prize (£2) and medal; D. J. Steele, second prize (£1) and certificate. Public Health and Forensic Medicine.—G. M. C. Powell, first prize (£2) and medal; L. S. O'Grady, second prize (£1) and certificate. Materia Medica.—W. H. Carden, first prize (£2) and medal; G. M. C. Powell, second prize (£1) and certificate. Biology.—Miss E. Budd, first prize (£2) and medal; Miss M. M'Mullen and H. M. Alexander (equal), second prize (£1) and certificate. Surface and Topographical Anatomy.—J. C. Ferguson, first prize (£2) and medal; D. V. O'Connor, second prize (£1) and certificate.

University of Cambridge.

At a Congregation held on October 18th, the following degrees were conferred:—

M.D.—George Graham, Trin.; Alfred Bakewell Howitt, Clare.

M.C.—Frederic John Cleminson, Caius.

M.B., B.C.—Harold Bowring, King's; Alan Cecil Gemmell, Trin.

M.B.—Charles Barrow Wainwright, Caius; Llewellyn McIntyre Weeks, Caius.

B.C.—Charles Edward Redman, Pemb.; John Elliston, Down.

Conjoint Examinations in Ireland.

The following candidates have passed the examinations of the Royal College of Physicians and the Royal College of Surgeons, October, 1912:—

Preliminary Examination.—G. G. Allardyce, T. N. D'Arcy, W. Evans, L. Finnegan, W. Forde, G. E. Hare, P. J. Kelly, W. J. Marshall, H. L. Mooney, R. W. Morrison, T. P. MacDonnell, M. O'Connor, M. J. O'Reilly, E. S. W. Peatt, J. A. Power, G. C. F. Roe, J. C. Rutherford.

First Professional Examination.—J. H. Barrett, S. H. Berwitz, J. J. Campbell, B. J. Daunt, R. D'Alton, Miss E. M. Lloyd Dodd, C. K. T. Hewson, E. T. McElligot, T. Moore, P. O'Connell, J. Sharpe.

NOTICES TO CORRESPONDENTS, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS.

FOR ONE INSERTION.—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d. The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces. Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8 Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

F.R.C.S. (Hants).—The so-called catalytic action of metals in the colloid state is directly associated with the presence of the ultra-microscopic particles composing these substances, which appear to influence the biochemical processes of the living cells.

PNEUMONIA AND PUBLIC HEALTH.

ACCORDING to the last annual report of the Medical Officer of Health for the metropolitan borough of Islington, Dr. A. E. Harris, pneumonia is becoming of greater interest to public health authorities, though, up to the present, no definite attempts to schedule it among the notifiable diseases has been made in this country. Considering the importance of pneumonia and the fact that it is truly an infectious disease, it is interesting to note that a special weekly record of the deaths therefrom has been carefully kept since 1896 by Dr. Harris which has been specially charted for his report. It is most satisfactory to note that the death-rate of 14.9 per 1,000, though not the lowest on record, was nevertheless, with three exceptions, the lowest in a hundred years.

Dr. L. Y. (London, S.E.).—Conditions of localised œdema due to some lymphatic obstruction are not unknown as the more or less immediate result of traumatism, even though this be only slight.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, OCTOBER 23RD.

ROYAL SOCIETY OF MEDICINE (SECTION OF OPHTHALMOLOGY) (1 Wimpole Street, W.).—8.30 p.m.: Inaugural Business Meeting. Election of Officers.

HUNTERIAN SOCIETY, London Institution (Finsbury Circus, E.C.)—9 p.m.: The President (Mr. A. H. Tubby): Address. 9.15 p.m.: Discussion on Intravenous Anæsthesia.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.)—5.30 p.m.: Mr. J. F. Colyer: John Hunter's Specimens illustrating the Formation and Growth of Teeth. (Museum Demonstration.)

FRIDAY, OCTOBER 25TH.

ROYAL SOCIETY OF MEDICINE (SECTION FOR THE STUDY OF DISEASE IN CHILDREN) (1 Wimpole Street, W.).—4.30 p.m.: Cases by Dr. Porter Parkinson, Mr. Philip Turner, Mr. Sydney Stephenson, Dr. Reginald Miller, Mr. Maynard Heath, Mr. Duncan Fitzwilliams, Dr. F. J. Poynton, Mr. T. H. Kellock, Dr. Edmund Cantley. Specimens by Dr. Alexander Morrison. Papers: Dr. E. C. Williams: Notes on a Case of Precocious Development in a Boy, aged Six Years, with Photographs. Dr. Leonard Guthrie: Epidemic Catarrhal Jaundice.

ROYAL SOCIETY OF MEDICINE (SECTION OF BALNEOLOGY AND CLIMATOLOGY) (1 Wimpole Street, W.).—5.30 p.m.: Presidential Address: Dr. Percy Lewis: Sepsis and Spa Treatment. (The Annual Dinner of the Section will be held at the Cafe Royal, Regent Street, at 7.45 p.m.)

ROYAL SOCIETY OF MEDICINE (SECTION OF EPIDEMIOLOGY) (1 Wimpole Street, W.).—8.30 p.m.: Presidential Address: Dr. W. Hamer: The Influence of Migration upon the Phthisis Death Rate.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.)—5 p.m.: Prof. Keith: New Additions to the Collection of the College Museum.

MONDAY, OCTOBER 28TH.

MEDICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—8.30 p.m.: Communications relative to Hedonal Anæsthesia. (1) "A Further Communication as to its Uses in General Surgery," Mr. C. M. Page, M.S. (2) "Its Uses in Surgery, especially of the Nervous System," A. Z. Mennell. (3) "Its Uses in Children," Mr. L. E. Barrington Ward. (4) "Objection to the Use of Hedonal," Mr. J. F. Robson, M.S.

Appointments.

BOYD, SIDNEY, M.S.Lond., F.R.C.S.Eng., Surgeon to In-patients at the Belgrave Hospital for Children.
CROOKSHANK, F. G., M.D., M.R.C.P., Assistant Physician, the Belgrave Hospital for Children.
DONALD, ARCHIBALD, M.D. Edin., M.R.C.S., the Chair of Obstetrics and Gynecology in the Manchester University.
HENDERSON, WILLIAM T., M.B., B.Ch.R.U.I., Second Assistant Medical Officer at Hawkhead Asylum, Paisley.
HICKS, J. A. BRAXTON, M.D., B.S.Lond., D.P.H.Cantab., Pathologist and Registrar at Queen Charlotte's Lying-in Hospital.
HOWELL, B. WHITCHURCH, M.R.C.S., L.R.C.P.Lond., has been appointed House Physician to the Royal Free Hospital.
MACCORMAC, HENRY, M.B. Edin., M.R.C.P.Lond., Assistant Physician to the Department for Diseases of the Skin at the Middlesex Hospital.

Vacancies.

The Prudential Assurance Company.—Permanent Medical Officer at its principal office, Holborn Bars, London, Salary £500 per annum. Applications to General Manager.
Wakefield General Hospital.—Second House Surgeon. Salary £100 per annum, with board, lodgings, and washing. Applications to the Hon. Secretary, Clayton Hospital, Wakefield.
Bristol General Hospital.—Senior House Surgeon. Salary £120 per annum, with board, residence, etc. Applications to the Secretary.
Nottingham General Dispensary.—Assistant Resident Surgeon. Salary £170 per annum, with apartments, attendance, light, and fuel. Applications to C. Cheeseman, Secretary, 12, Low Pavement, Nottingham.
Stamford Hill and Stoke Newington Dispensary.—Assistant Resident Medical Officer. Salary £100 per annum, with board and apartments. Applications to the Honorary Secretary and Treasurer, Mr. G. H. Alexander, 83 Lordship Road, N.
Caterham Asylum.—Third Assistant Medical Officer. Salary £150 per annum, with board, lodging and washing. Applications to the Medical Superintendent, Caterham Asylum, Caterham, Surrey.
Wolverhampton Union.—Assistant Resident Medical Officer. Salary £150 per annum, together with furnished apartments, rations, etc. Applications to Frank Harrison, Clerk of the Guardians, Poor Law Offices, Wolverhampton.

Births.

FELL.—On Oct. 10th, at Flan How, Ulverston, the wife of Major M. H. G. Fell, R.A.M.C., of a daughter.
LITTLE.—On Oct. 20th, at 61 Wimpole Street, W., the wife of Dr. E. Graham Little, of a daughter.
MOYLES.—On Oct. 14th, to Dr. and Mrs. J. G. Moyles, 2 Bedford Road, Walton, Liverpool, a daughter.
STACK.—On Oct. 14th, at Arvalee, Clifton, the wife of Dr. Stack, of a son.
SYMES-THOMPSON.—On Oct. 21st, at 14 Gloucester Place, W., the wife of Henry E. Symes-Thompson, M.D., of a son.

Marriages.

GORMLEY-SKERRETT.—On Oct. 17th, at South Kensington, Lieutenant-Colonel J. A. Gormley, R.A.M.C., retired, to Rose Edith, daughter of the Rev. F. F. Kelly and widow of the late Major Skerrett.
MALLINS-PENRITH.—On Oct. 17th, at St. Luke's, Kensington, Clement Mallins, Lt.-Col., I.M.S. (retired), to Bessie, second daughter of the late Rev. T. H. Penrith.

Deaths.

BEARD.—On Oct. 13th, at St. Matthew's Vicarage, Oakley Square, N.W., Emily, wife of Charles Izard Beard, M.B., L.R.C.P., and daughter of the late William Izard, of Brighton, in her 85th year. R.I.P.
BURT.—On Oct. 12th, at Wolverton, from pneumonia, after a few days' illness, William Charles Burt, M.R.C.S., L.R.C.P., aged 53.
CHARLTON.—On Oct. 20th, at 1 Herbert Mansions, 35 Sloane Street, S.W., Fleet-Surgeon G. R. Deighton Charlton, Royal Navy, aged 62. R.I.P.
DUNCAN.—On Oct. 18th, at a nursing home, Andrew Duncan, M.D., B.S.Lond., F.R.C.P., F.R.C.S., Lieutenant-Colonel, late Indian Medical Service, eldest son of the late James Duncan, M.B.Lond., aged 62.
O'CONNOR.—On Oct. 20th, suddenly, at The Limes, March, Cambridgeshire, Charles Patrick O'Connor, M.D., M.R.C.S.

No. 18.

NOTES AND COMMENTS.

At the present moment the whole Insurance agitation centres around the B.M.A. and Sir James Barr. declaration coming from that source, therefore, is certain to attract immediate attention. The *Times* of Friday last, the 25th instant, publishes what purports to be an official statement of the policy of that body, which has every air of authority and is stated to come "from the office" of the Association. If that be the case it reveals a curious state of affairs in the inner life of that important body. It will be of interest to learn on whose responsibility in the "office" the authorisation was given to the *Times* for the publication of the following passage. "With reference to the banquet of the Irish medical profession," it runs, "Sir James Barr is attending as a guest. He will express his own opinion, no doubt, as he always does, but he will not be in an official position to make a statement on behalf of the Association, nor will Dr. Esmonde, M.P." Whatever the status of Sir James Barr as President of the British Medical Association, and the weight to be attached to his utterances at an important medical gathering on a medico-social subject of first-rate importance, apparently neither consideration overawed the gentleman in the "office" who took upon himself the responsibility of warning the public against attaching too much importance to what his chief was likely to say. It is much that same as if a clerk in the Treasury were to write to a London newspaper informing its readers that Mr. Lloyd George's views at a forthcoming meeting would not represent those of his department!

What is Loyalty? SURELY, the office of an Association should be loyal to its President. Or if the office be inspired by any strong feeling that in making a protest it is expressing the views of members generally, or of a representative governing body in particular, then its proper course of action is clear. Otherwise it is surely a confession of internal weakness if at the present crisis an administrative office girds openly at its President. The example is hardly inspiring at a moment when the need for absolute loyalty and subordination of personal feeling and opinion is above all things absolutely incumbent if the situation is to be saved. Sir James Barr, as everyone knows, is by nature impetuous, and at times oversteps the border line that would be observed by men of more restraint. On a former occasion when he lapsed into a personal attack on the Chancellor of the Exchequer, we felt it a duty to protest against his departure from the established ethics of public controversy. On an occasion like that of the Irish

Medical Graduates' gathering, however, it would be difficult to believe that he would deal with an extremely difficult and delicate position in any way likely to detract from the high position in which he has been placed by the medical profession. Meanwhile, the incident of the "office" warning suggests the desirability of the Association asserting itself more effectively in the management of its own affairs.

An Alderman on "Very High" Medical Fees.

It has long since been evident that the public, including the Chancellor of the Exchequer, have learned to appreciate medical services at an extraordinarily low value. Of all men a solicitor should know that the fee is given for advice that is the outcome of a vast outlay of time and money to acquire. Surely the member of a profession that charges (when it can) six and eightpence for writing or for reading a letter, and half that fee for answering a telephone call, would not be expected to cavil at payment for a night call, with all its attendant fatigues, or for a journey covering several or many miles distance. Yet the medical man is expected to perform responsible and arduous duties in return for a paltry fee. Could anything require more skill and technical knowledge than the proper handling of cases of consumption? In Preston the other day the Sanatorium Sub-Committee submitted a scale of charges to the Town Insurance Committee. For a report 5s. was allowed, and half-a-crown each for consultation at surgery; visit to patient; injection of vaccine (extra; drug to be supplied by authority); and consultation with tuberculosis officer (extra); night visits, 5s. Alderman Green objected to these charges on the ground that they were "very high." Probably he fails to realise the value of those services, or the high quality of the skill that is needed to perform them adequately. Local authorities find themselves obliged to turn to the medical profession for help, but they do not care to pay them adequately. It is a curious comment on the unworldliness of medical men that the same public which grudges their pence to a learned profession, nevertheless pours its money profusely into the coffers of the quack medicine man. It is all more or less a matter of education. The man in the street has been taught to pay high for advertised nostrums.

The Brompton Hospital for Consumption. IN the long history of the fight against tuberculosis, the Brompton Hospital for Consumption occupies a position of front rank. Long before the researches of Koch placed our knowledge of the malady upon a scientific basis,

pioneer work of an important kind had been carried on within the classic walls of that institution. The list of lecturers for the Michaelmas term comprises the names of a number of distinguished medical men. Amongst other instruction is that of a special post-graduate course in the diagnosis and treatment of pulmonary tuberculosis and the use of tuberculin. The staff have further issued a general invitation to all practitioners interested in the subject of tuberculosis to attend a gathering at the Hospital at 8.45 p.m. on Monday, November 4th. The new laboratories will be open to inspection upon that occasion, and Dr. Inman will give a demonstration on the varieties of the tubercle bacillus, illustrated by specimens kindly lent for the purpose by Dr. Stanley Griffith, the Scientific Investigator to the Royal Commission on Tuberculosis. It is hoped that those who purpose to attend this highly-interesting demonstration will intimate their intention beforehand to Dr. Cecil Wall, the Dean of the Hospital. Some of our readers may have heard the interesting rumour that the Brompton Hospital may be taken over by the Government and made the centre of a great national organised system of sanatoria and special institutions for fighting tuberculosis.

Pellagra and Insanity in the United Kingdom. DRs. LOUIS SAMBON and Chalmers have published in the *British Medical Journal* of October 24th a communication upon pellagra in the British Islands that must rank high in medical importance. The old

theory of the origin of this protean disease from the eating of diseased maize has for some time been abandoned. Sambon and Chambers have shown it to be due to a protozoan infection conveyed by a small midge, the *simulium*, which haunts the banks of rapidly-running streams. Before these discoveries the habitat of pellagra had been widely extended from its original endemic fields of Italy, Austria, the South of France and Spain. In 1907 it was found to be prevalent in America, and no less than 10,000 cases have been identified. The malady is characterised by recurring eruptions, by a chronic multiform affection extending over many years, and by nervous disturbances frequently ending in insanity. It is a disease, therefore, that may readily be overlooked on account of the very multiplicity and intangibility of its symptoms and the difficulty of bringing them within the limits of a correlated set of phenomena. Drs. Sambon and Chalmers have shown that many cases of pellagra exist in the United Kingdom, and that the *simulium* exists in many of its rapidly-flowing streams. They have therefore led the way for another advance into the territory of preventable disease. If their labours have the happy result of lessening the incidence of that most terrible of all endemic maladies, insanity, they will indeed have conferred a boon upon suffering humanity. Even to point out a probable preventable cause for mental disease in our midst is to furnish a great stimulus to medical research in a field where the outlook has hitherto been one of great obscurity.

LEADING ARTICLES.

THE INSURANCE ACT.

THE long-expected reply from Mr. Lloyd George has at length been given, and it remains for the medical profession to accept or reject his offer. Coming as it does at the end of October, that is

to say, two months before the medical benefits under the Insurance Act come into operation, the terms offered by the Chancellor of the Exchequer must be regarded as practically final. It therefore behoves medical men to consider the facts of the situation most carefully from all possible points of view before coming to a decision fraught with issues of vital consequence to their future welfare. That a considerable concession has been made by the Government is clear, inasmuch as it involves an additional expenditure of £1,650,000 per annum. There is a *suggestio falsi* about the matter, however, which seems to have misled the majority of the newspapers and of the public, namely, that the whole of this grant will go into the pockets of the medical profession. As a matter of fact, much of it is destined for other channels. The original offer was 6s. a year for each insured person, inclusive of drugs. This proposal was rejected by the medical profession, which demanded a minimum fee of 8s. 6d., exclusive of drugs and extras, an income limit, adequate medical representation on Insurance Committees, and free choice of doctors for insured persons. The Chancellor of the Exchequer has now offered sums which in their total amount reach a capitation grant of 8s. 6d. Of that amount it is proposed a minimum of 6s. 6d. be definitely assigned for medical remuneration and 1s. 6d. for drugs. A further sum of 6d. will be available for drugs when required, and will, under some circumstances, be alternatively available for medical fees. Another 6d. will be applicable from the sanatorium benefit fund for the payment of general practitioners attending tuberculosis cases. The outcome of the proposals, if we interpret Mr. Lloyd George's proposals correctly, is that medical men are offered a capitation fee of 7s., which, in some instances, will be increased to 7s. 6d., that amount to be exclusive of drugs. The first point to be settled is whether 7s. is to be accepted in view of the demand for 8s. 6d. The next point is the question of extras, including mileage, for which no allowance has been made. Is the Insurance doctor to do night work and go long distances without extra pay? Next consider the matter of the abuse of medical contract practice by the well-to-do member who can afford to pay fees for private attendance. No attempt has been made to remove that grievance, which rankles deeply in the minds of the medical profession. Why should not a limit be fixed for incomes beyond which the possessors should not be entitled to share in benefits deliberately devised by the State to help the poorer classes of society? What medical man who has been called to attend club patients living in luxuriously furnished private houses is ever likely to accept graciously, or with approval, any national scheme of insurance which does not provide against the repetition of that grave abuse? If Mr. Lloyd George has been compelled to submit to the views of the friendly societies upon this point, perhaps he will give medical men some inkling as to the motive of those organisations in insisting

upon the absence of a wage limit. It can hardly be supposed that the friendly societies wish to retain an empty and barren right which no one will exercise at the cost of the insurance doctor when he is once tethered securely to his post. Two further details that are likely to be criticised by medical men are, first, the proposal to control their attendance by a lay committee, and secondly, the demand for modern refinements of diagnosis, which are notoriously of a prohibitively costly nature. However, these and other points will be discussed forthwith completely by medical men in all parts of the Kingdom. There can be little doubt that a firm offer of 7s. 6d. is likely to attract a large number of practitioners. So far as the MEDICAL PRESS AND CIRCULAR is concerned, it seems clear that it would be unwise to attempt to assume any definite position at the present stage of negotiations. The report of the State Sickness Insurance Committee of the British Medical Association will be issued shortly, and will be considered by the Representative Council on November 19th and 20th. Whatever the decision of that body may be, it is to be hoped that the medical profession as a whole will uphold it to the last letter. It would be a serious blow to our newly-found faculty of collective organisation were the Representative Council to arrive at one decision and any considerable number of dissentients to act upon another. Now, if ever, is the time when the individual judgment should be loyally subordinated to that of the majority. It is naturally a temptation to men of strong character to differ from the voice of representative authority, but in the present case to dissent from the deliberate verdict of the representatives is to split a revolting force in the face of the enemy. Lastly, the proposal to impose the new conditions to a term of three years probation may influence the decision of many medical men. One important feature of Mr. Lloyd George's announcement was the intimation that failing a satisfactory agreement, steps would be taken to form a State Medical Service. How that is to be effected without the co-operation of the medical profession is somewhat of a mystery. In any case it would mean an indefinite addition to the outlay which has been made so grudgingly by the State for medical benefits. Within the next few weeks much history is likely to be written in the annals of the profession.

THE POSITION OF DENTISTRY.—III.

THE correspondence on the above subject, which was started in our pages in September last, has continued until to-day without losing in importance or interest. We are satisfied that it cannot at the least have failed to stimulate thought and activity in the direction of medical law reform; and when the preoccupations of the Insurance Act shall have ceased, with settlement of the burning questions there involved; when the Select Committee on Patent Medicines shall have issued its report and recommendations; when the profession seems once more free from further political activity, we shall do our best again to force the question to the front and keep it there. In our last article we discussed the General Medical Council and examined its defects as a representative body. It must be always borne in mind that the Council has very limited statutory powers, and has carried out its defined functions with respectable exactitude in the way of controlling education and registration. The Council has, however, not exercised with sufficient vigour the power that it has possessed of urging upon Government the need for amendment of

medical laws, the weaknesses of which have been thrust before it at every Session. If, for instance, the Medical Council had taken every opportunity of directing the attention of the Privy Council to the defects of the law, reform would by this time have been brought much further within the sphere of practical politics. The report issued by the Privy Council in 1910 on unqualified practice was the direct outcome of representations from the Medical Council. This suggests what more might have been done long ago by similar activity. The Council on discovering its statutory weaknesses might have asked for, might, indeed, with its authority, have virtually demanded, the necessary enlargement of its powers. It seems almost incredible that although elaborate laws have been devised to guard the public against gross forms of medical fraud, the Legislature has invariably omitted to make provision for the enforcement of these laws—has never appointed a public prosecutor or delegated the duty into the hands of any existing authority. The Medical Council can take cognizance only of offences committed by registered practitioners, and then only upon complaint from outside bodies; it has no power to initiate or carry on the prosecution of any unqualified pretender. The medical corporations—the Universities and the various colleges of physicians and surgeons—are merely educational and examining bodies, and have not the power, if they had the desire, to assume any other function. The vindication of medical law was left virtually to private enterprise, and years of delay in exposing its flaws were the result. That the construction of laws, for the effectual protection of the public and professions is a task not beyond the power of statesmen is evident. An attempt of an unqualified man to practise as a solicitor invariably meets with speedy condign punishment; and such a flagrant abuse as unchecked practice and assumption of titles by unqualified adventurers in the legal profession is virtually impossible. The working of the Veterinary Act affords, again, an exemplification very much to the point. This Act became law in August, 1881. It is modelled on the lines of the Dentists Act; but the functions exercised by the Medical Council under the latter are delegated to the Royal College of Veterinary Surgeons, with the added duty of enforcing the Act. The preamble of the Act states that its main purpose is to make provision "to enable persons requiring the aid of a veterinary surgeon for the cure or prevention of diseases in, or injuries to, horses and other animals to distinguish between qualified and unqualified practitioners." The penal clauses of the Act directed to this purpose differ little in their wording from, and are precisely the same in sense as those of, the Dentists Act. The College of Veterinary Surgeons encountered no difficulty in vindicating the law. It had long been the custom for unqualified farriers to display a sign inscribed "Veterinary Forge." A number of these men were summoned under the Act on the ground that the use of the word "veterinary" was calculated to lead to their being mistaken for qualified veterinary surgeons; and although it was pleaded that they had acted without intent to deceive, they were in every instance heavily fined. No attempt being made to reverse in the High Court these magisterial decisions, the Veterinary Act was thus fully vindicated. There is nothing to hinder unqualified men from practising veterinary surgery, so long as they do not pretend to be legally qualified; the public are protected so far as possible from mistaking unqualified pretenders for properly educated practitioners; and

poor dumb brutes are also, thus far safeguarded against the torments which unscientific "veterinary surgery" so often inflicts upon its victims. The Medical Acts devised to provide for men the same protection as the Veterinary Act affords to brutes, date from 1858; and the Dentists Act from 1878. Under none of these Acts through all these years has it been possible to check the evils they were devised to prevent; they remain dead letters. The case for drastic reform of medical law is overwhelming; to work for this reform is a pressing duty which the profession owes to itself and to humanity.

CURRENT TOPICS.

The King and Tropical Medicine.

THE friends and supporters of the London School of Tropical Medicine will note with pleasure that his Majesty the King has been graciously pleased to mark his interest in the school and his care for the welfare of his tropical Dominions by sending a contribution of £100 to the fund recently opened by the Lord Mayor in response to an appeal by Mr. Austen Chamberlain, who has received the following letter signed by Sir William Carrington:—"The King commands me to enclose a cheque for £100 towards the London School of Tropical Medicine, which his Majesty trusts will continue to extend its excellent work. The King notes with interest that the school owes its inception to your father." In forwarding this letter for publication, Mr. Austen Chamberlain writes:—"His Majesty's interest and approval encourage us to make a renewed effort to secure the £100,000 for which we originally asked. We have already secured nearly half that sum. But more is urgently needed to place the school on a sound financial basis, and to enable it to prosecute effectively the great work of training and research by which the deadliest terrors of tropical life are being steadily eliminated, the death-roll of whites and natives alike is being diminished, and the development of these fertile lands is rendered possible without the terrible suffering and loss of life which it has previously entailed." Donations may be sent to the Secretary of the London School of Tropical Medicine, Seamen's Hospital, Greenwich, or to Mr. Chamberlain, either of whom will be glad to supply correspondents with any further information they desire.

Notification of Consumption in France.

SOME time ago we gave the comparative statistics of pulmonary tuberculosis in Berlin, London and Paris, and showed how badly "La Ville Lumière" came out of the inquiry. There can be no doubt that the prime cause of the spread of phthisis in Paris lies in the bad housing of the poorer classes. Although the families practically never number more than three children, these, with their parents, are lodged, as a rule, in one or two small, unventilated rooms into which enough sunlight never penetrates, whilst the tenements throughout are too often filthy and permeated by foul air drawn in from sewer or cesspool *via* untrapped and unventilated soil pipes. It is evident that much more good would be done by attacking root causes like these than by measures of isolation and attempted cure of victims of disease. This view was very strongly urged at a meeting of the Academy of Medicine last week, when the subject was brought up—in a discussion on the proposed compulsory notification of consumption—Professor Robin, who led the attack on this proposal, was supported almost unanimously by the meeting.

He said that such a scheme was impossible in any country where it was disliked by the people, and in France it would provoke a revolt—French doctors would, he alleged, never take up the policeman's work of handing over to the sanitary authorities patients who had confided in them. He then went on to examine the question of expense. This Dr. Robin believed would not be less than forty millions. It would be necessary to support vast numbers who would be taken from employment and pauperised. He urged that the money would be much better spent in ameliorating conditions of life among the poor, in improving their health, especially by better housing, so that the tuberculosis bacilli which everyone swallows by the myriad daily would find no soil for their culture.

"Vis Mafactrix Naturae."

THE healing power of "Nature's own sweet and cunning hand" has been sung so often by the poets and bedside clinicians that we have almost come to regard it as perfect. We commend a system of treatment as "natural," and what higher praise can we give a remedy than that it is "Nature's own"? If we look, however, at Nature's work with the modern eye of criticism we find her sometimes a poor enough bungler in therapeutics. She has three or four ways of dealing with all emergencies, and these are not always efficient. Fever, force, swelling and scar-tissue make up much of her armament, and we find her "exerting an unweary power" with one or other of these in season and out of season. If our body lodges a few pneumococci Nature runs up our temperature in a very ineffective effort to kill the invaders. She pushes a stone along a tube never intended for such traffic, till its unfortunate owner collapses from the pain. Any local trouble is promptly dealt with by a swelling. Often this is comparatively harmless; but why obliterate an unfortunate child's glottis to attract attention to some slight laryngeal irritation? And then her methods of repair; "one touch of Nature makes the whole world" scar-tissue, a substance that contracts when it should stretch, and stretches when it should contract, till our hospitals are "rich with the spoils of Nature." The trouble is that Nature has no second string. She has one way of dealing with a given condition, and if that fails—she keeps on doing it. Her methods are fairly satisfactory as a temporary treatment, but they do not bear the test of time—scar-tissue will fill a gap, but after a few weeks its failings become very obvious. If she would learn to apply a little more discrimination to the use of her remedies, she might even now live down the reproach we are sorry to say she has earned, of being somewhat of a short-sighted empiricist in many of her therapeutic efforts.

The Quality of Milk in Relation with the Food of Cows.

THE report recently published by the Edinburgh College of Agriculture gives the results of experiments to show the effect of heavy root feeding on the quantity and composition of milk. The belief was long entertained that the quality, as well as the quantity, of milk given by a cow could be influenced by altering the diet, but the new theory that there is only an indirect, if any, connection between the ration and the amount of fat and other solids in milk is now commonly accepted. The Edinburgh experiments confirm this interpretation, and their teaching may be commended to the notice not only of public officials concerned with the administration of the law as it affects the milk supply, but of scientific investigators in similar fields. If any diet would tend to increase the yield of

milk and lower the percentage of fat, a heavy allowance of roots containing about 90 per cent. of water might be expected to have such a result. The special ration in the recorded experiments included 112 lbs. of turnips, compared with 40 lbs. in the ordinary ration, the same quantities of hay and straw being given in both cases, while along with the larger quantity of roots the cows received 4 lbs. each per day of concentrated stuffs, as against 10 lbs. each given to the other lot. The results are conclusive, being based upon trials repeated in three successive winters. The cows that received the turnip ration gave richer milk, though less of it, than those fed with the concentrated ration. This proves that, whereas the quantity of milk is affected directly by the food consumed, the percentage of fat and other solids depends upon the inherent merits of the cow herself. The fact that the concentrated ration resulted in a milk yield with a lower percentage of fat does not mean that watery food is productive of fat, but implies rather rich feeding increases quantity disproportionately to quality.

The "Edinburgh Review" on Secret Remedies.

It is hard to understand how an article of the quality of that on "Secret Remedies," in the current issue should find admission to the *Edinburgh Review*. The writer shows himself lacking in knowledge of fundamental facts without which it is impossible to understand the question, much less to pass judgment upon it. It would be tedious to go through all his errors. He does not seem to be aware of the difference between legitimate pharmaceutical preparations, the constituents of which are fully revealed, and nostrums put forth with the pretence that they contain potent agents unknown to medical men. The writer does not seem to understand that there exists in fact no such thing as a "secret" remedy; that chemical analysis easily discloses the constituents, and has been applied to the great majority of nostrums. He does not seem aware of the notorious fact that although "secret" remedies are sometimes made up of opiates or of alcohol, or cocaine, as in many of the sham tonics extensively advertised, they rarely contain anything more potent than a small dose of cheap purgative. It is amazing to see a writer assuming an air of authority on this question who does not appear to know that chemistry is one of the most advanced of the sciences, and that it needs only a small amount of practical skill in it to separate and determine the quantities of the ingredients in any ordinary inorganic or organic compound, whilst an accomplished analyst finds little difficulty even in tracing and recovering a minute quantity of the most elusive of alkaloids deposited within the tissues of a body dead from poisoning. He does not, apparently, see that if quack medicines contained unknown agents they would be discoverable and separable. The vast majority are worthless trash, and the harm they do arises from reliance being placed upon them in serious diseases. In every department of every hospital there are always to be discovered numbers of patients with simple diseases which have become chronic, and serious maladies which have passed into a mortal phase owing to delay in applying scientific treatment. All these facts are ignored by this presumptuous and ill-informed writer.

PERSONAL.

MR. V. ZACHARY COPE, M.D., M.S.Lond., F.R.C.S., has been appointed Surgeon to the Bolingbroke Hospital, Wandsworth.

H.M. THE KING has been pleased to confer the decoration of Member of the Victorian Order (fourth class) upon Dr. Edgar Hoffmeister, of East Cowes, surgeon to the Royal Family at Osborne.

DR. F. G. CROOKSHANK, M.D., M.R.C.P., has been appointed Assistant-physician to the Belgrave Hospital for Children.

CAPTAIN P. DWYER, R.A.M.C., has been selected for appointment as Specialist in Otology at the Royal Infirmary, Phoenix Park, Dublin.

CAPTAIN P. A. LLOYD-JONES, R.A.M.C., has been selected for appointment as Specialist in Ophthalmology at the Cambridge Hospital, Aldershot.

MR. CHAD WOODWARD, M.B., Ch.B.Edin., F.R.C.S., has been appointed Surgeon to Out-Patients at the Hampstead General and North-West London Hospital.

MR. BRYDEN GLENDINING, M.B., M.S.Durh., F.R.C.S., has been appointed Gynaecologist to the Hampstead General and North-West London Hospital.

DR. FREDERICK TAYLOR, M.D., F.R.C.P., has been elected Chairman of the Committee of Medical Members of the Senate of the University of London for the ensuing year.

DR. HENRY GIFFORD CRIBB, of the London County Asylum, has been appointed superintendent of the Durham County Asylum at Sedgfield, in succession to Dr. Skene, retired.

THE Council of Bedford College for Women, London University, have recently received from Miss May Tweedy a gift of £500 towards the fittings of the Physiological Laboratory.

MR. HENRY C. BAZETT, M.B.Oxon., F.R.C.S., of Wadham College, Oxford, and Radcliffe Travelling Fellow, has been elected to a Fellowship in Medical Science at Magdalen College.

THE Lord Lieutenant of Ireland has appointed Sir Thomas Myles, M.D., to be a Governor of the House of Industry Hospitals in the room of Sir William Thornley Stoker, deceased.

MR. CHARLES ALFRED BALLANCE, M.V.O., M.S., F.R.C.S., of St. Thomas's Hospital, has been appointed by the Home Secretary to be Chief Surgeon of the Metropolitan Police, in place of the late Mr. Clinton Dent.

DR. T. P. COWEN, Senior Assistant Medical Officer at Prestwich Asylum, has been appointed by the Lancashire Asylums Board to be Medical Superintendent of Rainhill Asylum, in succession to Dr. Wigglesworth, resigned.

MR. E. C. TEMPLE-SMITH, D.O.Oxon., M.B., Ch.B., R.U.I., F.R.C.S.E., has been appointed Honorary Ophthalmic Surgeon to the Liverpool State Hospital and Asylum for the Infirm, Sydney, New South Wales.

THE Lady Mayoress of London has kindly promised to take the chair at the annual meeting of the Royal Medical Benevolent Fund on Friday next at the Mansion House. Tea will be provided at 4.30 p.m., followed by the meeting at 5 o'clock.

SIR ALMROTH WRIGHT, F.R.S., will deliver the opening address of the winter session of the North-East London Post-Graduate College, Prince of Wales's General Hospital, Tottenham, N., this afternoon, Wednesday, at 4.30 p.m., on "Lymph Drainage as a Therapeutic Measure."

SIR WILLIAM JAPP SINCLAIR, M.D., for some years joint editor of the *Medical Chronicle*, and one of the founders of the *Journal of Obstetrics*, Professor of Obstetrics and Gynaecology at Victoria University, Manchester, who died on August 21, aged 66, left estate of the gross value of £856.

A CLINICAL LECTURE

ON

THE TREATMENT OF ICTERUS.

By G. HOPPE-SEYLER, M.D.,

Professor of Medicine in the University of Kiel.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

GENTLEMEN,—In jaundice there is usually an overflow of the bile constituents, especially bilirubin, into the blood current and connective tissues, caused by some hindrance to the flow of bile from the liver, often complete blocking up of the bile passages, and consequent stasis of the bile in the bile ducts. The simplest case is that blocking up of the bile in the choledochus by gall stones, parasites, or tumour. In infection of the bile ducts also they get blocked through inflammatory swelling of the mucous membrane and the submucosa, especially the lower part of the choledochus. In intoxications also, retention of bile may play a part, as in lead-poisoning, from increased formation of biliary colouring matter, from destruction of the colouring matter of blood and consequent increased tenacity of the bile from excess of bilirubin (Pleiochromia, Icterus polycholicus) as then the bile flows too slowly, and in consequence over-filling of the smaller bile passages takes place. In infections and intoxications of the bile passages and the liver and for the passing over of the constituents of bile, injury to the liver cells also plays a part, which renders possible the passage of the bile into the blood or lymph capillaries. (Diffusion icterus, acathectic icterus, parapadesis of the bile.)

In intoxications with powerful protoplasm poisons (phosphorus, etc.) as well as in the severest inflammations of the parenchyma of the liver, wherein a rapid fermentative destruction of the parenchyma takes place, this injury occupies a prominent position. In long-standing congestive jaundice also through the injurious action of the bile constituents disturbance of the liver cells takes place, especially when very powerful micro-organisms are present in the bile passages; this may go as far as acute atrophy. Here this damage to the cells may follow very rapidly. In simple bile stasis by blocking of the choledochus it may be comparatively late, even months after. But after every attack of jaundice we must take into account that the parenchyma of the liver has been more or less injured; this must be kept in mind and a plan of treatment must be instituted later on.

The most frequent form of icterus, jaundice, in common parlance, is catarrhal icterus. According to recent views it is caused by infection of the bile passages from the duodenum (especially coli bacilli). According to experimental investigations the excitors of the disease may pass from the blood into the bile passages, as with typhoid, paratyphoid bacilli. The connection with infectious stomach and intestinal diseases is of great importance, both from a prophylactic and therapeutical point of view.

For the treatment of icterus, therefore, the following points come into consideration:—

1. Removal of all infection and intoxications from the gastro-intestinal canal and the bile passages.
2. Overcome the stagnation of the bile current.
3. Protection of the parenchyma of the liver, so that this itself does not become diseased, by keeping away from it everything that would weaken it.
4. Attention to the absence of bile in the intestinal

contents and to the different course of the decompositions that are the result of it. If the infection and its action on the bile passages is limited or has ceased the swelling of the mucous passages and the biliary congestion will become less or cease altogether. At the same time the parenchyma of the liver will be the more rapidly freed from the effects of the biliary stasis and the infection. If the absence of bile from the intestines is not sufficiently attended to greater decompositions of food material and the development of abnormal products of tissue change may follow, which will act deleteriously upon the liver by absorption from the intestines into the portal vein. And so attention to one point will have a favourable effect on the other disturbances.

The treatment in the most frequent form of jaundice—catarrhal icterus—will commence with removal of infectious and toxic material from the gastro-intestinal canal. For this it is best to order calomel (5 to 7 grains) the dose to be repeated if the result is not sufficiently active—if it does not procure a sufficient action of the bowels. If no action whatever follows, castor oil, rhubarb or senna must be given and assisted by enemata of water. Fever is frequently seen to subside after this. At the same time the heightened peristaltic action of the bowels also stimulates the muscles of the bile passages, so that evacuation of stagnated bile is possible when the swelling of the mucous surfaces of the bile passages is only slight. The bowels must now be kept open regularly, as otherwise the excitors of infection gain a stronger development and abnormal decompositions of the intestinal contents with fermentation and the development of foul products will take place. The purgative salts of the sulphate group—sodium and magnesium sulphate—are the chief means for this. Or the following:

Sodii Sulph. 20.

Infus. Rhub. 5 to 180.

One tablespoonful several times a day appears suitable.

In order to lessen the catarrhal irritation in the bowel and so get rid of the excessive quantity of mucus, bicarbonate of soda may be added. Carlsbad water answers excellently, the chief constituents of which are chloride of sodium, bicarbonate of sodium, and sodium sulphate. Its carbonic acid content at the same time excites peristalsis and makes it more palatable and more readily borne. Of this two glasses should be taken warm fasting in the morning; if there is constipation it should be taken cold a quarter of an hour before breakfast, or one or two glasses after dinner before the coffee. In better-class practice the natural water may be given, otherwise, a teaspoonful of Carlsbad salts may be given in half a glass of hot water with an equal part of Seltzer water. If there is diarrhoea to begin with calomel is still to be given first of all, then an astringent such as tannalbin, tannigen, bismuth subnitrate, 1 gm. several times a day, when the diarrhoea is persistent.

The Carlsbad water drunk hot appears to have a favourable effect on the diarrhoea. Cholagogues are then to be advised in order to satisfy the indication to remove the collected bile. The oleic salts sodium oleate, eunatrol, biliary acid combinations (Ovagal) are suitable for this. An excessive production of bile here is not indicated as this would only make the injurious effect of that which has accumulated worse. If eunatrol, cholelysin and similar medicines act favourably, it is only on account of their purgative action. Podophyllin, which is so much thought of, can only act in this way as it has no effect on the secretion of bile itself. The cholagogue tablets, which contain calomel podophyllin, act in the same way. In a similar way the secretion of bile is not increased by giving large quantities of water, but it is still indicated for washing out the system. The water enemata recommended on these grounds of 2 litres of water and given several times a day (Mosler, Krull) especially when they are given cold, independent of their evacuating action, only have the effect of exciting the peristaltic action of the bowels and bile passages. With the large mass of remains of food, which have been retained, or but slowly evacuated through exclusion of the bile from the intestinal tract they are therefore very suitable. If the evacuations are very hard oil enemata up to $\frac{1}{2}$ or $\frac{1}{3}$ litre are made use of.

So long as there is any fever Preissnitz applications are useful, also later hot ones such as meal poultices, thermophores, etc., over the region of the liver.

On the other hand, the usual physical remedies, massage, electrification of the liver and gall-bladder promise but little; they may even have an injurious effect from irritation of the liver and bile ducts.

So long as the jaundice persists, rest is of great importance as regards the liver. Especially when fever is present absolute rest in bed is necessary, and it is well to continue it so long as bile pigment appears in the urine; the bile passes freely into the intestines and the motions are intensively coloured with it. Otherwise there is the danger—although it is by no means a frequent occurrence—that serious symptoms of degeneration of the liver and autolysis, acute atrophy of the liver may show themselves, although they are not of frequent occurrence.

The diet must be suited to the changed condition, to the infection, the biliary stasis, and the changed conditions of digestion consequent on the absence of bile in the alimentary canal. It should not contain any strong spices or alcohol which excite the liver and bowels, the food should not readily undergo decomposition, must contain but little indigestible material and but little fat, as this when the bile is shut off is not readily absorbed and so leads to decomposition. It is true that the faculty of splitting up fat is retained, but resorption is difficult, perhaps from absence of the bile acids. At the same time milk, in spite of its fatty constituents, is always well borne, especially in the form of milk gruel, or prepared with sago, rice, groats, or cornflour. Oatmeal gruel, Quaker oats, best also prepared with milk, barley water, pearl barley, etc., are also suitable. Biscuits may be given at the commencement, later a little toast with a very little butter.

The digestion for meat should not be very much disturbed, but it often is. Possibly a simultaneous disturbance of the vessels of the pancreas may account for this. There may be also gastric disturbances at the same time whereby the power of digesting meat, especially in its raw state, may be upset. In icterus many considerable disturbances

take place in the intestines, which lead to toxic decompositions, which again lead to further disturbance of the liver. In any case, jaundiced people often show a repugnance to meat. In many cases of jaundice, too, there is an excessive production of acid in the stomach, whereby the above-named disturbances appear more rarely. In place of meat eggs might be given, and in place of fats, starchy foods or biscuits, rice, etc. It must be borne in mind, however, that the fermentation in the intestines will be greater with this diet, and that the meteorism set up will be distressful to the patient. For this reason it will be well to vary the diet as much as possible before the disturbances become of any account, and change to an egg diet for a time. A free supply of liquids is proper in the shape of milk, buttermilk, alkaline mineral waters, fruit juice, tea, etc., whilst alcoholics must be avoided.

When bile is again emptied into the bowel fat may again be given and the ordinary diet gradually resumed. But one should still be careful to avoid readily decomposable foods, such as many kinds of meat, cheese, fish, sausages, in order not to set up a catarrh of the intestines, and through that a relapse on the part of the liver.

During the whole time the jaundice is at its height, therefore, something like the following diet should be prescribed:—Breakfast: Milk with tea or cocoa, biscuit or rolls, or a lightly-boiled egg. Early lunch: Milk or soup, clear or thick, with an egg. Lunch: Milk soup with rice, semolina, sago, bouillon, thick soup, lean meat, mashed potatoes, macaroni, easily digested vegetables, such as spinach, cauliflower, carrots, etc., light (not fatty) milk puddings. Afternoon: A little milk with biscuit (rusk). Evening: Milk soup, thick soup, or tea with milk, white bread, a little butter, lean meat and egg. During the first febrile stage it is best to give nothing but milk soups, oatmeal gruel, bouillon, and a little biscuit.

During convalescence one may give at midday a little more meat (beef or game), light vegetables but not cooked with fat, some cooked fruit. If the case is one in which the infection is more severe, with purulent inflammation of the bile passages (cholangitis suppurativa), it is best to give some preparation of salicin: Sodium salicylate, aspirin, salol $1\frac{1}{2}$ to 3 gm. pro die so as to act on the excitors of the inflammation by the passing of salicylates over the tracts. Menthol, which has a similar action and passes into the bile, can hardly be given without irritation of the stomach and bowels. A copious supply of liquids, especially in the form of the alkaline mineral waters, is useful in order to remove the toxic material from the system as quickly as possible. If this line of treatment, however, does not answer the purpose quickly and carry off the infected bile, it must be done by drainage of the hepaticus as recommended by Kehr, the formation of a biliary fistula, which can be made by passing the thermocautery into the liver.

Icterus infectiosus or gravis (Weil's disease), besides the dietetic treatment required for catarrhal jaundice, demands special attention to the greater infection which is associated with high fever. This, like typhoid fever, requires cold water treatment, cool baths, packings, cold water pillows, or antipyretics such as quinine, salicyl preparations, etc. Epidemic jaundice mostly resembles the catarrhal form, demands the treatment of that form; when it resembles the grave form the treatment of that form must be given.

In the matter of essentials the jaundice must be treated in the same way when it occurs in the course of other infective diseases, such as typhoid,

recurrent fever, pneumonia, septic pyæmia, regard being always had to the main or original disorder.

Icterus in syphilis may be the expression of a chronic cholangitis and pericholangitis with extension of the inflammation and growth of connective tissue on the acini of the liver or pressure of enlarged portal glands on the hepatic duct. Besides potassic iodide and mercury, and if need be, salvarsan, a careful mode of life and a suitable diet must be aimed at, in order to protect the liver, weakened by the disease, from injury and prevent the onset of acute atrophy. Many cases of hypertrophic cirrhosis of the liver may be traced to syphilis, and are to be treated correspondingly. The fever subsides in cases of this kind with the greatest certainty with large doses of potassic iodide. Icterus in new-born children, when it runs a bad course and frequently or regularly comes on in children of the same parents, gives rise to a suspicion of syphilis, and should therefore be treated specifically.

The forms of icterus in consequence of excitement or mental disturbance or menstruation, appear as the chronic icterus that runs in families; it usually requires no special treatment beyond great care and a regulated mode of living.

In the case of various poisons: Arsenic, phosphorus, fungus poisoning (helvellic acid from helvella, phallin from agaricus phalloides), hydrazin phenylhydrazin, aniline and its derivatives, quinine, tuberculine, etc., there may be jaundice, in which the poison is to be got rid of as speedily as practicable or care taken to prevent further ingestion of it, so that the diet should be as mild as possible.

In conclusion, it should be mentioned once more that the appearance of jaundice, even with absence of any general disturbance, is always a warning to be cautious; it demands that its cause should be discovered, and that the patient be kept under observation, whilst a corresponding suitable diet and mode of life should be prescribed. For diseases of the bile passages that may appear of little importance may lead to serious disease of the liver (acute atrophy), which, considering the importance of the organ in the economy of the body, may be very dangerous.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by W. Langdon Brown, M.D., F.R.C.P., Physician to the Metropolitan Hospital and Medical Registrar to St. Bartholomew's Hospital. Subject: "Jaundice."

ORIGINAL PAPERS.

CONCERNING DIET IN NERVOUS DISORDERS.

By TOM A. WILLIAMS, M.B., C.M. EDIN.,
Washington, D.C.

Foreign Corresponding Member, Paris Neurological Society, &c.
GENERAL CONSIDERATIONS.

THE astonishing neglect of the scientific method in the therapeutics of nervous disease is nowhere more striking than where diet is concerned. Grasset's work, bristling with references, devotes hardly a page, and that in only the most general way, to the subject of alimentation. Oppenheim's scattered remarks about diet are traditional, merely indicating that he has given no real thought to the significance of the subject. Of works in English the unsatisfactory nature must be known to all. It is true that a few scattered articles, more especially in the French literature, have drawn attention to the importance of a diet mainly of milk and vegetable products in persons

supposedly predisposed to nervousness, by a constitution which the French call arthritic, and former English writers lithemic. But since the work of Weir Mitchell, I know of no important presentation discussing the rôle of diet in the management of the sufferers from affections of the nervous system. Moreover, the conclusions of *Fat and Blood* were largely empirical and cannot be entirely endorsed in the light of our better recent knowledge. The irrationality of forced feeding, even in tuberculosis, is established, and the practice has lost favour. The idea of nerve starvation has been found to be only partially correct; for the defective activities of the nerve elements are now generally attributed, not to deficient aliment, but to excess of waste products or other deleterious substances. That is to say, intoxication has become a dominant interpretation.

I am not prepared to say how far the not infrequent success of the Weir Mitchell method can be accounted for on this principle, for the method is one with many factors and was applied to a variety of cases differing in pathogenesis. But many of the failures of the method may perhaps be accounted for by the presence of a toxicosis which none of the numerous procedures reached, or which was, perhaps, even exaggerated by the abundant diet ingested. We are well aware that in depleted conditions, even when these are toxicogenic, large amounts of nourishment can be assimilated. Convalescence from wasting diseases is a familiar illustration.

Studies in metabolism have shown us how badly balanced is the diet of the average prosperous city dweller of our day. Excess of proteids and deficiency of carbohydrates, and sometimes of salines, is the rule. When the defences fail, conversion of the proteins into the proper aminoacids is incomplete, and the substances produced may act as nerve poisons. In these cases the caloric needs of the body may find better fulfilment in an abundant diet of carbohydrates within the limits of hepatic tolerance. An addition to the fats may also be beneficial within limits. Of the latter, those selected should be of low melting point; otherwise, in neurotic patients, intestinal sand—a misnomer, for in reality the grains are soap—may form, and a mucous colitis appears. This connotes a waste of the intestinal secretions used in saponification. The best fats are olive oil and butter fat; but the carbohydrates should be the mainstay as a rule.

Unfortunately, too, many of the modern consumer's carbohydrates are supplied in a form which emasculates from them substances of great advantage. It is a pity that experimental proof of this opinion has been lacking until recently, so that due weight was not given it by most physicians. Even the extensive clinical and laboratory investigation conducted in England recently to establish the relative merits of bread made from commercial flour and that from whole wheat, permitted of no definite conclusion, for attention was too largely confined to the caloric value of the result in bread. But that there is a substance of great importance for nutrition in that part of the cereal which is usually rejected in commercial preparation is now experimentally proved by the production of the nerve degeneration in animals fed solely upon polished rice.

Almost in the nature of an experiment is the abolition of beriberi in the compounds where coolies receive unpolished rice instead of the polished product, under the consumption of which beriberi prevailed. The former supposition that the disease arose from a fungus in the rice seems to have been disposed of by the experiments. Moreover, the substance which prevents the beriberi, if we may accept the nerve degeneration in animals as of the same nature, is inseparable from the rice polish by solution in alcohol and water, although its nature is not yet ascertained.

Further evidence that whole cereals contain a nutritive substance of importance for the internal secretions is furnished by Chalmers Watson's researches into the growth of the thyroid gland under different diets. He showed that on an exclusively flesh diet, thyroid gland of young rats underwent hypoplasia, whereas when oatmeal was the exclusive diet, the gland developed freely. The latter animals greatly

exceeded in growth and capacity those fed only on flesh.

Although I do not know of experimental verification, it is legitimate to infer from the foregoing facts (as we know that an animal fed on carbohydrates alone emaciates and dies quickly) that a substance of great value to the nervous system in particular is removed in the milling of grains, and that this cannot be replaced adequately by the addition of flesh. Whether this substance exerts its action as a direct nutrient, or through the medium of the hemopoietic or other glands of internal secretion, we do not know; but to the therapist, this is of less interest than the conclusion itself. For in the regulation of the activity of the nervous system, the secretion of the thyroid gland is an essential. Many cases formerly designated neurasthenia and hysteria are now known to be merely due to changes in thyroid secretion.

Were one to speculate, it might be supposed that the prevalence in our day of hyperthyroidism expressed the response of this gland to a vascular environment which insufficiently supplies it with pabulum for the work the body requires of it, and that it responds by a secretion which makes up in abundance for what it lacks in quality, and thus inaugurates a vicious circle which maintains itself.

One cannot here enter into the qualifying factors of this hypothesis, those, for example, furnished by fear and anxiety in stimulating the thyroid secretion.

Other important substances in the portion commercially removed from grain are calcium and the phosphates. Although these are present also in flesh, yet to obtain them in adequate amount from this alone would entail a greatly excessive ingestion of proteid. The thoughtless appeal to the carnivora as an example of ebullism forgets that these animals eat the bones as well as the flesh. Now the bran is the bone of the wheat, hence many modern diets lack enough of phosphates and of calcium.

Now, experiments have shown that calcium is one of the stabilisers of nerve activity, while potassium and sodium are its excitants. Phosphates are known to be a necessary pabulum of nerve. Is it not evident, then, that what clinicians call weak irritability must ensue when stabiliser and pabulum are deficient?

Deprivation of any necessary aliment leads to craving. The conscious expression of this may not be directed towards that which is lacking. It often expresses itself morbidly, such as in desire for alcohol, or in the peculiar longings of the gravid woman. It may manifest itself psychologically, as in the feeling of incompleteness of the psychasthenic.

PSYCHIC SURROUNDINGS MUST BE FAVOURABLE.

This leads us to a most important matter in dieting against nervous disorders. As it is not ingestion, but assimilation, at which we must aim, all the factors which make for this must be employed. Most important among these is enjoyment of the food. It must be cooked and served appetisingly. But even this is not enough: the psychological surroundings must be favourable. Dejection or anxiety are most detrimental to proper digestion. To corroborate this clinical opinion, we now have the experimental data of Pawlow. But we must avoid the other extreme of an excessive gaiety or cheerfulness during the meals of neurotic or excitable persons, for the mental activity thus stimulated is not the most favourable state for good anabolism.

PREPAREDNESS FOR FOOD; EXERCISE; INTERVALS BETWEEN MEALS.

The highest degree of preparedness for proper assimilation occurs only when the digestive glands are free from the incubus of a preceding meal. A loaded liver and an exhausted pancreas are not favourable. The rapid circulation and oxidation produced by active exercise are the best preparation for the proper assimilation of food. It should be evident that the frequent ingestion of food is detrimental to those persons susceptible to alimentary poisoning and its nerve inadequacy. By perseveringly stimulating proper oxidation a patient is soon able to tolerate in the stomach without fermentation a large enough meal amply to nourish him for a period of four to five

hours. The error of feeding oftener may be brought home by thinking of the modern practice which forbids even infants to be fed oftener than once in three hours. Prolonging the intervals is the best preventive of food fermentation.

FIRM FOODS REQUIRED: CAUSES OF BOLTING.

Of course, some of the food, at least, should be of firm consistence, so as to demand vigorous mastication in order to stimulate salivation. This prevents the bolting of food, a habit to which nervously impulsive persons are liable. Sometimes this habit has been bred in childhood because of the child's haste to finish his meal in order to play. The acquisition of this habit is much facilitated by a soft or pulaceous type of food, such as is so commonly employed nowadays. To bolt a hard crust is impossible, and a piece of tough meat most unpleasant.

The habit of bolting food is part of a vicious circle, for it leads to mal-assimilation, which causes nervousness, which leads to impatience, which favours the bolting of food. The remedy is simple enough: it is to eat dry and hard foods, or, failing that, to master the weak impulsiveness which permits one to bolt.

SPECIAL INDICATIONS: AVOID FORMULÆ.

In prescribing special diets, rigidity should be avoided. A narrowly restricted diet may be felt monotonous and breed disgust, which may produce a psychogenetic dyspepsia in a susceptible neurotic. The patient should be explained the principles on which he must diet himself. If he is uninformed or unintelligent a list of substances may be given him in addition. But even then, the rationale of what he is to follow should be explained. The ready printed lists of certain textbooks, specialists, and pharmacists are an abomination no better than the ready-made prescription. Just as he who is trained in pharmacology will prescribe to fit the patient, instead of making the patient fit an arbitrary prescription, so he who is trained in dietetics will diet each patient, and not make the patient accept an empirical list obtained from the fancied authority of some publication.

This does not mean the negation of all rules. I conclude, therefore, by considering some neurological conditions in the treatment of which dieting is essential to success, and by setting down the nature of the diet suitable to each.

The differences between the diets in these conditions are very small. This, however, only accords with the fact that the human organism as a biological unit functions best when the various types of food which constitute its pabulum are proportionate to one another in a ratio which is pretty definite for the healthy human being.

Now, as pathological states only represent an organism's reaction to noxious influences the optimum diet for good health when in health is only rarely to be departed from, even in diabetics, where this departure is perhaps the widest of all, the prognosis becomes favourable inversely as the necessity of departure from the carbo-hydrate standard of the normal human being. In adiposity, too, the fallacy of disproportionate abstinence from carbo-hydrates and fats is now seen.

DIET FOR EPILEPTICS.

With this understanding, then, consider in the first place the diet in epilepsy. I shall not consider such symptomatic epilepsies as arise from coarse lesions of the brain, or those which occur in cases of defective development; although even in these favourable diet can mitigate the patient's lot. While we believe that epilepsy is fundamentally toxicogenic, yet we do not know whether it is manifested because of increased cerebral susceptibility, or whether it occurs because of weakened defences against the absorption or neutralisation of food toxins. Practically, however, it is clear that most patients are benefited and many cured if, before it is too late, a diet is imposed which minimises the work of the metabolism of proteins more especially during the subsidence of the vital activities during sleep. This diet should, at the same time, facilitate rapid exchange by an abundance of the saline constituents of the diet.

Empirically, it has been known how favourable to such patients is an abundance of fruit and vegetables and a restriction of meat. But failures in the application of diet of epileptics occur unless other proteins than meat are not restricted also; and unless the fruits and vegetables are chosen for their saline quality. Thus, an epileptic fed upon potatoes, eggs, milk, and tasteless fruits would be, perhaps, even worse off than one on the average mixed diet. The diet I recommend is somewhat as follows:

On rising, half a glassful of hot water containing 10 grains sodium bicarbonate.

Breakfast: Large plate non-acid fruit with cream; large plate cereal and milk; toast; no coffee, tea, or chocolate.

Dinner: No meat soups or gravy; 4 ozs. well-cooked meat or two eggs, large plate green or succulent vegetables, potatoes, not greasy; sweets, no gelatine.

Supper: Similar to breakfast, but macaroni or other paste or rice pudding may be taken for cereal, and one egg may be taken also. Graham bread thrice weekly. Distilled water to be taken freely between meals.

At night: Half a glassful of hot water containing 30 grains potassium citrate.

The chlorides of the average diet should be restricted. They are apparently harmful to those prone to epilepsy; for although the hopes aroused by the first recommendation of their deprivation have not been realised; yet many arrests of fits have occurred under a salt-free diet. When it is remembered that a chlorine balance is well maintained by daily ration of $1\frac{1}{2}$ grammes, that the amount in the usual diet is 10 grammes, and that where renal inadequacy exists, œdema quickly supervenes when the excretory capacity of the kidney is exceeded, it should be evident that reduction of common salt is a rational procedure in a disease where cerebral œdema has been found so frequently as 22 per cent. of cases operated in. Some authorities attribute the comparative advantage of milk to its poverty in sodium chloride.

DIET AGAINST ARTERIO-SCLEROSIS AND PRESSOR EXCESS. (a)

A potent cause of nervous inadequacy is arterial hypertension. The rôle of diet in producing this seems to be important. Both purins and excessive nitrogen seem to lead to the formation of pressor substances. Whether they do so by increasing the activity of the adrenal glands is unknown; but it is an explanation to be thought of in connection with this state, which is so frequently found in late middle life. It is often misnamed neurasthenia.

When the renal in addition to the hepatic function is diminished, nervous symptoms as the result of an unwise diet are even more apt to declare themselves; so that the regulation of the diet, then, is of even greater importance. The milk commonly given as the basis of an adult diet is unwise. In the first place the nitrogen content of cow's milk is disproportionate, and it is poor in iron and some other mineral elements. In the second place, it does not demand mastication and the relish which comes with this.

DIET IN CASES OF DRUG ADDICTION.

The craving for morphine or alcohol has often a basis in metabolic disturbances due to a diet or manner of eating which, though usual enough and without apparent injury to the average person, is yet highly injurious to the person in question. I believe that relapses after successful sanatorium treatment are frequently due to neglect of this factor.

THE PERIOD DEPRESSIONS AND EXCITEMENTS, CYCLOTIC AND MANIC-DEPRESSIVE PSYCHOSIS.

The lack of more extensive data regarding the dietetic factor in these cases is regrettable. For the rôle of diet as the exciting cause, and the means of cure in the subjoined case is most impressive.

CASE.—*Recurrent Mania from Gluttony.*—S., the wife of a clergyman, was seen at the York Retreat during my residence there in 1907. For several years she had recurrent attacks of excitement with rise of

temperature, rapid pulse, disorderly acts, filthy ways, obscene language. These would occur at the menstrual period, but only every month, and sometimes less frequently. Preceding and during the attack the leucocytes in the blood were greatly increased. On one occasion 37,000 to the cubic millimetre were found. During the subsidence of the attack, in about ten days, the count would be normal. Between the attacks the patient might be regarded as normal, although her disposition was somewhat selfish and unreliable. No cause for her attacks had been discovered. The patient had been, two years before, placed upon a strictly vegetarian diet without any benefit; for the principles embodied in this article had not been duly considered in the prescription of the diet.

In the search for a cause, I one day minutely questioned a nurse concerning the habits of this patient, who, on account of the freedom given her between attacks, was not under continuous observation by anyone. I was told that she spent her afternoons in passing from one pavilion to another, taking tea in rotation with the nurses. On each occasion she would eat abundantly of what was on the table, and this would go on most of the afternoon. Moreover, she would spend all her money on sweetmeats, and often more substantial things, which she would eat during the morning, seldom offering any to another person.

From these data I theorised that her maniacal attacks were the expression of the outburst of accumulated toxicosis, due to her gluttonous habits. They were precipitated by the toxic wave of the menstrual period; but they did not occur every month, because during the maniacal attacks the patient was practically starved, and insufficient time elapsed before the next menstruation to allow of sufficient accumulation to produce toxicosis.

Whether these were secondary effects of bacterial action, the defence against which was broken down by the excess of food, or whether they were purely biochemical in mechanism, we did not determine, for we were primarily concerned with practical therapeutics. The result fulfilled the expectations of the theory, for the patient's indulgence was prevented, the attacks ceased, she returned home, and my latest advice a year ago was that she remained well.

In a case of recurrent confusion with delirium, referred by Dr. Heiberger, where saburral tongue was marked, improvement did not occur until the diet was reduced to one exclusively of abundant fruit and only three glasses of milk per day.

In another case of recurrent mental confusion, referred by Dr. William Mason, improvement was *pari passu* with the reduction of nitrogen in the diet. Each time an increase was attempted the confusion and delirium returned.

PSYCHASTHENIA.

The sense of incompleteness or inadequacy which is the basis of psychasthenic manifestations has, I believe, often other origin than the psyche. Even the *angoisse*, that prominent emotional characteristic, may not be psychogenic. A general uneasiness may be purely physical in origin.

Scherbak's case, where psychasthenia was provoked several times by caffeine, is an example. Likewise is that of a child of two years, which I reported to the Society of Psychology of Paris, and later published in *Pædiatrics* here. I have noted several times recrudescence of symptoms in psychasthenia after errors in diet. Either starvation or excessive protein aggravate the symptoms. Of course they do not create psychasthenia; but they lower what Janet calls the psychological tension, which thus permits the mental vagaries so characteristic of this disease.

The dietetic poisons, of course, are badly tolerated by such patients, who should abstain from tea, coffee, cocoa and alcohol, which not only disturb nutrition, but interfere with neuronal activity.

"NERVOUS CHILDREN."

The difficult psychic management of the unstable child may be completely vitiated by want of care in very simple dietetic needs. Starvation, too frequent

(a) See *Va. Semimonthly*, 1911; *Transactions Am. Therapeutic Assoc.*

meals, too heavy a ration, excess of protein or extractives, all subtract energy from the cerebrum, where it is needed for discipline. Toxins and peripheral irritations are not conducive to mental activity or emotional tranquillity.

HYSTERIA.

Although the disorders we term hysterical are purely psychological in origin, yet the hyper-suggestibility on which they depend varies greatly with physical states. Diet has a marked influence on these. In the psychomotor discipline against hysterisability, disturbances due to faulty diet are a great handicap. A case may well be ruined by failure of due attention, without which the best psychotherapy may be unavailing. Illustration is afforded in the cases I cite.

A case of hysterical spasm, where psychomotor discipline was unavailing until a faulty diet was rectified, has been recently reported by me in *Surgery, Gynaecology, and Obstetrics* for March, and *Washington Medical Annals* for January, 1912.

A case where hysterical absences were much aggravated by lapses from a strict diet was that I reported in *International Clinics*, Vol. III., 1908. The moody behaviour of this patient could be controlled by psychotherapy only when this was not interfered with by the handicap of neurones below the highest efficiency procured by what was the antithesis of that advertised upon in "Love's Labour's Lost," when Shakespeare makes Fernando say: "Fat jaunches make lean pates, and dainty bits make fat the ribs and bankrupt quite the wits."

Psychotherapeutic re-education demands the wit of patient as well as of physician. A psychotherapy which permits sick minds to become more so by leaning upon the suggestions of another is a poor thing.

When the energies are deployed towards metabolic disposition, large quantities of nutriment are unavailable for concentrated mentality. As an exalter of suggestibility, feasting is as vicious as fasting. Of both means, the old religious organisation were well aware empirically in managing the devotees.

HEMICRANIA AND OTHER CONSTITUTIONAL HEADACHES.

Most of these cases appear to be toxic. It is certain that the vast majority are greatly ameliorated by diet which enforces the principles just described. Even when a psychogenic factor is manifest, the bettering of an unfavourable diet may remove at least the headache from the sufferings of such patients.

An instance is that of a young woman whom I saw with Dr. J. S. Dye, at Chattanooga, in October, 1911. Headaches, which apparently nothing could prevent, were brought on by recurrent painful psychological situations beyond medical control. In spite of the continuance of these, the headaches were prevented after about two months of the special diet I recommended.

Perseverance, however, is often needed. Charles Mercier goes the length of saying that by faithfully following instructions for six months every case of metabolic headache is curable.

When the blood pressure is considerably raised the effect is particularly favourable. Such a case I saw with Dr. S. S. Gale, at Roanoke, November, 1911. A very stout, middle-aged woman had suffered intensely for almost two years with constant and violent headaches. On account of her stoutness, carbohydrates had been restricted for some time. I advised, on the contrary, a restriction of the proteins. The consequence was vast improvement as regards headaches, without increased adiposity.

Headache complicating other affections is susceptible of the same treatment. Thus, a middle-aged woman referred by Dr. Davis, of Washington, for writer's cramp, and who was cured by psychomotor discipline, as described in *Journal für Neurologie und Psychiatrie*, suffered also from periodical hemicrania, which interfered with her treatment. This was very rapidly removed by the proper diet I have described.

I have not succeeded, however, in curing every case, as Mercier believes possible; but perhaps my diagnosis has been in error when the treatment has failed, and an organic cause I could not detect has been present.

NERVOUS DYSPEPSIA.

The majority of such cases, where organic changes

have not been overlooked, are in reality mental or emotional in origin. They are phobias of hysterical or psychasthenic type usually. Hence dietetic insistencies only aggravate them. A wise psychotherapy teaches them to put their stomachs out of their heads. Stomach specialists are tempted to ignore this feature of such cases, which require a careful analysis of their minds rather than of their stomach contents.

A NOTE ON THE BACTERIOLOGY OF THE UTERINE CAVITY IN FIBROMYOMATOUS DISEASE.

By C. H. S. WEBB, M.B., B.S., F.R.C.S.,
Surgical Registrar to the Middlesex Hospital.

THIS investigation was undertaken with the object of ascertaining whether micro-organisms were present with any frequency in the uterine cavity, or in the cervical canal, when the uterus was the seat of fibromyomata; and whether such organisms, when present, coincided with the occurrence of complications, either pre- or post-operative.

Pre-operative complications, or the complications to which the uterus and its adnexa are liable, due to the presence of "fibroids," may be arranged under three headings—viz., (1) hæmorrhage; (2) the results of infection; and (3) mechanical effects. The last group comprises such phenomena as impaction, obstruction to labour, pressure effects, e.g., on the bladder or intestine, axial rotation, etc., and are not of direct interest here. On the other hand, hæmorrhage and sepsis might conceivably be due to the presence of organisms demonstrable in the uterine cavity or cervical canal.

Bland-Sutton, in his work on "Tumours," states that the most serious hæmorrhages from uterine fibroids are associated with septic changes in the tumour, so that, in considering septic changes, one is also considering the hæmorrhages to which such changes give rise. Infection may be considered in its relation to (1) the tumour, and (2) the uterus and its adnexa. Infection of the tumour may result in necrosis and gangrene, with sloughing, and possibly extrusion of a small sub-mucous fibroid. The infection may extend to the uterine mucosa, and may ultimately give rise to a peritonitis *via* the Fallopian tubes and abdominal ostia. These changes are met with almost invariably in the sub-mucous variety, and result, according to Bland-Sutton, from extrusion of the tumour into the vagina, where it is exposed to the attacks of micro-organisms, and possibly rendered less able to withstand invasion by reason of the venous congestion induced by constriction at the external os uteri.

Other complications are hydro- or pyo-salpinx, while occasionally "fibroids" may be complicated by ascites. The red degeneration, commonly associated with pregnancy, has been shown occasionally to contain a staphylococcus albus by Hastings.

Some Continental observers believe that complications occur with much greater frequency than would seem to be the experience of English surgeons. Constantin Daniel, in a paper in the "Revue de Gynécologie" on the state of the adnexa in uterine "fibroids," has collected most of the literature. But although he enumerates a long list of complications (pre-operative), yet he does not mention the name of a single micro-organism. On the other hand, he goes so far as to state that, "in the end bacteriology confirms microscopical examination, inasmuch as the examination of the cavity or the mucosa as carried out by Winter, Döderlein, and Wertheim, has never led to the identification of the micro-organism." And again, "it follows from what precedes, . . . that the 'so-called endo-metritis of fibroid uteri' of Swartz and Hepp could only be an aseptic endo-metritis, a nutritional alteration, which proceeds *pari passu* with the proliferation of the rest of the uterine parenchyma." He concludes that septic infection plays a very small part in the pathological findings in the mucous membrane of the uterus and tubes, and believes that mechanical causes are sufficient to produce the changes found (*métrite et salpingite*). He

quotes Jones of Boston as saying that "he has found the adnexa to be diseased in every case of laparotomy for fibromyomata that he (Jones) had performed."

But in spite of such sweeping assertions, no mention is made of any micro-organism by name, nor is any account given of attempts to isolate organisms from such cases.

Of the post-operative complications conceivably due to the presence of organisms inside the uterus at the time of operation, hæmorrhage (secondary), peritonitis, and possibly thrombosis are of general interest, while of more special interest may be mentioned a vaginal discharge, persisting for some time after the operation. This discharge is often due to an infected suture in the stump of the cervix. This may be so troublesome as to necessitate the patient submitting to a further operation.

For these reasons it was thought of interest to examine bacteriologically the uterine and cervical cavities in a series of sub-total hysterectomies for fibromyomata, a series, however, if judged by the findings of Jones of Boston, remarkable for the paucity of complications found at operation.

The method of examination was as follows:—Immediately after the amputation of the uterus two sterile swabs were passed from above into the cervical canal in the stump of the cervix left in the pelvis. One of these was used to make film preparations, the other to inoculate a series of culture media. The amputated uterus was received into, and carefully covered by, a sterilised towel pending examination. The surface judged nearest to the uterine cavity, and as near the fundus as possible, was seared with a hot knife, and the cavity then opened; culture media were inoculated and film preparations made. (a)

Ten cases were examined and were not picked or chosen in any way. Seven cases were absolutely sterile (both uterine cavity and cervical canal), while in three cases organisms were isolated—in two instances from the cervical canal, and in the other from the uterine cavity. In tabular form the results were as follows:—

Case.	Uterine Cavity.	Cervical Canal.
I.	Sterile	Sterile
II.	"Colon-Group" Bacillus (sporing)	Sterile
III.	Sterile	Bac. coli.
IV.	Sterile	Döderlein's bacillus.
V.	Sterile	Sterile.
VI.	Sterile	Sterile.
VII.	Sterile	Sterile.
VIII.	Sterile	Sterile.
IX.	Sterile	Sterile.
X.	Sterile	(Not done.)

The organism isolated from CASE II. (body) produced turbidity in broth, inoculated from the uterine cavity, in twenty-four hours. The remainder of the tubes remained sterile. The organism was a + Gram, motile, rod-shaped bacillus, producing indol in broth, coagulating milk and digesting the clot. A broth sub-cultured was heated to 60° C., sub-cultured on to agar-agar and gelatin, and the organism recovered from these, showing that spore formation was present. Probably this organism was non-pathogenic, possibly a contamination.

From CASE III. (cervix) a pure culture of bacillus coli was obtained, conforming to all the general tests for that organism. Here again the presence of the organism was probably accidental, as in opening the abdomen at the operation a piece of small intestine was inadvertently wounded, and had to be sutured before the uterus was amputated.

The organism isolated from CASE IV. (cervix) was Döderlein's bacillus. Discrete colonies appeared on the blood-agar culture on the fourth day. The

(a) Identical series of culture media were used for body and cervix, and comprised gelatin slope, agar slope, blood-agar slope, glucose-agar stab, and peptone broth. The blood agars were made freshly for each case, and included a control tube. The glucose-agar stab cultures were covered in with melted agar-agar, and used as anaerobic tests. The tubes were incubated and examined after twenty-four hours' incubation, when, if no growth were apparent, they were "capped," re-incubated for a fortnight, and examined for growth daily during this period. If no growth had taken place at the end of the fortnight they were accounted sterile.

organism was a large rod-shaped bacillus with a tendency to be curved, non-motile, and staining by Gram's method. Sub-cultures were successfully made on to ordinary agar-agar and blood-agar in broth and litmus-milk, but unsuccessfully on potato. In litmus-milk an acid reaction occurred in twenty-four hours, and a flocculent coagulum appeared in forty-eight hours. A rabbit and a mouse were inoculated, but showed no signs of infection, and were alive and well ninety-six hours after.

I have been unable to find any description of this organism either in those monographs of Döderlein's quoted in the English text-books, or a complete description in any one of such text-books, but a fairly complete description is found in Blair Bell's Gynecology, and has been supplemented from Eden and Howard Kelly.

The organism called the vagina or Scheiden bacillus, is a rod-shaped organism, normally inhabiting the vagina and secreting lactic acid, which Döderlein thinks causes the acid reaction of the vaginal secretion. Interesting experiments have been carried out by Menge, who found that the bactericidal power of the normal vaginal secretion is very marked, and that pyogenic organisms introduced are rapidly killed. Blair Bell also states that the uterus is normally sterile. Eden states that this "Scheiden bacillus of Döderlein" is found in the white, flaky, acid secretion from the vagina in children and healthy pregnant women, that it grows only in acid media, and that lactic acid can be found in the secretion when it is present. He goes on to remark that it probably plays a protective rôle, antagonising the pyogenic cocci, either destroying them or paralysing their activities.

The following is a list of the cases, with a brief abstract of the notes. The operation performed in every case was sub-total hysterectomy:—

CASE I.—C. F., æt. 43, married, housewife. Duration of "lump," two years. Menorrhagia and metrorrhagia slight. The uterus contained several sub-peritoneal fibromyomata. There were no complications present at the operation, and none occurred after operation, the patient making an uninterrupted recovery.

CASE II.—A. F., æt. 25, single, teacher. Pain in the back a periods for last twelve months. No tumour felt per abdomen. Menorrhagia not marked. There was some metrorrhagia; that occurring immediately after the periods was offensive. No complications present at operation, and none other after operation than a somewhat elevated temperature (99°—101°), not becoming normal till the eighth day. There was no vaginal discharge after operation in this case.

CASE III.—L. C., æt. 27, married, housewife. Pain in abdomen for six months before operation. Some menorrhagia and metrorrhagia, the latter offensive three days before periods. During the operation a piece of small intestine was wounded in the opening of the abdominal wall.

The dressings on the second day after operation were stained with bright blood, and some blood oozed through the cervix into the vagina.

The highest temperature was 100.4° F., on the evening of the second day after operation. The temperature was not quite normal till the fourteenth day after operation, varying between 99° F. and 100° F.

CASE IV.—(Döderlein's bacillus.) G. D., æt. 46, married, housewife. Tumour noticed first three years ago. No menorrhagia or metrorrhagia. Some frequency of micturition. Complained of headache on the third day after operation. The temperature remained high, varying from 99.8° to 101.4° until the twentieth day after operation, when the abdomen was found to be distended, rigid and painful, and dull above the pubes. Under an anæsthetic an incision was made in the posterior vaginal fornix, and 22 oz. of offensive blood liberated.

The temperature immediately fell to normal, and the patient made an interrupted recovery.

Döderlein's bacillus was isolated in pure culture from this blood.

CASE V.—(Sterile.) E. W., æt. 37, single, unem-

ployed. Menorrhagia and metrorrhagia commenced three years ago. The metrorrhagia was slight and somewhat offensive. Nothing noteworthy about the operation. After operation the highest temperature (100° F.) occurred on the eighth day, and was normal on the ninth day, but on the fifteenth day it shot up to 100.2° F. again, coinciding with the occurrence of a thrombus in the left leg. Otherwise an uninterrupted recovery.

CASE VI.—(Sterile.) A. R., æt. 33, married, housewife. Three weeks previous to operation patient was delivered of a full-term child, and had been running an evening temperature varying between 99.8° F. and 100.6° F. This, after operation, came down to normal on the evening of the second day. She then made an uninterrupted recovery.

On account of the pre-operative temperature it was deemed extremely likely that organisms would be found in the uterine or cervical cavities, and in consequence the examination was made with every care, but proved negative.

The remaining four cases were all sterile of organisms, and presented no features of interest either before or after the operation.

CASE VII.—(Sterile.) E. H., æt. 42, single, house work. Menorrhagia for eighteen months. Temperature, after operation, normal on fifth day. Uninterrupted recovery.

CASE VIII.—(Sterile.) M. M., æt. 40, married, housewife. Menorrhagia for two years. Tumour noticed for one year. Leucorrhœa for last six months. Here, again, although leucorrhœa was present, no organisms were found. Temperature normal after operation on fourth day. Uninterrupted recovery.

CASE IX.—(Sterile.) M. H., æt. 30, single, maid. No duration given in notes. The fibroid was of the cervical variety. Temperature normal on fourth day after operation, and patient made an uneventful recovery.

CASE X.—(Sterile.) M. P., æt. 41, single, parlour-maid. Tumour noticed four years ago. No menorrhagia or metrorrhagia, in association with which it is interesting to note that the tumour was a sub-mucous fibroid and was very large. There was a good deal of hæmorrhage during the operation, and for this reason it was not deemed advisable to prolong the procedures by taking swabs from the cervical canal; the uterine cavity alone was therefore examined.

The temperature was normal on the sixth day, and the patient then made an uninterrupted recovery.

From a consideration of the table it will be seen that seven out of the ten were absolutely sterile, while in two of the three cases in which organisms were found their presence can most probably be explained as contaminations. For instance, in Case II. the organism showed definite spore formation, which is enough, in conjunction with its other characteristics, to class it as non-pathogenic, and probably therefore a contamination. (a)

It may possibly have been living a saprophytic existence in the uterine discharges, and the history that the metrorrhagia was offensive is in favour of this.

In Case III. a pure culture of bac. coli was isolated from the cervical swab, but the operation was complicated by the wounding of a piece of small intestine.

As regards post-operative complications, these were present in three cases—viz., III., IV., and V. Case II. (sporing bacillus) displayed a somewhat elevated temperature after operation, not reaching normal till the eighth day, not, however, at any time very high (99° F. to 101° F.), otherwise it presented no abnormal features. Case III. (bac. coli) was marked by secondary hæmorrhage, which made its way out through the cervical canal, and also through the abdominal wound. The temperature remained slightly elevated, not remaining normal until the fourteenth day after operation.

(a) The only pathogenic rod-shaped bacilli which produce spores are: tetanus, anthrax, malignant œdema, and bac. enteritidis spirogenes. The pathogenic members of the colon group to which the above organism was most closely related do not form spores.

Case IV. (Döderlein's bacillus) had well-marked secondary hæmorrhage, enough to form a pelvic hæmatocele containing 22 oz. of offensive blood, from which the organism was again isolated. The temperature here remained isolated (99°—101.4°) until the hæmatocele was evacuated on the twentieth day; after this it immediately fell to normal.

Case V. was complicated by a thrombus in the left leg. No organism was isolated in this instance.

The other six cases made perfect and uneventful recoveries, and in none was any organism found.

Generalisations from a series so small as the present are apt often to be erroneous. The most that can be said is that in the majority of cases of uterine "fibroids" the cavity of the uterus and the cervical canal are sterile, but that organisms, when present, may produce secondary hæmorrhage, or be the cause, possibly, of an elevation of temperature, prolonged somewhat beyond the period of post-operative or "traumatic" fever met with in the first few days of convalescence from any aseptic major operation, but that complications such as thrombosis may occur in the absence of such organisms.

It seems probable that one may ignore as negligible the danger to be feared from the cut cervix, and that here, as elsewhere, the micro-organisms most to be feared are those introduced at the operation.

COLLOID SELENIUM IN THE TREATMENT OF CANCER.

By M. LAURENT, M.D.;

Physician to the Havre Hospital,

AND

J. BOHEC, M.D.,

House Physician.

WE have under our care a patient suffering from a new growth in the stomach, causing much pain and general disturbance, in which the employment of selenium in the colloid form, in accordance with the procedure devised by M. André Lancien, afforded so much relief, and determined such a marked improvement that the effects appear to us to be deserving of publication. We cannot do better than to give brief notes of the case.

The patient, a man, æt. 41, by profession a blacksmith, stated that he had always enjoyed good health until the onset of his present illness. His mother had died when 57 years of age, of cancer of the stomach, one year after undergoing gastro-entero-anastomosis. He denied having had syphilis, and was not addicted to alcohol, and he had been strong and robust until October, 1911.

His troubles began, without obvious cause, with acute severe stabbing pain in the epigastrium, which was also felt in the back. This pain radiated towards the hypochondria, and round the waist, and came on half or three-quarters of an hour after eating. It was accompanied by vomiting of food and other dyspeptic disturbances, anorexia, repulsion for fats and meat. The pain persisted between meals in a rather different form, being heavy, continuous, with a feeling of weight. It came on in paroxysms with exacerbations, followed by the vomiting of watery, glairy, bilious matter, the attacks of sickness lasting from ten minutes to half-an-hour. These gastric attacks, which were often very severe, were specially pronounced at night, coming on five or six times during the hours of darkness, effectually preventing sleep. He managed, however, to go on with his work until November, 1911, when he was obliged to take to his bed on strict milk diet. The rest and diet afforded him a certain measure of relief, whereupon he returned to work, though in a more or less perfunctory manner, the attacks of gastric

pain forcing him to lay up from time to time. After a time these attacks became aggravated, lasting from half an hour to two hours, or even all day, and especially all night.

On March 30th, 1912, he was admitted to the wards of the General Hospital. Under the influence of rest, diet, and treatment (bismuth, an effervescing mixture, stovaine, Indian hemp, chloroform water, &c.), the intolerance of food subsided somewhat. The patient had never had hæmatemesis or melæna, and the bowels were fairly regular, the stools being blackened by the bismuth he was taking. On examination no actual tumour could be detected, but there was well-marked tenderness over the epigastrium, with some enlargement of the liver. There was nothing to suggest incipient locomotor ataxy and no enlarged glands.

As the gastric crises tended to become progressively more violent, and as their intermittent, paroxysmal character and nocturnal incidence were suggestive of a specific origin, he was given fifteen intramuscular injections of bin-iodide of mercury. He left the hospital at his own request on May 4th, 1912, slightly better, the improvement no doubt being due more to rest and diet than to treatment. He tried to work, but had to cry off two or three days a week, and was constrained to apply for re-admission on June 24th, 1912.

His state was manifestly worse than when first seen. There was obvious loss of strength, and well-marked emaciation, and the intolerable pain from which he suffered was only partially and temporarily relieved by hypodermic injections of morphine. We witnessed some of the attacks, during which the patient writhed on the bed, turning over and over in search of ease. He was put on the same treatment as before—viz., 2 or 3 drachms of carbonate of bismuth a day, with mixtures to relieve the sickness, a further series of biniodide of mercury injections followed by fifteen injections of hectine, but without any tangible benefit.

Clinical examination of the patient and exploration by means of the X-rays revealed the presence of a tumour of the wall of the stomach. After consultation, it was decided to try colloid selenium (seleniol), and a first, intravenous, injection thereof was given on August 15th, 1912. One hour after the patient complained of very severe pain in the pit of the stomach, which was relieved by a morphine injection. In the course of the evening he remarked on the altered character of the pain, which was distinctly less severe. A second injection was given on August 17th, and a third two days later. The usual features of the gastric crisis disappeared during the week, the appetite began to return, and the sickness subsided.

In the course of the following week he was given three other injections of colloid selenium at intervals of two days, and the improvement was not only maintained, but became more marked. The patient recovered his spirits, confidence returned, and he enjoyed good sleep. He still suffered from his stomach now and then, and occasionally brought up his food, but the pain was vague and ill-defined, and the syndrome was no longer that of typical gastralgia. After a week's rest he had four more injections—this time intra-muscular, in the gluteal region, bringing us down to September 15th.

It will be noted that the selenium treatment,

commenced on August 15th and comprising ten injections, had a most pronounced effect in relieving the gastric crisis associated with the existence of a neoplastic tumour of the stomach.

The selenium employed was the electrically prepared Selenium A colloid (André Lancien's process), of which 3 c.c. were injected each time. On some future occasion we shall make it our duty to record the ultimate result of the treatment in this case, which presents the greatest therapeutical interest.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

EXCISION OF PENIS.—MR. T. P. LEGG operated on a farm labourer æt. 70, who had been admitted for an epithelioma of penis, which had destroyed the whole organ to within an inch of its base. The growth had been in existence some months and had produced, as is usual, very few symptoms. The ulcer was of the usual nodular type, with an indurated base and very little discharge. The glands in both groins were considerably enlarged, but not adherent to the surrounding tissues. There were no enlarged glands in the iliac fossæ. The general health of the patient was otherwise quite satisfactory.

The patient was anaesthetised and placed in the lithotomy position; a median incision in the perinaeum was made down to the urethra, which was isolated and dissected back towards the base of the bladder. The urethra was then cut across in such a place that enough of the proximal portion was left to enable it to be brought down without traction to the cutaneous surface of the perinaeum. The corpora cavernosa were next detached on both sides from their posterior attachments. The dissection of these structures was continued forwards until where they passed under the arch of the pubes and joined one another in the body of the penis. After all the bleeding in this perinaeal wound had been arrested gauze packing was temporarily placed in it. An incision wide of the ulcerating growth was then made in the skin of the scrotum and in front of the root of the penis on the lower part of the abdominal wall; in the latter situation the incision was deepened until the sheath of the rectus and the suspensory ligaments of the penis were reached. In the scrotum the whole thickness of the skin and underlying tissues were divided until the corpora cavernosa were exposed. The suspensory ligaments and loose connective tissues around them were divided. The penis and growth were thus entirely separated and were removed by making traction towards the front of the patient's body. The oval-shaped area in the scrotum and the lower part of the abdominal wall was then closed by interrupted sutures; a large drainage tube being inserted at its lower part. It was necessary to do a certain amount of undercutting in the adjacent parts of the abdominal subcutaneous tissues in order to get the edges of the wound together. A somewhat irregular scar resulted. The gauze packing was removed from the perinaeal wound and the edges united by interrupted silkworm gut sutures; a drainage tube being also placed in this wound. The divided end of the urethra was fixed to the margins of the incision, about an inch in front of the anus. Before inserting the sutures a lateral incision about half an inch long was made through the whole thickness of the urethral wall on each side, thus forming an upper and lower flap. Two or three sutures were used to unite each of these flaps to the skin. A soft rubber catheter was then passed into the bladder and fixed *in situ* by a stitch passed through it and the skin.

Mr. Legg said that the operation which he had just performed was the most satisfactory and the only one which could be advised when a growth extended as far back in the penis as in this man's case. The first point to consider is the possibility of eradicating the disease, and this operation is the best so far as recurrence in the penis itself is concerned; there is very

little likelihood of this happening if the surgeon is able to get well behind the furthest limit of the growth in the organ. When the growth is less extensive it is often possible to amputate the penis in front of the scrotum and leave the patient with a stump which he can hold when he desires to micturate. The second point which is always to be considered is the future as regards micturition: it is never advisable to leave the patient with the opening of the urethra just in front of the symphysis pubis or close to the attachment of the scrotum; an opening in this region causes much discomfort, because at every micturition the patient is liable to wet the scrotum and have a good deal of eczema set up. A perineal orifice for the urethra is not open to these objections: it is true a man cannot pass his water in the usual fashion, but the urine is projected downwards between his legs in a receptacle, which can be held there, or on which he can sit. It is not very uncommon for the patient to have some incontinence of urine for a little time after the operation, and after the catheter has been removed, which is generally done at the end of two or three days. But in a very short time the patient regains full control of his bladder. The catheter is put in at the time of the operation to prevent retention of urine. There may be a good deal of swelling about the new orifice of the urethra, and it is not always an easy thing to pass the catheter to draw off the urine under these circumstances. When all the inflammatory swelling has subsided it is easy to pass a catheter into the bladder. The urethra is split, as was done in the operation, to prevent contraction of the new orifice taking place and thereby preventing a stricture forming. If the new opening for the urethra is placed as far in front of the anus as was done in this patient the risk of infection of the urethra or the bladder from the anus and rectum is negligible.

Mr. Legg also pointed out that the operation he had just done differed from that described in text-books in one important respect, namely, that the scrotum was not split through its raphe between the testicles. This was a proceeding which he considered was never necessary, and the operation could always be carried out by making an incision round the base of the penis and deepening this cut until the two wounds were united across the base of the scrotum. Another important point was to do the perineal part of the operation first, and, when the penis and the corpora cavernosa have been completely detached, to push the posterior portions into the anterior part of the wound and thereby avoid infection of the large wound in the perinaeum, which would be likely to occur if the ulcerating and diseased part of the penis were removed by pushing it backwards into the perinaeum. The operation was a severe one, chiefly from hemorrhage; if care was not taken to arrest all bleeding as vessels were divided; if this was done the severity and risks of the operation were much diminished. The removal of the glands in the groin was postponed for a time, as this in itself involved a wide dissection on both sides, and because it was almost impossible with the ulcerating growth on the penis to prevent the wounds becoming infected. Moreover, after the removal of the penis in the manner he had employed had been completed the patient was not in the state to undergo further extensive operative procedures.

The patient made a good recovery.

TRANSACTIONS OF SOCIETIES.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, OCTOBER 24TH, 1912.

The Vice-President, DR. C. J. MACALISTER, in the Chair.

DR. A. J. WALLACE read a note on four cases in which he had performed

HEBOSTEOTOMY.

Two cases were done by the open method six years

ago and had not impressed him favourably, but two recent cases done by the subcutaneous method had given good results; a live child was secured in both cases, of seven pounds in one case, eight pounds in the other; the one mother recovered and left the hospital in 24 days, the other in 17 days. Dr. Wallace illustrated his note by lantern slides, showing the anatomy of the parts concerned, the *technique* of the operation and the results obtained. He thought the operation useful in the minor degrees of contraction where the passages were fully dilated and the child alive. On the Continent the operation had been performed indiscriminately and had had very bad results. Statistics were quoted from various authorities.

Dr. A. A. BRADBURN read a note on

LACHRYMATION,

in which he gave a sketch of the nerve mechanism, and related cases where alteration in the secretion was due to general causes. He protested against the use of dilating probes in cases of overflow of tears.

Dr. G. A. CRACE-CALVERT read a paper on

INTRA-CRANIAL TUBERCULOSIS IN ADULTS.

The paper was based on seven cases, chiefly meningeal. The condition had occurred in males not over 50 years of age, and mostly between 30 and 45. It was always secondary to tuberculous disease elsewhere, especially in the lungs. It had been suggested that the condition was due to the use of tuberculin, but Dr. Calvert believed it had occurred most in cases where tuberculin had not been used. As one explanation of the preponderance of male over female cases, he suggested that men worried more over being ill and were more anxious and irritable than women. The symptoms of the disease were insidious and obscure, and a non-acute type of onset was common. Headache was the most common symptom. Fever was sometimes absent; vomiting was not common and was a late symptom. Constipation was marked, but was possibly due to opiates. Optic neuritis was absent in four out of the seven cases. Kernig's sign was not always present. The pulse was in some cases quick and irregular, but in other cases slow and of high tension. The respiration, slow and shallow to begin with, might become of the Cheyne-Stokes type. In some cases there was retraction of the head. Coma might occur for several days; the patient apparently got well for a time, the coma coming on again, and being fatal even after a month's intermission of symptoms. Diagnosis depended on the severe persistent headache in a subject showing evidence of tuberculosis, especially when accompanied by optic neuritis, Kernig's sign, and mental derangements. Lumbar puncture showed increased quantity of secretion, turbid or clear, an excess of lymphocytes, and in 80 per cent. tubercle bacilli were found. The result was invariably fatal in adults in from nine days to seven weeks. The treatment was symptomatic, morphia being found to give most relief to the intense pain. Lumbar puncture gave temporary relief. The local reaction following tuberculin produced more pain; so far no good results had followed.

In the discussion that followed Dr. C. J. MACALISTER said he had seen relief from the use of wet cupping over the parietal protuberances, and in children recovery after the use of mercurial inunction.

Dr. W. PERMEWAN questioned the justifiability of the use of tuberculin, as it seemed to him that intra-cranial tuberculosis was so frequent where that remedy had been used.

Dr. J. HILL ABRAM thought lumbar puncture was not needed for diagnosis, and he disapproved of its use if a general anaesthetic were required, as the psychical disturbance had a bad effect on the patient, and the method frequently gave no positive result. He quoted a case of intra-cranial tuberculosis that had apparently been cured by tuberculin.

Dr. LLOYD ROBERTS spoke of temporary aphasia as an early symptom in these conditions; he had seen three cases.

Dr. R. J. M. BUCHANAN described the method of using tuberculin at the Kennington Dispensary, where

the lobing of leucocytes was taken as the indication for the dosage.

Dr. PERCY MARSH had found among children that lumbar puncture gave no result, the relief of symptoms being only very transitory. Tuberculin had proved of no use.

Dr. T. R. GLYNN, Dr. W. B. WARRINGTON, Dr. W. D. WILKINS, Dr. FAIRFORD THOMAS, Dr. C. RUNDLE also took part in the discussion, and Dr. CRACE-CALVERT replied.

HARVELIAN SOCIETY OF LONDON.

CLINICAL MEETING HELD AT THE HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE, W., ON THURSDAY, OCTOBER 17TH, 1912.

The President in the Chair.

The following cases were shown:—

Dr. LEONARD GUTHRIE: (1) Primary lateral sclerosis. (2) Residual chorea.

Dr. MAURICE SQUIRE: (1) Carcinoma of Breast, treated by X-rays. (2) Keratoderma Blennorrhagica.

Dr. S. L. HAY (for Dr. Wilfrid Harris): (1) Notes on a case of Spinal Tumour. (2) A case of Glossal Tic.

Dr. G. DE B. TURTLE (for Dr. Graham Little): (1) Erythema Multiforme in a boy. (2) Framboesiod Syphilide in a man.

The cases were discussed by Dr. GUTHRIE, Dr. LANGMEAD, Dr. TURTLE, Dr. MAURICE SQUIRE, Mr. BOURNE, Dr. TRAVERS SMITH, Dr. HAY, and the PRESIDENT.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Oct. 26th, 1912.

CITRATE OF SODA IN GASTRIC PAIN.

GASTRIC pain after eating is so frequent that the therapeutic remedies prescribed against it are beyond enumeration. Attributed to hyperacidity, it was generally treated by alkalines, chalk, magnesia, and especially bicarbonate of soda. But if these alkalines relieved the pain they stimulated at the same time the secretion of the hyper-acid gastric juices. According to Dr. Hayem, an authority on gastric affections, certain patients who had prolonged the use of bicarbonate of soda found in the end that it had no longer any effect on their suffering. Citrate of soda, employed for the first time in England by Dr. Wright, was recently introduced into France and prescribed with great success in gastric intolerance of children.

Dr. Lacheny, who made it the subject of his thesis, describes how citrate of soda relieves gastric suffering coming on three or four hours after meals. In all the cases he observed the salt promptly relieved the pain, while it had a remarkable curative effect on the morning vomiting of habitual drinkers. The efficient dose is from half to one drachm. As to its mode of action, Dr. Lacheny concluded that the salt combining with the free acid was resolved into citric acid and chloride of sodium, and that the sedative action was due to the soda. The solution of citrate of soda should be freshly made, as it loses its properties after a few days.

TREATMENT OF PSORIASIS.

The diagnosis of psoriasis is easy: its slow evolution, its dissemination, its predominance on the surface of extension of the limbs (knees, elbows), its aspect, removing all doubt.

The characteristic signs of the eruption are known to all.

The treatment is long and requires great patience and perseverance on the part of the patient, otherwise the affection returns rapidly.

Arsenic, says Prof. Gougerot, should form the

basis of the treatment either in the form of arrhenal or Fowler's solution:—

Arrhenal, 15 grs.

Water, 4 oz.

A teaspoonful at the midday meal and continued 20 days; after a suspension of 10 days it is repeated, and so on every month.

As Gaucher has shown that there is a great loss of chlorides during the course of the malady, re-mineralisation is necessary:—

Carbonate of lime, 6 gr.

Phosphate of lime, 10 gr.

Cal. magnesia, 2 gr.

Chloride of sodium, 2 gr.

For one powder; two daily, after meals.

Digestion should be facilitated by taking a large glass of the following solution before meals:—

Bicarb. of soda, 2 drs.

Phosphate of soda, 1 dr.

Sulphate of soda, ½ dr.

Water, 1 quart.

The local treatment recommended by Prof. Gougerot consists essentially in the application of cade oil:—

Oil of cade, 4 oz.

Black soap, q.s.

Oxide of zinc, 4 oz.

Olive oil, q.s.

The whole body is coated with this paste on going to bed, the patient wearing a flannel shirt and tight drawers, which should be kept on during the whole period of treatment.

In the morning this paste is removed with vaseline and then by soap; a bath is taken immediately after, either with cade oil bath or, if not possible, an alkaline bath.

Oil of cade, 4 oz.

Black soap, 4 oz.

to be poured into the bath.

If the patient has to go out in the day no ointment is put on, but if he can keep indoors the paste may be used.

For the head, neck and face the ointment of Prof. Gaucher should be substituted for the paste:—

Sulphur, 15 gr.

Salicylic acid, 15 gr.

Camphor, 15 gr.

Oil of cade, 3 dr.

Oxide of zinc, 5 dr.

Vaseline, 8 drs.

The treatment should be carried out under the control of the medical attendant, who should be careful to look for symptoms of irritation of the skin due to the oil of cade.

As soon as the lesions are found to be improving and that the isolated patches have disappeared, a less anæsthetic treatment may be applied.

GERMANY.

Berlin, Oct. 26th, 1912.

At the Naturforscher-Versammlung-Department for Surgery, Hr. Vorschütz, Cöln-Lindenberg, gave an address on *Die Bedeutung der Alkalis in der Behandlung der Sepsis*.

THE IMPORTANCE OF THE ALKALIS IN THE TREATMENT OF SEPTIC DISEASES.

In the fight against inflammation the blood furnished the most important factor in the strife. This factor, according to Buchner, was dependent on the salts in the blood, as with a diminished alkalescence the bactericide property of the blood diminished also. According to recent inquiries the alkalescence of the blood was diminished in all infective diseases. Now, proceeding from this standpoint, as much as four years ago, patients suffering from serious infective diseases and inflammations had been treated with a copious supply of alkalis in the form of Na_2CO_3 in doses of from 20 to 25 gm. for adults and 10 gm. for children. The administration was best effected in artificial carbonic acid water, or per rectum, as in the large intestine 75 per cent. of the alkali was absorbed. The striking part was that in all the patients, in spite of the worst possible general condition there was at once a feeling of well-being and the mental faculties did not

become clouded, they retained consciousness. Patients in whom the prognosis was most unfavourable recovered. In the consideration of these cases we were thrown on to our clinical experiences, which under certain conditions were as valuable as theory and experiment. The speaker had attempted to show by experiment that the administration of the alkali exercised a certain influence on the infective process. He would like to show that the body with acidulated blood was not in as good a position to un-poison the system as normal alkaline blood. The experiments were made with ricin. Experiments had shown that 0.1 gm. pro kilo of body weight was an absolutely fatal dose for rabbits. The blood was made acid by 1/10 normal hydrochloric acid solution, of which 50 c.cm. were injected into the jugular vein. The rabbits which averaged a weight of 2 to 2½ kg. bore this without the least effect being traceable. When these animals were given ricin in doses that were not otherwise fatal, after a time they died, the acidified blood was not capable as normal blood was of un-poisoning, when equal doses of toxin were given. If this view was correct, animals that were given a similar dose of ricin and hydrochloric acid should remain alive when the acid was neutralised by a corresponding dose of alkali. This neutralisation was effected by injecting, also into the jugular vein, 50 c.cm. of a 1/10 normal solution of soda. The technical difficulties here were very great and in only one case could any definite result be obtained. The experiments, however, supported the assumption that the poisoning was dependent on diminished alkalescence. As regarded the action one might assume that the alkalies within the body took on the rôle of catalysators, by virtue of which the individual cells were in a position to form protective ferments.

On the basis, therefore, of clinical and experimental experiences the speaker would recommend that in severe forms of inflammation the administration of alkalies should be carried out from the commencement. In chronic suppurations also, which frequently show the typical appearance of "drying up," the use was commendable.

Hr. Kausch, Berlin, asked if the course in several severe cases was typical and particularly whether the curve of the excretion of albumen was always the same as in the case of scarlatina sepsis shown, whether in the experiments on animals an acid poisoning did not play a part?

Hr. Vorschütz said that a number of severe cases of the most diverse kinds had recovered. The possibility of acid poisoning was excluded by preliminary experiments.

Hr. Tilmann, Cöln, pointed out again the striking subjective well-being of patients in the severest diseases, and more than all he had never seen the slightest harm from giving the alkalies.

NEW ROENTGEN INSTITUTE.

On the 7th inst. a new Roentgen Institute was opened in Berlin which had been recently erected by the Central Committee of the Krankenkassen Berlins and suburbs. It stands near the Hydrotherapeutical Institute erected a few years ago by the same authority, where the attendance amounts to about 200 patients a day. Both establishments are under the direction of Dr. O. Keiserling and Dr. Kapferer. The Institution was erected by a Munich firm at a cost of 10,000 M. It is fitted with the newest and most approved forms of apparatus, and is intended to be employed for all the different divisions of service in which the X-rays find employment.

AUSTRIA.

Vienna, Oct. 26th, 1912.

POLIOMYELITIS.

STARKE, in his clinical lecture, commenced with a history of the disease as an inflammation of the grey matter in the anterior horns of the spinal cord that led to muscular paralysis, atrophy, loss of reflex, associated with degenerative reaction. It was first recognised as a child's disease, a child being more

sensitive to spinal disease. In 1840 Heine first described the disease, although Underwood described the same symptoms under the title of dentition paralysis, but Heine first defined the site of lesion. Clinical testimony was next forthcoming by Duchenne's electro-diagnosis, which Cornil confirmed by pathological anatomy in finding the horn smaller and the ganglionic cells wanting in the anterior horns, which Clarke subsequently confirmed. Charcot next endeavoured to discover the cause of this change, and decided that it was an inflammatory condition of the ganglionic cells which, with subsequent atrophy, was the initial order of the disease. He designated the morbid process as "parenchymatose inflammation of the grey substance of the cord." Kussmaul, with many others, confirmed the histological findings with changes in the vascular supply and cell infiltration in the walls of the vessels.

In 1883 Archambault and Damuchina controverted Charcot's opinion of origin in the ganglionic cells, and affirmed that it was due to an interstitial myelitis. Up to this time it was recognised as a child's disease, but Meyer met with the disease in two young men, 18 years of age, after an attack of measles, which encouraged him to affirm that adults, after exanthematous fever, were subject to the same disease.

Duchenne looked upon the pathology as a nerve disease. He met with four cases with all the phenomena of children's spinal disease, which he described as *spinale antérieure aigue de l'adulte*, and a sub-division which he termed *sub-aigue*, the latter being a sub-acute form or chronic, as their course ran on for weeks or months before the paralysis of the extremities took place and the atrophy of the muscles showing the degenerative phenomena.

The following is a picture of the disease, commencing without any severe phenomena and apparently without any cause. A healthy man observes one of his arms or legs becoming weak, the weakness increasing day by day for a few weeks, till it becomes so troublesome that he cannot make use of the affected extremity. The weakness may then extend to another arm or leg, affecting the hip, neck, or muscles of the face. The paralysis will always be observed to have an elective character, affecting muscular groups, which the patient observes to become smaller by atrophy and having a degenerative reaction.

The sensibility is still maintained with fibrillary contractions in the muscles. The skin and tendon reflex are lowered, bladder and bowel are intact, and if long continued it may become chronic, or stationary for a time and afterwards recover, the atrophy even disappearing; but, as a rule, they generally succumb from dyspnoea or bulbar phenomena. These cases often run on for years before pneumonia, asphyxia, or some inter-current disease produces death. The prognosis in all cases is bad. The differential diagnosis in poliomyelitis will be found in spinal progressive muscular atrophy, gliosis, polyneuritis, and amyotrophic lateral sclerosis. In spinal progressive atrophy one muscle escapes while another is attacked, but in poliomyelitis the whole group is affected. In the spinal the muscular atrophy is confined to the small muscles of the hand—as a rule, where it commences. In gliosis it differs from poliomyelitis, while the loss of sensibility in the former and the trophic and vaso-motor disturbance remained intact. In polyneuritis we have again the sensibility to guide us and the pain on pressure of the nerve. Against amyotrophic lateral sclerosis are the spastic symptoms, which are not present in poliomyelitis.

It may be mentioned that the aetiology is obscure; no toxin can be blamed, and hereditary taint seems to have no part in the disease. It may occur at all ages and conditions of life.

UNITED STATES OF AMERICA.

Washington, Oct. 12th, 1912.

THE INTERNATIONAL CONGRESS ON HYGIENE AND DEMOGRAPHY.

THE most distinctive feature of the congress was the fact that President Taft took a keen and personal

interest in the proceedings. In opening the first general session Mr. Taft made a remarkably eloquent and practical speech, in which he showed that he fully recognised the supreme importance of public health. He advocated in vigorous language the establishment of a national health department, and further made the eminently reasonable suggestion that the splendid U. S. Public Health and Marine Hospital Service should be so amplified in powers and *personnel* that it might become a national department. Of course, very powerful interests are arrayed against the creation of a national health department, the quack medicine concerns being the most prominent in antagonising any such innovation. These businesses are said to be spending money freely in order to block the scheme and are mainly responsible for the cry which is being raised that a national health department would be no more nor less than a doctors' trust. Naturally, they recognise the significance of the "writing on the wall," for if a national department came into being their potentialities for evil would be greatly curbed.

The congress was so immense and the subjects treated so numerous that it would be impossible within the scope of two or three reports to deal with all the matters referred to. Therefore, the object here will be to consider briefly a few of the most important sections. On the whole, when the situation of the civilised world at the present time is taken into consideration it may be said that

DISEASES OF OCCUPATION

bulk more largely than any other aspect of public health. The world is given over to materialism and industrialism, with the consequences that people are flocking to towns and living generally under conditions that are not conducive to good health or to the upbringing of a strong and vigorous race. There appears to be no means of checking this continuous and progressive movement of the population to crowded centres, for it is as evident and is arousing as much alarm among far-seeing persons in the new as in the old world. Most recent statistics show that the trend of population in the United States and in Canada is to the cities, and this tendency is even more evident in Canada than in the United States. Stress was laid on this phase of the situation in the paper read by prominent public health authorities of Canada at the recent meeting of the Canadian Public Health Association held in Toronto (reported in your columns), and sanitarians of the United States are quite apprehensive of the effects of this herding together in cities, and as eager to devise measures whereby the evil may be successfully grappled with as are their neighbours of the Dominion.

Back to the land would appear to be an excellent solution of the problem, but the difficulty is that the vast majority of city dwellers do not want to go back to the land. Those who were born and brought up in cities are not fitted by physique, habits or tastes for life on the land, while those who have lived on the land, as a rule, find city life more attractive. Until means are thought out of rendering agricultural life more profitable and agreeable it is to be feared that the trend of population will continue in the direction of towns, and the only thing that can be done is to make city life as healthy as possible.

The first steps to be taken to bring about this end are to cause the industrial trades, both in factories and in homes, to be carefully supervised. In the section on diseases of occupation at the congress many papers were read by leading health authorities of the world in which the various aspects of the subject were considered. A very important point in connection with industrial work is the effect upon infant mortality of the employment of mothers in factories. This question is perhaps more serious and acute in Great Britain than in any country, and, therefore, it was in the proper order of things that the best paper was read by an Englishman, Dr. George Reid, D.P.H., Medical Officer of Health for Staffordshire. Dr. Reid whose experience of the conditions of labour in the pottery district warrants him in speaking authorita-

tively, is strongly of the opinion that the employment of mothers in factories has a distinctly injurious effect upon infant mortality. He cites the situation in Staffordshire in support of this argument. In Staffordshire there are large artisan populations, all equally favourably situated as regards domestic circumstances, and not differing in their hygienic surroundings, but presenting a wide difference in the facilities afforded for the employment of women in factories and works. These two groups are the pottery towns, where a large number of married women are so employed, and the towns where the male workers are engaged in ironworks and collieries, while the mothers only engage in domestic work, the trades carried on not affording an opening for the general employment of women. As a fact, the mean infantile mortality in the case of the former group of towns exceeds that of the latter by 28 per cent., the records on which the calculation is made covering a period of thirty years.

An American authority, Mr. Chas. H. Verrill, Bureau of Labour, Department of Commerce and Labour, Washington, D.C., arrived at different conclusions, for, although he found that the high infant mortality at Fall River, Massachusetts, a factory town, where women are largely employed, was due to improper feeding, he also found that the death-rate of infants whose mothers lived at home was almost as high as that of infants whose mothers went out to work. However, the consensus of opinion is that the employment of mothers discourages or renders impossible breast feeding, thus bringing about a high infantile mortality.

A question touched upon in this section and a question which intimately concerns all sorts and conditions of men, in all large cities, was that of unnecessary noise. No one can deny that the noises which go on by day and by night in cities are nerve-racking and harmful, and all will agree that it would be in the best interests of public health if steps were taken to do away with a good deal of such noises. Dr. Clarence John Blake, Professor of Otology, Harvard Medical School, read a paper on the subject, in which he pointed out that the deleterious effect of unnecessary noise was evidenced in the changes occurring in the organ of hearing as the result of continued exposure to loud noise, but also in the fatigue effect showing itself generally and evidenced by various forms of disturbance of function of the nervous system. A great part of the noise incidental to the mechanical operation of modern life, especially in crowded centres, is avoidable. Consequently, Professor Blake argues, the suppression of unnecessary noise is advisable for economic reasons, both in the safeguarding of the human machine and in the saving of wasted mechanical energy, of which the noise is an evidence, a saving of waste in two directions. A society has been formed in America for the suppression of unnecessary noise. There is need for one perhaps in England.

Prof. Dr. L. v. Frankl-Hochwart, K.K. Universität, Vienna, read a paper on the occupation neuroses, by which is meant a disturbance of the muscular innervation, which only sets in after complicated activity of the muscles acquired by practice while the muscles in every other action obey the will. As ætiological factors, one must consider the nervous heredity, the neuropathic diathesis, insufficient alimentation, alcoholism and nicotineism. Professional overwork is one of the main factors; depressing conditions of life and the effects of fright are also predisposing factors. The symptomatology is best observed in the most frequent and most important neurosis—in writers' cramp. One must differentiate between four points—(1) the spastic, (2) the paralytic, (3) the tremor-like, and (4) the neuralgic. Prognosis is not absolutely bad, but always doubtful.

Several papers were read on caisson disease, and all the authors seemed to be agreed that slow decomposition, with a rapidity accelerated in the beginning, as proposed by Haldane, is preferable to a uniform decrease of pressure as a prophylactic measure.

Sir Thomas Oliver, University of Durham College of Medicine, Newcastle, gave an address on the even-

ing of September 23rd, on "Dust and Fume: Foes of Industrial Life." Commencing his address with a practical illustration of the effect of dust by declaring that since the advent of the motor car and macadam roads in England, the foliage was disappearing from trees bordering on highways, the bullfinches and other song birds had been killed, and even the fish had forsaken streams which ran near such highways, Sir Thomas took up the subject of coal mines and dust explosions. He told of experiments made by him, which he said had convinced him that explosions in coal mines are largely due to coal dust. Explosion of coal dust is due to its absorption of oxygen, and Sir Thomas stated that he and his colleagues had treated some of the dust with a chemical fluid, and found that thus treated it was practically non-absorbent.

On the evening of September 24th, Dr. Jacques Bertillon, Chief of the Bureau of Municipal Statistics, Paris, gave an address on the mortality and causes of death by professions. The fact was very clearly brought out in papers read that the United States is far behind Europe in so far as legislative protection of the workman is concerned. Indeed, in only one State—that of Massachusetts—are there really adequate laws in this direction. With regard to home work there is also much room for improvement in the United States, and especially in New York. No city of the world is so overcrowded as is New York, and home work is largely and frequently carried on under conditions of overcrowding and insanitation most injuriously prejudicial to good health.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

EDINBURGH UNIVERSITY GENERAL COUNCIL.

At the statutory half-yearly meeting of the council held on the 26th October, a strong protest was made against the action of the Treasury in attempting to compel the Scottish universities to institute an inclusive fee. On the motion of Mr. J. B. Clark, the minute of the Conference of the Councils of the Scottish Universities (referred to in this column a fortnight ago) was transmitted to the university court, and then Principal Laurie moved, "That the General Council of the University of Edinburgh is of opinion that, in seeking to impose the institution of an inclusive fee as a condition of the payment of Parliamentary grants, the Treasury is interfering unwarrantably with the freedom of the Scottish universities, and that the Business Committee be authorised to take such steps as they may deem advisable in respect of this matter." The motion was a protest, not against the principle of an inclusive fee, but against the Treasury forcing it on the universities whether they wished it or not. Freedom from State control was as important as freedom of the churches. St. Andrews had accepted an inclusive fee for medicine which might be far too small for Edinburgh, and by doing that they were forcing the hands of the other universities, as the inclusive fee was to be uniform. The situation was most unfair to Edinburgh, and had arisen because the universities did not take a stand on sound constitutional principles. Mr. J. Miller Thomson seconded. Principal Morgan pointed out that there were other reasons, apart from the inclusive fee, for protesting against the Treasury's interference, and thought that further experience of the inclusive fee was necessary before fixing the fee for medicine and applied science. Ultimately Principal Laurie's motion, slightly amended, became the unanimous finding of the meeting. At the same meeting the draft ordinance for the founding of a chair of Bacteriology under the provisions of the will of the late Mr. Robert Irvine, who bequeathed £30,000 for the purpose, was approved. The free income of £25,000 will be paid to the professor as salary, and the free income of £5,000 will be applied towards equipment.

OPHTHALMIA NEONATORUM.

A circular by Dr. Thomas F. Dewar on the incidence of ophthalmia neonatorum in Scotland has been issued by the Local Government Board. The disease, if not treated promptly, causes blindness, and accordingly it is satisfactory that the local authorities can require notification of cases to the medical officer of health under the provisions of the Infectious Diseases (Notification) Act. So far, only a few Scottish authorities have adopted this course, although in England many have done so. Where the notification of Births Act has been adopted a notice warning parents of the dangerous character of the disease is sent to parents by post, or through the health visitor. The local authority of Glasgow has made the disease notifiable for a period of three years from August, 1911. In a preliminary investigation Dr. Chalmers learned that about 200 cases occurred annually, and found that while some cases required institutional treatment, in most cases outdoor treatment was sufficient. He advised the local authority to appoint two nurses to do the work that would arise in connection with the notification. From Dr. Dewar's inquiries in twenty of the largest towns in Scotland, it would seem that ophthalmia neonatorum is diminishing in frequency, and that cases of the disease resulting in blindness are much less numerous than they were twenty or thirty years ago. In Edinburgh the incidence of the disease is low, because only a small proportion of the confinements in the city are attended by midwives.

THE INCREASED REMUNERATION UNDER THE INSURANCE ACT.

So far as can be gathered from inquiries among medical men in Edinburgh the general feeling is, that although the concessions made by the Chancellor were as much as, if not more than, was expected, they do not very materially alter the situation. The new offer must be read along with the other conditions of service, which are in many respects eminently unsatisfactory. Doubt is freely expressed as to whether 1s. 6d. can possibly cover the cost of medicine and appliances. Exception is also taken to the allocation of 6d. from the sanatorium benefit for paying the general practitioner for all tuberculosis work. It practically cuts down to a very small figure for work which is difficult, and which ought to be paid by attendance. It is estimated that there will be 1,300,000 insured persons in Scotland. At 9s. this would give a sum of £585,000 for medical benefits of all kinds to insured persons, and on a 7s. basis it would provide a fund of £455,000 for distribution yearly among 2,500 medical practitioners, or £190—£200 for each. It has not yet, however, been estimated how many doctors will actually be required to work the Act. Speaking generally, it is believed that over a very large part of Scotland, with the exception of one or two areas in the South-West, which are not so strong in their opposition, the medical profession will stand to the terms they have demanded, and, while admitting that the concessions made by the Chancellor may afford a basis for reopening negotiations, they will refuse to work the Act even under the new conditions. The suggestion that as a condition of receiving the increased remuneration medical men should be compelled to keep records of their cases is viewed with great distrust, but the vagueness of the statement concerning these reports makes it difficult to express a decided opinion as to the feasibility of the proceeding.

BELFAST.

HOSPITALS STAFFS AND THE INSURANCE ACT

A MEETING of the medical staffs of the Royal Victoria Hospital, the Mater Infirmorum Hospital and the Forster Green Hospital for Consumption, was held in the Medical Institute, Belfast, on Thursday, October 24th, to consider the attitude which should be adopted by the staffs towards some of the questions affecting the hospitals under the Insurance Act. The chair was occupied by Sir William Whitla, M.D., the senior physician to the Royal Victoria Hospital. The special points discussed were those relating to the advice to be given to the hospital authorities as to the admission of tuberculosis patients under the Act,

and as to the payment or otherwise of the medical staffs for attendance on such patients. Sir John Byers urged that in view of probable developments, such as the extension of medical benefits to Ireland, it was premature to come to any decision on these points at present, and this view obtained a good deal of support. On the subject of payment, the general feeling was that to accept payment for attendance on these cases would place the members of the staffs in undesirable competition with the general practitioner outside, and might lead to many complications. It was recognised that on this point the position of the staff of a special tuberculosis hospital, perhaps nearly filled with insurance cases, and not a teaching institution, might be different from the position of the general hospitals, but the staff of the Forster Green Hospital decided to throw in their lot with the others in all respects. After prolonged discussion a resolution proposed by Mr. R. J. Johnstone was agreed to. This was to the effect that in view of the present uncertainty and possible changes in the working of the Act in Ireland, the boards of the various hospitals be advised to admit cases of Tuberculosis on such terms as they may arrange with the Insurance Act authorities, subject to two conditions:—that the cases shall be recommended by their own medical attendants, and that they shall be passed by the staff as suitable for hospital treatment; further, that the staffs remain honorary, as at present; and lastly, that these decisions shall remain in force till July 15th, 1913, when they shall be brought up for revision. It was thought by some members that it would be better to set a shorter time limit, lest matters should settle down and precedents be formed from which it might be difficult to escape, but the majority thought that next July would be soon enough to reopen the discussion, and that before then we should hardly know how we stood in relation to the working of the Act. It was only in relation to tuberculosis cases that the working of the hospitals was considered at length, but there is no doubt that the whole working of these and also of the various special hospitals, and also the important question of certificates will have to be discussed later.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE WOUNDED AND SICK IN WAR.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—If I have any qualification to write on the subject dealt with editorially in your current issue, it is due to the fact that I have witnessed war being waged on as big a scale as the conflict now beginning in the Balkans, and have been able to realise the literally appalling character of the misery and suffering it entails, even when great, albeit insufficient, efforts have been made to provide aid for the wounded and sick. With my late friend, Mr. A. T. Norton, whose death we have recently had so deeply to deplore, I was among the first to volunteer for service under the newly founded Red Cross Society in the Franco-German War of 1870. Mr. Norton was then one of the surgeons of St. Mary's Hospital, Paddington. He was appointed head of an ambulance with me as his second and a small staff of student dressers. With us went to help in our organisation Mr., now, Sir J. Furley. In Luxembourg on the frontier we engaged waggons for ourselves and our stores, and set off for the battle-fields around Metz. We made our headquarters at Briey, a few miles from the scene of the biggest battle of the war—Gravelotte—fought on August 18th. On August 14th a big battle had taken place to the east of Metz, and on the 16th a whole day's fighting at Mars-la-Tour, and many big and little skirmishes had been fought throughout all these days. I cannot find my record of the approximate numbers of wounded, but at St. Privat on the afternoon of August 18th (Gravelotte) the Prussian Guard alone lost nearly 11,000 officers and men killed and wounded. There were, at any rate, many thou-

sands of wounded scattered all over the countryside, and these were for the greater part the more serious cases. It is wonderful what wounded men will do in the face of starvation if they possess the power of locomotion, and those that were able to walk, and some that were fit to travel a few miles in waggons, found their way to the railway beyond Metz and were carried to base hospitals in Germany.

It was impossible to bring to the spot an ambulance service equal to such an emergency. The German service was far from adequate; the French, like all their arrangements in this war, was lacking in every essential requirement. The days of antiseptic surgery had not begun. Listerism and the value of carbolic acid as an antiseptic were being recognised in England, but were practically ignored both by the German and French surgeons. The conditions were very similar to those likely to prevail in the Balkans, for although aseptic surgery will be practised on both sides when possible, there has been very little preparation for the immediate antiseptic dressing of the wounded on the battle-fields among any of the combatants. Most of the wounds will be septic. Where the cover of a roof is to be found, the men will be packed on the floors of the peasants' huts without beds (or bed-pans!) or cover against the cold. Hospital gangrene and septicæmia will prevail, and a huge mortality will ensue among cases that might, under more favourable circumstances, have been saved. This is what happened around Metz in 1870, in civilised France; the conditions must be much more difficult in the poverty-stricken and semi-barbarous regions in which the armies are now operating. I should be sorry to depreciate the value of the work in mitigating human anguish which may be achieved by the Red Cross ambulances sent out by neutral Powers; but it must be hardly more than is a drop in the ocean. It is, of course, the duty of nations waging war to provide ample medical service; and that this can be done was proved by the Japanese in their war with Russia. In spite of the conditions which were, at least, as unfavourable as those in the present conflict, the Japanese wounded were all so wonderfully looked after that the mortality was less than had ever before been known. When neutral nations intervene, as in the present case, it, more or less, relieves the defaulting Powers from a burden they ought to sustain, sets free more fighting forces, and tends to prolong the war and extend its operations. On these grounds alone it has been argued, with reason, that neutral ambulances should be forbidden. But these considerations are not likely to weigh with philanthropists, including doctors, whose strongest impulse is to relieve human misery whenever and wherever they can get into relation with it.

I am, Sir, yours truly,

HENRY SEWILL.

The Old Rosery,
Earlwood Common, Surrey.
October 25th.

THE POSITION OF DENTISTRY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—One unexpected result of the failure of the Dentists Act is now showing itself. You will see by the enclosed report, published this week, of the London County Council Education Committee, to what a prodigious extent tooth decay prevails among the school children. The number urgently in need of dental help runs, in some districts, as high as 80 per cent., and does not fall anywhere below 66 per cent. The same proportion is found all over the country. It is quite as bad in my district, which, as you will see by my card enclosed, is a small town of a "residential" character within 50 miles of London. We have started a dental clinic, and know something about the question. If every qualified dentist in the country were to give a share of his time to the work it would be impossible to deal effectually with the mass of disease. I have tried to do my share in our local clinic, but found my health would not stand it; and this must be the case with many like me. Dental work

does not put a strain on the nervous system quite as severe in some respects as that borne by the surgeon who is constantly dealing with issues of life and death; but the dentist's task is as a whole hardly less trying, and nowhere more so than in work in the mouths of young children of the class in primary schools. Two or three hours in stopping work of this kind is enough to exhaust the strength of the most robust practitioner, who all the time is besides obliged to inhale the foul breath of the patients. We all of us are earning hard livings competing with the quacks who make no private or public sacrifice for their patients, and we cannot be expected to do the work asked of us at the cost of health, strength and income. If the profession had, from the passing of the Dentists Act, been properly protected, there might by this time have been drawn into dentistry an adequate supply of qualified men, and among the juniors enough might have been found to carry on the work of school clinics all over the country. It would be, perhaps, amusing, if not valuable, to hear from "An Interested Observer," whether his clients, the "ethical," *albeit*, unqualified practitioners, whom he defends, are competent and willing to take a share in this work. How many of them are capable of making a correct diagnosis of the simple but varying conditions of disease presented in young children's teeth; how many of them can distinguish between sensitive dentine, for example, and exposed pulp; and how many of them are capable of performing the delicate operations called for in saving teeth of the second dentition so often carious between the ages of 6 and 12? He will find that many of his friends cannot distinguish temporary from permanent teeth at the ages named; he will find that they have no knowledge of necessary science, he will find that they have had no clinical instruction or experience with respect to children's teeth; he will find that they are mostly "out to make money" in the easiest way, that is by supplying badly made artificial teeth without, as other correspondents have pointed out, any regard for surgical conditions, which any qualified man, not being a rascal, would feel compelled first of all to take in hand.

I am, Sir, yours truly,
COUNTRY DENTIST NO. 3.

October 26th, 1912.

THE MOTOR DANGER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The present condition of the motor traffic is a disgrace to civilisation. Apart from the direct danger, it is impossible to use the King's highways without the nerves being irritated by the shrieks, hoots and whistles of motors, and the eyes, throat and lungs penetrated with microbe-laden dust. People who are ill suffer acutely—there is absolutely no quietness obtainable by night or day. If it were not that English people are traditionally law-abiding, the remedy would have been taken into their own hands long ago.

I am, Sir, yours truly,
A SUFFERER.

October 26th, 1912.

OBITUARY.

DR. W. T. COCKING, OF SHEFFIELD.

WE regret to announce the death of Dr. William Tusting Cocking, Emeritus Professor of Materia Medica and Therapeutics in the University of Sheffield, which took place on the 19th inst., at his residence in Ranmoor Crescent, at the age of 50. The deceased, who was educated at Wesley College, Sheffield, and University College, London, qualified as M.R.C.S. Eng., in 1884, becoming M.B. Lond., in 1885, and taking the M.D. (qualifying for gold medal) in 1887. His subsequent appointments included those of house physician, senior obstetric assistant and house surgeon at University College Hospital, and resident clinical assistant at Brompton Consumption Hospital. Dr. Cocking had also a long and honoured connection with Sheffield University. He was a past president

and dean of the medical faculty, and professor of Materia Medica and of Therapeutics for fourteen years, and on resigning his staff appointment a year ago on account of ill-health, the honour was conferred upon him of being elected Emeritus Professor.

Prior to his University appointment the late doctor was associated with the old Sheffield School of Medicine, for a number of years filling the office of honorary secretary. In 1896, when the title of his office was altered to that of "Dean of the Medical Faculty" his colleagues on the council and teaching staff presented him with an address and library desk as tokens of their warm appreciation of his services. His connection with the medical school continued after the amalgamation of that institution with the University College, and was, of course, carried on to the University. He was the representative of the University on the General Medical Council—one of the most distinguished positions to which his professional colleagues could elect him, and he was also hon. secretary of the Sheffield Medico-Chirurgical Society from 1899 to 1905, when he was elected to the presidency of that society. Although his University and Royal Infirmary appointments occupied much of his time, Dr. Cocking had also a considerable private practice in Sheffield till increasing ill-health necessitated a curtailment of his activities. He gave a good deal of attention to the study of miners' nystagmus and his contributions to the medical Press included one on this subject and others dealing with "Case of Myxœdema Treated with Thyroid," and "Case of Ossification of Muscle Associated with Locomotor Ataxy."

Dr. Cocking married Miss Alice Mary Birks, daughter of the late Mr. Edward Birks, of Sheffield, in 1899, and he also leaves a son and daughter.

DEPUTY-SURGEON-GENERAL J. F. CORBYN.

THE death took place, at Cheltenham, on October 24th, of Deputy-Surgeon-General Joseph Frederick Corbyn, aged 82. He was the son of a surgeon-general, and was born in India. After being educated in this country, he graduated in medicine at Edinburgh, and joined the Bengal medical branch of the East India Company's service, in which he remained 28 years. Within four years of his return to India he was attached to the 3rd Sikh Cavalry, and with them went through the Mutiny campaign, taking part in every action in which they were engaged, including the siege and capture of Delhi, the capture of Lucknow, and several other arduous operations. In addition to his medical duties, he was often employed as a combatant officer, and was selected for reconnaissance work on account of his skill in languages. He was wounded more than once, and was several times mentioned in despatches, and thanked by Sir John Lawrence, Governor of the Punjab.

DR. F. M. POPE, OF LEICESTER.

IT is with deep regret that we have to record the death of Dr. Frank Montague Pope, of 4 Prebend Street, Leicester, which took place on October 26th, at the age of 56. The deceased, who was the son of the late Mr. Thomas Pope, of Harewoods, Blethchley, qualified as M.R.C.S. in 1879, becoming M.D. Cantab. in 1901. He was Senior Physician to the Leicester Royal Infirmary for many years, and was Consulting Physician to the Leicester and Rutland Counties Lunatic Asylum and Consulting Medical Officer to the Leicester Institute for Trained Nurses. He was elected F.R.C.P. Lond. in 1902. Dr. Pope served in the South African War and received the medal, and was a Lieutenant-Colonel of the Royal Army Medical Corps, and Chief Surgeon to the St. John Ambulance Brigade. He was an Honorary Associate of the Order of St. John of Jerusalem, a member of the Council of the British Medical Association, the National Association for the Prevention of Consumption, and the Advisory Committee of the Society for the Feeble-Minded. Dr. Pope formerly held appointments at the Royal National Hospital for Consumption, Queen Victoria's Sanatorium, the Great Northern Hospital, and the Royal Hospital for

Diseases of the Chest, City Road, London. The medical profession in Leicester, and the staff of the Royal Infirmary in particular, have sustained the loss of one of their most distinguished members, whose place it will indeed be hard to fill.

SPECIAL REPORTS.

THE HEALTH OF DUBLIN.

THE annual report on the health of Dublin for the year 1911, by Sir Charles Cameron, Medical Superintendent Officer of Health, is a portly volume of 280 pages. It is a matter of some difficulty to pick out of this mass of material what is really pertinent. Since the issue of the last report, the Medical Officer of Health has had, for the first time, the assistance of a medical man as full-time assistant. Curiously enough, we find no mention of this important fact in the report, nor does the assistant's name appear on any of the pages occupied by the names of the members of the staff of the Department of Public Health.

Dublin, as usual, shows a high birth-rate—32 per thousand of the population. It is worth noting that this is nearly double the rate in the suburbs—17 per 1,000. It would seem that in Dublin, as elsewhere, the lowered birth-rate chiefly affects the middle classes.

As usual, also, there is a high death-rate—23 per 1,000 of the population. This is 1.8 above the rate of the previous year, which showed the lowest rate on record. It is, moreover, nearly 50 per cent. higher than the death-rate (15.5) in 77 of the largest English towns in 1911. Only one of these English towns shows a rate of 20 or over. This is Liverpool, with 20 per 1,000, Stoke-on-Trent coming next with 19.9. The increased rate in Dublin last year was principally due to an abnormally large number of deaths from epidemic disease. The epidemic death-rate was almost twice the average for the past ten years—3.9 per 1,000 of the population as against 2 per 1,000.

Sir Charles Cameron professes himself unable to offer any explanation why there was a marked increase of infective disease in 1911, and he appears to adopt Sydenham's suggestion that at times the atmosphere assumes "an epidemical constitution." We may suggest a solid basis for this epidemical constitution in Dublin in 1911. The whole year was unusually dry, so that dust blew freely from January to October. The city—streets, laneways, yards, courts—is in the usual filthy condition in which it satisfied the Corporation of Dublin to keep it. Garbage—rotting vegetables, putrid fish, horse droppings, refuse of every sort—lay in the streets, and the yards and courts had their usual complement of rubbish heaps. All conditions were favourable for the production of infective dust, for the breeding of flies, and doubtless for the contamination of milk and other food. We note that Sir Charles Cameron expresses the opinion that no less than 74 cases of enteric fever were due to infected milk.

It will be remembered that last year the Public Health Department inaugurated a so-called campaign against flies! A price was put on the head of each dead fly brought to the offices of the Department. Small boys were armed with flappers as weapons and paper bags to carry their game. We learn that 21 bags were returned, holding in all about 126,000 flies, the cost to the rates being about 5s. 3d. Anything more ridiculous than this child's play, while leaving the breeding grounds intact, one cannot conceive.

The high rate of infective disease in 1911 affected practically all the zymotic diseases.

The deaths from diarrhoeal diseases (643) were more than double the number in 1910 (238), which again was nearly double the number in 1909 (137). The deaths from typhoid (70) were more than double the number (32) in 1910. The number of deaths from diphtheria (86) was the highest on record. A curious error occurs in calculating the death-rate per 10,000 for this disease, the rate being given as 1.58 instead of 2.87. There was in 1911 a bad outbreak of scarlatina.

During the year the City Council, against the advice of the Medical Officer of Health, repealed a by-law forbidding the keeping of pigs within 50 feet of a dwelling. Of the 463 piggeries in the city, containing 4,626 pigs, 365 are within 50 feet of dwellings. We fear that this instance is characteristic of public health work in Dublin.

REVIEWS OF BOOKS.

INFANTILE PARALYSIS. (a)

THIS valuable monograph on the treatment of infantile paralysis has now been rendered accessible to the English-speaking profession by the excellent translation now before us, for which we are greatly indebted to Mr. Alan Todd, of Guy's Hospital. Starting with an account of the history of the disease, the author goes on to describe in picturesque language the symptoms and course as well as the ætiology and bacteriology of the condition. The work, as a whole, is divided into two main sections, the first of which is concerned with *general treatment*, while the second is devoted to the consideration of the *therapeutic measures* to be adopted in the varieties of paralysis met with. Special attention is directed to the general treatment in the acute stage and stage of repair during the first year. Isolation is very rightly insisted on as a precautionary measure. We are also pleased to note that Prof. Vulpius states that it is useless to prolong electrical treatment beyond a year, as this only tends in time to make the patient extremely nervous and excitable. Prevention of deformity is a matter which is too often neglected, and consequently the author refers at some length to the measures for securing this object. In the third or final stage some form of orthopædic apparatus is called for, and a chapter is given up to the consideration of these. In the chapter on the surgery of paralysis, Prof. Vulpius deals very thoroughly with such subjects as muscle transplantation, arthrodesis, tendon shortening and transplantation, as well as nerve transplantation.

In the second, or special, part, various forms of paralysis, according to their locality, are referred to in detail and their treatment carefully entered into. A special feature is the very complete records given by the author of actual cases which have been under his personal care. A very interesting chapter deals with cases of paralysis of extreme severity in which the patients are for the most part confined to bed or to invalid chairs. Even these cases can often be benefited by surgical measures, as several of the case histories given by the author prove beyond a doubt.

Now that attention is being so frequently directed to the subject of infantile paralysis, this volume appears most opportunely, for it supplies us with a highly impressive account of how much may be done for these unfortunate patients, not only in preventing possible deformities, but also relieving such as exist by orthopædic treatment carefully and scientifically carried out. Professor Vulpius is deservedly recognised as an authority of the first rank on orthopædic surgery in Germany, and now that his views and teaching are rendered accessible to his English confrères we feel certain that his work in this direction will be a real stimulus to greater exertions on the part of orthopædic surgeons in this country.

The wealth of illustrations is an additional feature of interest attaching to this volume, which it is a positive delight to study. It appeals to the physician as well as to the surgeon, for the former usually sees these cases in their earlier stages; while it also has an interest for the general practitioner, who, after studying it, will surely consider it his duty to look upon cases of infantile paralysis as by no means so hopeless as they

(a) "The Treatment of Infantile Paralysis." By Oskar Vulpius, M.D., Professor Extraordinary at the University of Heidelberg. Translated by Alan H. Todd, M.B., B.S., B.Sc.Lond., House Surgeon, Guy's Hospital, late Resident Surgical Officer Royal National Orthopædic Hospital. With introduction by J. Jackson Clarke, M.B.Lond., F.R.C.S. Royal Soc. pp. x., 318, with 243 figures in the text. London: Baillière, Tindall and Cox. 1912. Price 10s. 6d. net.

were once considered to be. We are certainly under a debt of gratitude to the translator and his publishers for the care they have bestowed on the production of this delightful monograph in this its English dress. We trust that its perusal will go a long way towards revolutionising our ideas regarding the treatment of infantile paralysis.

CONDUCT AND ITS DISORDERS. (a)

DR. MERCIER never fails to be interesting, whether he is writing a deep philosophical treatise such as the present, or perpetrating a *jeu d'esprit* such as his altogether delightful "Preliminary Report on the Forcible Bathing of Prisoners." It was with keen anticipations of pleasure, therefore, that we took up this volume for perusal, anticipations which have been more than satisfied.

Dr. Mercier is led to study conduct much as Aristotle was led to the study of ethics, as a branch of biology. There has been some controversy as to whether he is really the pioneer he regards himself, but we think most of his critics have criticised him in ignorance of his position. Whether others have studied conduct prior to him is really immaterial. Columbus was not the first European to visit the New World. The important thing is that Dr. Mercier has studied conduct by a new method. He attempts to lay the foundations of a science of conduct, by attacking his subject on a systematic plan, his principle being derived from biology. In other words, he asks the question: Can human conduct be explained by biological principles? This is a question worth discussion, and if we remember that Dr. Mercier is concerned not with morality but with conduct, it may be admitted that he brings strong support for an affirmative answer.

The whole discussion bristles with points of interest, and it required great self-control in Dr. Mercier to follow his scheme straightforwardly, rather than to turn aside to one or other of the many tempting vistas which offered. We must be content to follow in the same path in this review. We content ourselves, therefore, with suggesting to our readers the lines the author has followed, and do not attempt any criticism or discussion either of his observations or his arguments.

Conduct, says Dr. Mercier, is action in pursuit of ends. The inquiry, therefore, may be conveniently divided into two—the study of action, and the study of ends. Dr. Mercier's methods of analysis of actions is by contrast of two more or less opposed forms of activity. Thus action is spontaneous or elicited, abundant or scanty, instinctive or reasoned, and so on. He develops such analysis in its many phases with an ease of argument and a wealth of illustration which are altogether admirable.

This, however, is only clearing the ground, and it is, when he comes to the discussion of ends that Dr. Mercier becomes more generally interesting. And here a new resemblance to Aristotle breaks out. Dr. Mercier's science of conduct bears more than a superficial resemblance to the Aristotelian doctrine of the mean. Given, says Dr. Mercier, that action is directed toward an end, that action may be excessive or defective. He adds, and here he breaks away from his great predecessor, that it may also be perverted or reversed. Here it must be admitted that a weakness appears. We can understand biological stimulus which causes either excess or perversion, and obstacles which may cause deficiency, but the explanation of reversed action on biological grounds is far from easy. Dr. Mercier fails to help us. "I must guard myself," he says (p. 87), "against being supposed to mean in such cases there is necessarily a real reversal of instinct. What happens is, no doubt, that some antagonistic instinct—for many instincts are antagonistic to others—has gained such predominance and exaggeration, as to swamp the instinct that seems to be reversed; and, for practical purposes, to abolish

and supersede it, either for the time being, or permanently." But reversed action is not the same as action swamped or hindered. We require an explanation not of the failure of the action, but of its reversal.

This analysis, however, furnishes the scheme for the science of conduct. Dr. Mercier then discusses in brief the different forms of conduct, according to the end at which each aims, and under each head he suggests the variations from the norm—in excess or defect, perverted or reversed. Whether we agree with his contentions or not, his application of this scheme to the great departments of human activity is highly suggestive. Following him through the various fields of self-conservative and social conduct—morality, custom and fashion, sexual relations, parental conduct, patriotism, and even the fields of recreation and art, we find that, even if we are not satisfied that he has the key, he has at any rate a key which unlocks many doors.

Dr. Mercier's book is one that cannot be neglected by thinkers. Unlike most deep books, it is easy to read, even by those unused to philosophic writing. His lucidity is beyond praise. To medical men, and particularly to those who have to deal with deviations from the normal where conduct is deranged, we commend the book for earnest study. The reader who comes away without a wealth of suggestions for reflection is past caring for.

TRANSACTIONS OF THE ROYAL ACADEMY OF MEDICINE IN IRELAND. (a)

THE Transactions of the Academy of Medicine for 1912 make, as usual, very interesting reading. A great variety of topics are dealt with, and some of the contributions reach a high standard. Mr. Moore records a death following the use of salvarsan. But one is rather doubtful whether his case (one of general paralysis of the insane) was one in which this drug was indicated. Ehrlich objects strongly to its use in this condition. Many of the fatalities recorded could have been prevented if the discoverer's rules had been observed. Some of the speakers favoured ambulatory treatment; but we are of the opinion that with such a powerful drug this is highly dangerous.

Messrs. Haughton and Stevenson contribute interesting papers on "Congenital Hip Disease." They have had very satisfactory results from the Lorenz method, and it marks a decided advance on the older "open" methods. Mr. Stoney reports encouraging results with "dioradin" in a series of fifteen cases of tuberculosis.

Dr. Rowlette's paper on the Insurance Act clears many perplexities on a topical subject. On the whole in favour of the Act, he pointed out the effect it would have on voluntary hospitals and on medical teaching, especially in maternity schools. In this he was seconded by Dr. Jellett, who has done much to draw attention to the effect it will have unless altered on the teaching of students and midwives.

One of the most interesting papers is by Dr. Dawson on the relation of insanity to life in Ireland. He brings out several curious facts—e.g., that insanity tends to be more marked in agricultural counties; its distribution bears little relationship to that of emigration, crime or alcoholism, and none to density of population, death-rate, or drunkenness. In contradistinction to England, drunkenness is more marked in rural districts than in towns. This paper will bear careful perusal.

The Rotunda Hospital reports, as usual, show general progress and contain two items of special interest. The use of vaccines in puerperal sepsis has now had a sufficiently long trial to enable a definite opinion of their value to be formed. Dr. Rowlette's work has led to their routine use in all septic cases. Hospital stock vaccines, and autogenous ones if these fail, are used in preference to the commercial stock ones. Small doses are employed at short intervals,

(a) "Conduct and Its Disorders Biologically Considered." By Charles Arthur Mercier, M.D., F.R.C.P., F.R.C.S., Physician for Mental Diseases to Charing Cross Hospital. Pp. XXIII. and 377. London: Macmillan and Co. 1911. Price 10s. net.

(a) "Transactions of the Royal Academy of Medicine in Ireland." Vol. XXX. Edited by J. Alfred Scott, M.A., M.D., F.R.C.S.I., General Secretary. Pp. xl. and 521. Dublin: John Falconer. 1912.

and the results prove the value of this dosage. This paper is likely to be widely quoted, and treatment along these lines seems to be opening out in a promising fashion. The Master of the Rotunda Hospital has recorded the first case in Ireland of removal of a thrombosed ovarian vein in a case of pyæmia. As the mortality of cases left without operation is 60 per cent., as against 15 per cent. of those operated on, there is every justification for this procedure. The difficult point is to know when to interfere—should one be guided by the number of rigors or wait till a palpable mass forms?

Dr. Tweedy introduced a very instructive discussion on the operative treatment of uterine prolapse. Each operator seems to favour his own methods. The operation first described by Dr. Jellett of shortening the utero-sacral ligaments marks a real advance in treatment. The ideal method would seem to lie in thorough repair of the perineum coupled with suspension of the uterus to the abdominal wall and tightening the utero-sacral ligaments by Dr. Jellett's method. But each case needs individual treatment; the final word has not yet been said regarding this subject.

THE NURSES' COMPLETE MEDICAL DICTIONARY. (a)

It is a difficult task to compile a book containing a "complete vocabulary of terms which a nurse is likely to meet in her daily work," and at the same time to bring it within reasonable pocket compass both as regards size and price. This has been attempted with some degree of success by the author of this little dictionary, which no doubt will find a niche in many a nurse's library, though some of the words, including such as "ice," "wrist," "yawning," "bath," etc., scarcely appear to need any definition; whilst others—viz., "ponogene," "loinology," "elinquation," and "helcoma," can hardly be called terms that a nurse or anyone else is likely to meet in her daily work. A list of the usual abbreviations used in medicine adds to the usefulness of the book, also the tables of weights and measures for handy reference.

NEW BOOKS AND NEW EDITIONS.

The following have been received for review since the publication of our last monthly list:—

- ALLEN, GEORGE, AND CO., LTD. (London).
The Sheep and Its Cousins. By R. Lydekker, F.R.S. With 61 illustrations. Price 10s. 6d.
The Elements of Child Protection. By Sigmund Engel, translated by Dr. Eden Paul. Pp. 276. Price 15s.
- APPLETON, D., AND CO. (New York and London).
The Principles and Practice of Medicine. By Sir Wm. Osler, Bart., M.D., F.R.S. Eighth Edition. With the assistance of Thomas McCrae, M.D., F.R.C.P. Pp. 1,225. Price 21s.
- BAILLIÈRE, TINDALL, AND COX (London).
Handbook of Diseases of the Ear. Fourth Edition. By Richard Lake, F.R.C.S. Revised and enlarged, with 4 coloured plates and 77 original illustrations. Price 7s. 6d.
The Care and Treatment of European Children in the Tropics. By G. Montagu Harston, M.D.Lond., M.R.C.S.Eng. With Introduction by Sir Patrick Manson, G.C.M.G., M.D., LL.D. Pp. 248, with 17 coloured and plain plates. Price 7s. 6d.
Text-book of Medicine. By G. Dieulafoy, Professor of Clinical Medicine in the University of Paris. Translated from the sixteenth French Edition by Drs. V. E. Collins and J. A. Liebman. 17th thousand in 2 vols., pp. 2,156, with 99 figures and 9 coloured plates. Price 25s.
The Course of Operative Surgery. By Professor Victor Schmielen, with introduction by Professor Bier. Translated and edited by Arthur Turnbull, M.B., B.Sc. Pp. 365, with 435 illustrations, plain and coloured. Price 12s. 6d.
The Nutrition of the Infant. By Ralph Vincent, M.D., M.R.C.P.Lond. Fourth Edition. Pp. 360, with 17 coloured and plain plates. Prices 10s. 6d.
The Prevention of Some Common Diseases in Childhood. By J. Sim Wallace, D.Sc., M.D., L.D.S. Pp. 112. Price 3s. 6d.
Practical Chemistry, including Volumetric Analysis and Toxicology. By Professor A. E. Richards, F.I.C., Second Edition. Pp. 150. Price 3s.
Aids to the Diagnosis and Treatment of Diseases of Children. By John McCaw, M.D., R.U.I. Fourth Edition. Pp. 445. Price 4s.
- BAILE, JOHN, SONS, AND DANIELSSON, LTD. (London).
Surgery for Dental Students and Junior Medical Students. By A. S. Underwood and B. Underwood, M.B., B.S. Pp. 244. Price 3s. 6d.

(a) "The Nurses' Complete Medical Dictionary." Compiled by M. Theresa Bryan, Samaritan Hospital for Women, London. Pp. 206. London: Baillière, Tindall and Cox. 1912. Price 2s. net.

- Studies in Clinical Medicine. By C. D. Hawthorne, M.D., F.F.P. and S.Glas. Pp. 240. Price 6s.
- Tropical Medicine and Hygiene. By C. W. Daniels, M.B.Cantab., M.R.C.P.Lond. In Three Parts. Part III. Diseases due to Bacteria. Pp. 250. Price 7s. 6d.
- CHURCHILL, J. AND A. (London).
Alcoholism: Its Clinical Aspects and Treatment. By Francis Hare, M.D. Pp. 276. Price 5s.
- CONSTABLE AND CO., LTD. (London).
Decisions of the Law Courts under the Medical Act, 1858, and the Dentists Act, 1878. Collected and arranged by C. J. S. Harper. Pp. 377. Price 10s. 6d.
- CORNISH BROS. (Birmingham).
Coprostasis: Its Causes, Prevention and Treatment. By Sir Jas. Sawyer, M.D., F.R.C.P. Pp. 74. Price 2s. 6d.
- FISHER UNWIN, T. (London).
Hypnotism and Disease. By Hugh C. Miller, M.A., M.D. With Introduction by B. C. Lloyd Tuckey, M.D. Pp. 252. Price 5s.
- GALE AND POLDEN, LTD. (London).
Guide to Promotion for Non-Commissioned Officers and Men, R.A.M.C. Compiled by Capt. S. T. Beggs, M.D. Pp. 434. Price 3s. 6d.
- HARRISON AND SONS (London).
An Operating Theatre in Private Practice. By C. H. Whiteford, M.R.C.S., L.R.C.P. Pp. 76.
- HEWITT, WILLIAM G. (Brooklyn).
St. Luke's Hospital: Medical and Surgical Reports. Vol. III. Pp. 554. Illustrated.
- KING, P. S., AND SON (Westminster).
Hygiene for Health Visitors, School Nurses, etc. By C. W. Hutt, M.A.Cantab., D.P.H. Pp. 452. Price 7s. 6d.
Medical Benefit: A Study. By J. G. Gibbon, B.A., D.Sc. Pp. 296. Price 6s.
- Causes Leading to Educational Deafness in Children. Reprinted from *The Lancet* by Macleod Yearsley, F.R.C.S.
- LEWIS, H. K. (London).
Massage and the Original Swedish Movements. By K. W. Ostrom. Seventh Edition. Pp. 216. Price 3s. 6d.
Materia Medica and Pharmacy. By Reginald R. Bennett, B.Sc., F.I.C. Second Edition. Pp. 246. Price 4s. 6d.
- LIPPINCOTT, J. B., CO. (Philadelphia and London).
The Pituitary Body and its Disorders. By Harvey Cushing, M.D. Pp. 342, with 319 illustrations. Price 18s.
- LIVINGSTONE, E. AND S. (Edinburgh).
Extraction of Teeth. By J. H. Gibbs, F.R.C.S., L.D.S.Ed. Pp. 163. Price 7s. 6d.
Malingering and Its Detection. By A. McKendrick, F.R.C.S.Ed. Pp. 94. Price 1s. 6d.
- LONGMANS, GREEN AND CO. (London).
Manual of Surgical Treatment. By Sir W. Watson Cheyne, Bart., C.B., F.R.C.S., F.R.S., and F. F. Burghard, M.S., F.R.C.S. New edition in 5 vols entirely rewritten by T. P. Legg, F.R.C.S., and Arthur Edmunds, F.R.C.S. Vol. III. Pp. 604, with 271 illustrations. Price 21s.
Oxidations and Reductions in the Animal Body. By H. D. Dakin, D.Sc., F.I.C. Pp. 142. Price 4s.
- The Prognosis and Treatment of Diseases of the Heart. By R. O. Moon, M.D.Oxon., F.R.C.P.Lond. Pp. 120. Price 3s. 6d.
- The National University of Ireland Calendar for 1912. Pp. 428.
- Experimental Physiology. By E. A. Schäfer, F.R.S. With 85 illustrations. Price 4s. 6d.
- MACLEHOSE, J., AND SONS (Glasgow).
Life of Sir Wm. Tennant Gairdner. By Geo. Alex. Gibson, M.D., LL.D. Pp. 816. Price 10s. 6d.
- MACMILLAN AND CO., LTD. (London).
Diseases of the Liver, Gall-Bladder and Bile-Ducts. By Humphry D. Rolleston, M.D.Cantab., F.R.C.P.Lond. With plain and coloured illustrations. Pp. 812. Price 25s.
Anæsthetics and their Administration. By Sir Frederick W. Hewitt, M.V.O., M.D. Fourth Edition. With the assistance of Henry Rolinson, M.D.Cantab. Illustrated. Pp. 676. Price 15s.
- MILNER AND CO. (Halifax).
Dactylography, or Study of Finger Prints. By Hy. Faulds, L.R.F.P. and S. Illustrated. Price 1s.
- REDMAN, LTD. (London).
Pathology and Treatment of Diseases of Women. By Professor A. Martin and Professor Ph. Jung. Translated by Hy. Schmitz, M.D. Pp. 476. Price 21s.
X-Ray Treatment of Skin Diseases. By Dr. F. Schultz, translated by Jas. Burnet, M.D., M.R.C.P.Ed. With 130 illustrations. Price 12s. 6d.
Guide to Midwifery. By D. B. Hart, M.D., F.R.C.P.Ed. With 4 coloured and 268 plain illustrations. Price 25s.
Manual of Clinical Chemistry, Microscopy, and Bacteriology. By Drs. Klopstock and Kovarsky, translated by the Rebman Company. Illustrated. Price 12s. 6d.
- SWIFT, STEPHEN AND CO., LTD. (London).
The Doctor and His Work. By Chas. J. Whitby, M.D.Cantab. Pp. 235. Price 3s. 6d.
- WRIGHT, JOHN, AND SONS, LTD. (Bristol).
Heridity, Education, and Vitalism. By Ronald C. Macfie, M.D., C.M. Pp. 302. Price 6s.
Diseases of the Throat, Nose and Ear. By W. G. Porter, M.B., F.R.C.S.Ed. Pp. 276, with 77 illustrations, plain and in colours. Price 7s. 6d.

MEDICAL NEWS IN BRIEF.

The Memorial to Lord Lister.

A REPRESENTATIVE meeting was held last week at the Mansion House, under the presidency of the Lord Mayor, in support of the scheme for raising a fund to establish a memorial to Lord Lister. Among those present were Mr. G. W. Spencer-Lyttelton, representing Prince Alexander of Teck; Lord Cromer, the Dean of Westminster, Sir Thomas Barlow, Sir Francis Champneys, Professor Howard Marsh (Master of Downing College, representing the Vice-Chancellor of Cambridge University), Sir William Osler (Oxford University), Sir J. Wolfe Barry, Lord Kinnaid, the Dean of St. Paul's, Mrs. Garrett Anderson, M.D., Sir J. Bland-Sutton, Sir Victor Horsley, the Hon. W. F. D. Smith, Mr. Boyton, M.P., Mr. F. Morris Fry, Sir W. Watson Cheyne, Hon. Treasurer, and Sir J. Rose Bradford, Hon. Secretary.

The following resolution, moved by the Lord Chancellor, was adopted:—"That this meeting is of opinion that the priceless services of the late Lord Lister to the cause of science and the alleviation of human suffering should be commemorated by a suitable memorial."

The second resolution, moved by Lord Avebury, was also carried unanimously:—"That this meeting cordially supports the scheme which has been adopted by the general committee appointed for the purpose of deciding what should be the form of the memorial—namely, a memorial in Westminster Abbey, to take the form of a tablet with medallion and inscription; the erection of a monument in a public place in London; the establishment of an international Lister Memorial Fund for the advancement of surgery, from which either grants in aid of researches bearing on surgery or awards in recognition of distinguished contributions to surgical science should be made, irrespective of nationality.

Charing Cross Hospital—The Huxley Lecture.

THE Huxley Lecture on "Recent Advances in Science in Relation to Practical Medicine" will be delivered in the Out-patients' Hall of the Hospital on Thursday, the 31st inst, at 3.30 p.m., by Prof. Simon Flexner, M.D., Director of the Rockefeller Institute, New York, with Sir William Osler in the chair.

At 2.30 p.m. on the same day, preceding the lecture, the series of new Laboratories of Public Health and Bacteriology recently formed by the School will be formally opened and handed over to the University of London King's College as their University Laboratories in Public Health and Bacteriology.

"Master's Day" at the Society of Apothecaries.

ACCORDING to ancient custom, the Society of Apothecaries of London kept "Master's Day" by attending Divine service last week at their quaintly-named parish church of St. Andrew-by-the-Wardrobe. A striking sermon on St. Luke, "the beloved physician," was preached by the new clerical Master of the Mercers' Company—the Rev. Stuart Palmer, who is a medical graduate of Edinburgh University. The new Master of the Company is Dr. Bramley Taylor, who succeeds Sir Thomas Crosby, Lord Mayor of London.

Writers' Cramp as Industrial Disease.

THE Home Secretary has requested the Departmental Committee which has been appointed to consider the question of the extension of the Workmen's Compensation Act, 1906, to certain industrial diseases, to consider and report to him on the further question whether writers' cramp should be included under the Act.

Any communication on the subject of the inquiry should be addressed to the Secretary to the Committee at the Home Office.

University of Bristol—Honorary Degrees.

AT the installation of Lord Haldane as Chancellor of the University of Bristol, on the 17th inst., when honorary degrees were conferred on, among others,

the Prime Minister, the Rt. Hon. A. J. Balfour and Lord Roberts, the following honorary degrees were also conferred on local medical men:—The degree of M.D.S. on Mr. W. R. Ackland; the degree of M.Ch. on Mr. Nelson C. Dobson, F.R.C.S., and Mr. J. Paul Bush, C.M.G.; the degree of M.D. on Dr. R. Shingleton Smith, M.D., F.R.C.P., and Mr. Geo. Munro Smith; the degree of LL.D. on Prof. J. Michell Clarke, F.R.C.P., pro Vice-Chancellor of the University, Mr. F. Richardson Cross, F.R.C.S., and Dr. D. S. Davies, M.D., Medical Officer of Health for Bristol.

Medical Sickness and Accident Society.

AT the usual monthly meeting of the Executive Committee of this Society there were present Dr. F. J. Allan (in the chair), Drs. St. C. B. Shadwell, J. Pickett, F. C. Martley, Major Greenwood, Knowsley Sibley, G. N. Caley, Frederick S. Palmer, Mr. F. S. Edwards, H. P. Symonds, and Dr. J. B. Ball. The accounts presented showed that there was a diminution in the number of claims for the month of September, and although the amount paid away was heavy it was under the expectation. The audited accounts and balance sheet for the half-year ending June 30th were presented, and it was gratifying to note that the prosperity of the Society is still increasing in a marked degree. The funds of the Society now amount to over a quarter of a million, and provide ample security for the satisfaction of any claims that may be made. That large funds are required is evidenced by the fact that over £15,000 was paid in sickness benefit last year, and that this sum is likely to be exceeded during the current year. The work being carried on under a system of mutual self help, each member doing his best to promote the interests of the Society, has combined to make it one of the most successful societies of its kind in existence.

Society for Relief of Widows and Orphans of Medical Men.

AT the recent quarterly Court of the Directors of the above Society, the Rt. Hon. Sir Thomas Boor Crosby, Lord Mayor, President of the Society, in the chair, three gentlemen were elected members of the Society. The sum of £514 was voted to be distributed at Christmas among the annuitants of the Charity, each widow to receive £10, each orphan £3, and each orphan on the Copeland Fund £10. This is in addition to the half-yearly grants made in January and July.

The Society only grants relief to the widows and orphans of its deceased members, and the Secretary is constantly receiving letters from widows of medical men asking for assistance, but this has to be refused, as their husbands had not joined the Society. Membership is open to any registered medical practitioner who at the time of his election is resident within a twenty-mile radius of Charing Cross. The annual subscription is two guineas, and there are special terms for life membership. The invested funds of the Society now amount to £101,600.

Further particulars and application forms for membership may be obtained from the Secretary at the offices of the Society, 11 Chandos Street, Cavendish Square, London, W.

University of Oxford.

AT a Congregation held on October 24th, the following degrees were conferred:—D.M., A. R. Wilson, Wadham; B.M., J. L. Birley, University.

A TABLET is shortly to be placed upon the wall of the Edinburgh Hospital for Women and Children to perpetuate the memory and career of Dr. Sophia Jex-Blake, M.D., founder of the hospital, "to whose large courage, insight, and constancy the admission of women to the profession in this country is mainly due."

DR. REGINALD EDWARD THOMPSON, M.D., F.R.C.P., a director of the University Life Assurance Society and for some years consulting physician to the Brompton Hospital for Consumption, who died on September 10, aged 78, left estate of the gross value of £7,195, of which the net personalty has been sworn at £7,058.

SUMMARY OF RECENT MEDICAL LITERATURE ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

Vaccines in the Treatment of Puerperal Sepsis.—Rowlette (*Journ. Obs. and Gyn. Brit. Emp.*, xxi., 6) records a series of cases treated by vaccines in the Rotunda Hospital. Fifty-four patients were inoculated, a bacteriological diagnosis being made in 39 by the method of Döderlein. In five cases autogenous vaccines were used, and these were subsequently employed as stock vaccines. At first $2\frac{1}{2}$ million cocci in streptococcal cases were given as the initial dose, but this was later increased to 5 million and never gave any bad results. In staphylococcal infections the initial dose was 20-25 million and occasionally as high as 50 million. Thirty-one cases of streptococcal infection were treated and in no case did any harm result from the inoculation. For the present the author draws the following conclusions: Vaccines given in small doses do no harm in puerperal sepsis; in the great majority of cases they do good; in many cases they produce immediate and remarkable improvement; autogenous are more trustworthy than stock vaccines, and sometimes succeed rapidly where the latter fail; anti-streptococcus serum, given simultaneously, increases the effect of vaccine; to get the best results accurate bacteriological diagnosis is necessary. F.

Retention of the Fœtus by an Internal Contraction Ring Treated by Continuous Weight Traction.—Willet (*Journ. Obs. and Gyn. Brit. Emp.*, xxi., 6) records a case of a multipara with 10 children all delivered naturally. Labour continued slight for 28 hours before the os was fully dilated, the membranes having ruptured early. The pulse rate having then begun to rise and reached 132 per minute, it was deemed advisable to empty the uterus. The head was easily brought down to the outlet, but there was great difficulty in delivering over the perinæum. When this was effected, it was found that the shoulders were firmly retained in the uterus by a thick ring, which encircled the neck. The child was dead, but there was too great danger to attempt embryotomy. The head was, accordingly, perforated and a cranioclast applied; to the handles of this an 8-pound weight was attached and hung over the end of the bed. Half a grain of morphia was given and the patient slept for three hours, after which a few pains expelled the fœtus, which weighed 6 lbs. 14 ozs.

Two other cases of obstruction of labour are recorded in the same journal by Williamson and Shannon. One was delivered by prolonged traction with forceps, the other by version, the former resulting in a rupture of the uterus and vagina. The latter was effected with considerable difficulty and danger to the patient. In both cases the fœtus was grasped by the neck. F.

Findings at Secondary Operations.—Polak (*Amer. Journ. Obs.*, lxxv. 6), reports the findings in 139 women, of whom 42 had been previously operated upon by the author. The cases are grouped as follows: Where bad judgment was shown in the selection of the first operation, where an incomplete operation was done or the diagnosis was incomplete, where conservation had resulted in the conserved organ becoming diseased, where hernia had followed abdominal drainage, where peritoneal toilet had been hasty, where troublesome visceral adhesions had resulted. F.

Abdominal Cæsarean Section.—Petersen (*Surg. Gyn. and Obs.*, xv. 1.) considers (1) the position of Cæsarean section in contracted pelvis with induction of labour as to which is most advantageous to the mother and child in degrees of contraction between 7.5 and 9.5 cm. If there is a choice of method,

induction should not be done under the 36th week.
(2) Under what conditions is craniotomy of the living child indicated in preference to Cæsarean section?
(3) Under what conditions is pubiotomy preferable?
(4) Under what septic conditions is Cæsarean section indicated and when is the operation unjustifiable?
(5) What type of the operation is to be selected in different cases? F.

Pelvic Inflammation in Women.—Lock (*Journ. Obs. and Gyn. Brit. Emp.*, xxii. 1.) studies 118 cases, 100 of which were operated upon. In a large proportion no organism could be found. The commonest course of infection is ascending, but may be descending in tubercular infection and from the intestinal tract. The gonococcus may ascend soon after infection and cause double salpingitis with consequent sterility, which was the general history given by those patients in whom that organism was evidently the cause of disease. It may remain latent in the cervix and only ascend to the tubes after a pregnancy has occurred. A history of sterility with recurrent attacks of pain and discharge is practically diagnostic of gonorrhœal infection. Hydrosalpinx was either double or associated with salpingitis of the opposite side and the symptoms dated back to the last puerperium. In none did the history suggest gonorrhœa. In nearly half the cases of pyosalpinx the condition was double, and in all cases the opposite tube was inflamed. Of 12 with a definite history of gonorrhœa nine were sterile. In the cases of pelvic inflammation all that were operated upon had been confined within 10 weeks except one, with an interval of seven months, and in all the cases in which the pus was examined the streptococcus was isolated. In five cases there were abscesses in the uterine wall. F.

Rodent Ulcer Following Psoriasis.—Gray (*Brit. Journ. of Dermatology*, September, 1912) gives the history of a lady, æt. 56, who had suffered from psoriasis for thirty-two years, and in spite of various forms of treatment had never been completely cured. Although the patient had taken considerable quantities of arsenic, there was no sign of arsenical keratosis. Three years ago a small ulcer formed in the gluteal cleft, and gradually increased in size in spite of treatment with X-rays and radium. The ulcer was situated in the middle line and extended rather more to the left than to the right. It was attended with considerable pain and some discharge. On the left side the margin of the ulcer was continuous with an old patch of psoriasis, but at the right margin the skin was normal. As a diagnosis of malignant ulceration was made the ulcer was freely excised. On histological examination it proved to be a rodent ulcer. There does not appear to be any previous case of rodent ulcer in this situation recorded, though one has been described in the groin, and Whitfield has recorded one as occurring in a psoriasis patch on the shoulder. In the majority of cases of epithelioma which have been described as occurring in psoriasis patches there has been marked evidence of the so-called arsenical keratosis, but this was quite absent in the cases described by Whitfield and Gray. It is interesting to note that the treatment with X-rays and radium failed entirely to control either the pain or discharge from the ulcer. F.

Diabetes Mellitus and Tuberculosis.—Montgomery (*Amer. Journ. of the Med. Science*), October, 1912) in an interesting paper discusses some of the relations of these two diseases. From the evidence he has collected he has not been able definitely

to prove that tuberculosis occurs more frequently in diabetics than in the general population at the same age periods. He has, however, been impressed by two facts: (1) the lowered opsonic index to the tubercle bacillus and a number of other bacteria in diabetes; and (2) the large number of cases of diabetes that late in the course of the disease develop a very acute, extensive, and rapidly fatal form of pulmonary tuberculosis. Out of 355 autopsies collected from the literature since 1882, including Montgomery's twenty-five cases, 138 or 38.9 per cent. revealed pulmonary tuberculosis, mostly in an acute form. In no single instance was tuberculosis of bones found to be associated with diabetes. As a rule, when the two diseases occur together, the diabetes and not the tuberculosis can be shown to have been the primary trouble. From the number of patients that have improved both as to their tuberculosis and diabetes, one cannot consider the prognosis in the combination of diabetes and tuberculosis as necessarily more hopeless than in either disease alone.

K.

Changes in the Ureter Resulting from Tying It.—Corbett (*Amer. Journ. of the Med. Sciences*, October, 1912) reviews the conclusions of experimental workers on this important problem. At the beginning of his researches he hoped to be able to tell in a single word whether or not it would always be necessary to remove a kidney having an atresia of the ureter from any cause. He soon found, however, that the answer must be ambiguous, for the results of atresia of the ureter do not always seem to be the same. There almost always results severe destruction of the kidney after prolonged obstruction, and to save to any extent the functional capacity of the kidney the obstruction must be removed not later than six to ten days. In cases where the obstruction has lasted more than twenty-four days the removal of the kidney seems justifiable on the following grounds: (1) There remains but little functioning kidney. (2) Hydronephrosis is a common result of atresia of the ureter and its existence is always a potential danger. (3) In some cases there occur changes in the untouched kidney and we are led to assume that these changes result from the presence of the no longer functioning kidney. That infection of the hydronephrotic fluid by low grade bacteria may be the cause of these kidney changes, does not alter the conclusion.

K.

Two Cases of Stabbed Heart Treated by Immediate Suture.—Mossop (*South African Med. Rec.*, July 27, 1912) reports the following:—Case I.—A coloured male, *æt.* 31, was admitted to hospital an hour after being stabbed in the chest. On arrival he was conscious, but in a collapsed condition; very restless; pulse 130. There was an incised wound in the fifth intercostal space, just internal to the nipple line. His clothes were soaked in blood, though none was escaping at the time. It was obvious that serious internal hæmorrhage was taking place. Under light chloroform anaesthesia, the wound was enlarged, the fifth costal cartilage was found divided, and an inch of it and of the sixth were removed. Blood was escaping into the left pleural cavity at each diastole through a slit-like wound in the pericardium. With sutures at the edges of the pericardial wound to act as retractors, this wound was enlarged and great hæmorrhage followed, which made it impossible to find the seat of bleeding. After removing the cartilage of the fourth rib, and introducing the finger it was possible to tilt the heart upwards and to the left, so as to bring the ventricles into view. A wound was then seen in the right ventricle, leaking blood at each diastole. This was closed with three sutures of chromicised catgut, passed on a fine fully curved bowel needle. The passage of the sutures did not seem to incommode the action of the heart, but while they were being tied its action became so tumultuous as to make it difficult to distinguish systole from diastole. The sutures checked hæmorrhage immediately. A fine rubber tube with a gauze wick was anchored to the pericardial opening. Lavage was not

employed, and the clot in the pleural cavity was left to be absorbed. The patient recovered and left hospital in six weeks. Case II. A Spaniard had received seventeen stab wounds, one of which, about an inch long, was situated in the fourth intercostal space, one inch to the left of the sternum. By a similar procedure to that in the last case, the heart was exposed, and a wound in the left ventricle sutured. The patient recovered.

S.

The Venous Origin of Middle Meningeal Hæmorrhage.—Jones (*Med. Review*, September, 1912) holds that the grooves on the cerebral surface of the cranial bones are due not so much to the middle meningeal artery and its branches as to the interdural venous sinuses which course for the most part with the branches of the artery. The artery is but a small constituent of a much wider vascular channel, the bulk of which is composed of meningeal venous sinuses. These are mere clefts in the thickness of the dura mater, lined by endothelium, like the well-recognised intracranial sinuses. The writer showed that it was impossible to cause any extensive separation of the dura mater from the bone without some laceration of the venous sinuses, the artery remaining uninjured. He examined three cases in which death resulted from middle meningeal hæmorrhage, and in each case the only lesion found was in the cranial wall of the venous sinus which accompany the middle meningeal artery. The integrity of even the most minute arterial twigs was striking. In children, a trivial injury, so slight that no symptoms of concussion are evident at the time, may produce fatal meningeal hæmorrhage. He quotes a case from Erichsen where a child ate her dinner after a fall down stairs and was found dead in bed next morning. There was a clot between the dura and the bone on the side on which the head had been struck, but without any fracture. It was not likely that the artery was injured. He points out that the bleeding when opening the skull is more venous than arterial in character. It usually wells up out of the wound, and is easily controlled by pressure. Cases where arterial ligation is necessary are exceptional, and compression of the common carotid artery often has no effect on the hæmorrhage.

S.

Rupture of the Colon from Injection of Compressed Air.—Cotton (*Med. Review*, September, 1912) reports a case in which, as a practical joke, the nozzle of a compressed air tube was brought against (not inserted into) the anus of a boy, *æt.* 16, outside his clothes, and the current turned on. He suffered sudden sharp pain and fainted, and was brought to hospital, where the abdomen was opened two hours after the accident. Before opening the peritoneum, the operation wound was filled with normal saline. When the peritoneum was opened large amounts of air burst and bubbled through this fluid. Over the whole of the colon were multiple sub-peritoneal hæmorrhages. At various points on the sigmoid, descending and transverse colon the peritoneum was torn, and in five places the longitudinal bands were also torn, the torn ends being separated for about three inches, without damage to the deeper muscular layers. The bands and peritoneal tears were sutured. Just above the base of the cæcum was a perforation half an inch in diameter. A right-angled glass tube was sewn into it, and brought out through a small incision near McBurney's point. Two days later bowel contents were draining freely through the tube. The patient recovered. The writer uses extra strong tubes in all cases in which gut of doubtful strength or vitality must otherwise be left under conditions of probably increased internal pressure from gas, due to atony of the gut from any cause. This procedure applies not only to pneumatic, but also typhoid and similar perforations, and to doubtful bits of gut in strangulated hernia, and often does away with the necessity of resection.

S.

DR. ROGER N. GOODMAN, of Kingston, has presented the Queen Elizabeth Grammar School of the borough with a leaving scholarship of £60 a year.

NOTICES TO CORRESPONDENTS, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature* or *Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.
The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.
Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8 Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

DR. L. H. P. (London, W.).—We quite agree with you that some degree of medical censorship might well be established over the advertisements that, in many instances, deface the headings with their glaring inaccuracies. The latest example of how not to do it may be seen in the poster depicting a damel about to titillate the submental region of a particularly placid-looking bovine, beneath which affecting scene appear the words, "— (a well-known meat extract) tickles the *palate*." (The italics are ours.)

MUSEUM OF SAFETY AND HEALTH APPLIANCES.

THE Home Secretary has stated in reply to Mr. Gill that a scheme for a museum of safety and health appliances has been under consideration for some time. It has been decided to erect a special building for the purpose, and a site has been secured in a central position in Westminster. Plans have been prepared after consideration of the arrangements in the most important of the museums of this kind on the Continent, and it is hoped that a beginning will be made with the erection of the building at an early date.

DR. R. S. J.—The drug referred to was tried by several practitioners in cases it was reputed to benefit, but as the results were negative, it went, as a matter of course, out of use, and has not been heard of for some time.

EDINBURGH STUDENT.—You will see that new editions of two of the books on your list are announced in another column. You should have no difficulty in procuring the other, as we understand it is not out of print.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, OCTOBER 30TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5.30 p.m.: Mr. J. F. Colyer.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton, S.W.).—4.30 p.m.: Dr. Mackenzie: Artificial Pneumothorax.

THURSDAY, OCTOBER 31ST.

ROYAL SOCIETY OF MEDICINE (SECTION OF NEUROLOGY) (1 Wimpole Street, W.).—8.30 p.m.: Presidential Address: Dr. H. H. Tooth, C.M.G.: Observations upon the Growth and Survival Periods of Cerebral Tumours, Based upon the Records of 500 Cases, with Special Consideration of the Group of the Gliomata (illustrated by micro-photographs).

CHILD STUDY SOCIETY, LONDON (Royal Sanitary Institute, 50 Buckingham Palace Road, S.W.).—6.15 p.m. to 7.15 p.m.: Mrs. F. F. Andrews: Reception and Short Address. 7.30 p.m.: Dr. F. H. Hayward: Statistical Theory for Teacher and Administrator.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms Titheborno Street, Edgware Road, W.).—8.30 p.m.: Discussion on the Preparation of the Patient, Selection of Anesthetic, and Method in Difficult Types of Persons during Abdominal and Pelvic Operations (opened by Dr. D. Buxton).

FRIDAY, NOVEMBER 1ST.

ROYAL SOCIETY OF MEDICINE (SECTION OF LARYNGOLOGY) (1 Wimpole Street, W.).—4.30 p.m.: Cases and Specimens by the President, Mr. J. F. O'Malley, Mr. F. F. Muecke, Mr. A. R. Tweedie, Dr. James Donelan, Mr. H. J. Davis, and others.

ROYAL SOCIETY OF MEDICINE (SECTION OF ANESTHETICS) (1 Wimpole Street, W.).—8.30 p.m.: Dr. G. A. H. Barton, Dr. J. F. W. Silk, Mr. H. E. G. Boyle and Mr. G. E. Gask.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5 p.m.: Prof. A. Keith.

Appointments.

CROOKSHANK, F. G., M.D., M.R.C.P., Assistant Physician to the Belgrave Hospital for Children.

GRAHAM, G. M., M.B., Ch.B. Edin., Junior Assistant Medical Officer at the Stirling District Asylum, Larbert.

HOWELL, B. WHITURCHUR, M.R.C.S., L.R.C.P., House Physician at the Royal Free Hospital.

O'SULLIVAN, D., M.B., B.Ch., R.U.I., Certifying Surgeon under the Factory and Workshop Acts for the Dingle District of the county of Kerry.

RANSOM, P. W., M.R.C.S., L.R.C.P., House Surgeon at the Royal Free Hospital.

SIMMONDS, B. SANGSTER, M.B., B.S., M.R.C.S., L.R.C.P. Lond., Resident Casualty Officer at the Hampstead General and North-West London Hospital.

Vacancies.

Down County Infirmary.—House Surgeon. Salary £60 per annum, with board and residence. Immediate application to Dr. Tate. (See advt.)

Corporation of London.—Medical Officer of Health. Salary £1,000 per annum. Applications to the Town Clerk on or before November 11th. (See advt.)

Teignmouth Hospital, S. Devon.—House Surgeon. Salary £100 per annum, with board, lodging, and laundry. Applications to the Honorary Secretary.

Tooting Bec Asylum, Tooting, S.W.—Third Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Applications to the Medical Superintendent, Tooting Bec Asylum, Tooting, S.W.

Warwick County Asylum.—Second Assistant Medical Officer. Salary £175 per annum, with board, apartments, and laundry. Applications to Dr. Miller, Hatton, Warwick.

The Middlesex Hospital, W.—Third Assistant. Salary £150 per annum. Applications to F. Clare Melhado, Secretary-Superintendent.

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—Bicester (Oxon), Blyth (Northumberland).

Births.

CAMPBELL.—On Oct. 26th, at 13 Lynedoch Place, Edinburgh, the wife of Basil Patrick Campbell, F.R.C.S. Edin., of a daughter.

DINGLE.—On Oct. 24th, at Sandakau, British North Borneo, the wife of Percival A. Dingle, M.R.C.S. Eng., L.R.C.P. Lond., of a son.

TAYLOR.—On Oct. 23rd, at Tun Bridge, Liphook, Hants, the wife of J. J. Taylor, M.A., M.D. Cantab., of a son.

Marriages.

SHELDON—KENSINGTON.—On Oct. 24th, at the Church of St. John the Baptist, Thayetmyo, Burma, John Henry Sheldon, M.B. Lond., M.B., Ch.B. Vict., Burma Railways, second son of the late J. H. Sheldon, of Manchester, to Eleanor Gladys Kensington, M.B., B.S. Lond., younger daughter of Col. Edgar Kensington, late Royal Artillery.

STEVENS—PATCH.—On Oct. 22nd, at Tunbridge Wells, G. J. B. Stevens, L.R.C.P., M.R.C.S., and L.S.A., to Sarah Jane, youngest daughter of the late William and Jane Patch, formerly of Merriott, Somersetshire.

Deaths.

HAYES.—On Oct. 24th, at Audrey, Bognor, Thomas E. D. Hayes, M.D., in his 74th year.

HENDERSON.—On Oct. 21st, at Lynehurst, Worthing, Alexander Henderson, M.B., C.M. Edin., formerly of 21 Pitt Street, Edinburgh, after a long illness.

HOLLAND.—On Oct. 26th, at Fairview, Amberley, Glos., Edward Wilmot Holland, B.A. Cantab., M.R.C.S., L.R.C.P. Lond., F.Z.S., third son of the late Rev. Edward Holland, M.A., Rector of Camerton, near Bath.

LAKING.—On Oct. 22nd, suddenly, at 18 Cavendish Square, Eleanor Mary, the beloved wife of Sir Francis Laking.

POPE.—On Oct. 26th, at 4 Prebend Street, Leicester, Frank Montague Pope, M.D., F.R.C.P., son of the late Thomas Pope, of Harewoods, Bletchingley, Surrey, in his 57th year.

WOOD.—On Oct. 22nd, at his residence, 53 Grosvenor Street, Chorlton-on-Medlock, Manchester, John William Atkinson Wood, M.R.C.S., L.R.C.P., eldest son of the late John Atkinson Wood, of Manchester.

No. 19.

NOTES AND COMMENTS.

Ireland and Mr. Lloyd George's Proposals. We publish in our correspondence column a letter from Dr. McGrath, of Dublin, with regard to the relation of Ireland to Mr. Lloyd George's recent proposals. The medical profession in Ireland is only indirectly

affected by these offers, as the Insurance Act, as it stands, does not provide medical benefits for Ireland. There are signs, however, that the Irish party may before long demand the provision of medical benefits. There is no doubt that the benefit was excluded from the Act because it was thought that the friendly societies could make easy terms for administering benefits outside the Act. The societies have found, however, that medical men want fair rates, whether their service be given under the Act or outside it, and as a result those politicians who are most closely in touch with the friendly societies are beginning to think that they made a mistake in demanding the omission of the medical benefit for Ireland. However this may be, Dr. McGrath's suggestion is a good one. As soon as the decision of the profession in England on the Chancellor's proposals is known, the profession in Ireland must consider its position toward friendly society work outside the Act. This can best be done at such a meeting as he suggests, and we have no doubt that the matter will shortly be taken up by the Conjoint Committee representing the profession of Ireland.

The Hospitals and the Insurance Act. So much prominence has been given to the position of general practitioners under the Act that the interests of the consultants and specialists have to a great extent been set aside. What is to become of our great hospital system under the National Insurance Act? First of all, there cannot fail to be a considerable reduction in hospital patients. Persons of the insured class are not likely to flock to hospitals in crowds as they now do if they can at any moment command gratis the services of a private medical man. That being the case how is the hospital medical staff to gain its experience? Then, again, the majority of honorary staffs have signed the Association pledge that they will not attend insured persons at hospital except on terms approved by the profession at large. There are a few—very few—members of hospital staffs who have refused to make this promise. Possibly they are looking out for governmental loaves and fishes as a reward for their disloyalty to their brethren. Anyway, in future life, they must look forward to nothing but contempt and ostracism. The practical question now before the consultants and specialists is whether the Government proposes to pay hospital

medical staffs and to endow the general and special hospitals, or is our vast voluntary system to go by the board as part of the cost of Mr. Lloyd George's scheme?

What Manchester Says.

We have received a long letter from the National Medical Union, which represents, primarily at any rate, that important factor, the views of the Manchester men. The main argument appears to be the little real value of the recent capitation fee of 8s. 6d. now offered by Mr. Lloyd George. The first deduction for drugs, instruments and appliances alone is estimated at 3s. 6d. per head, a sum that accords with a German experience extending over 25 years. Working out the rest of the figures the total is brought out by the Union as follows:—

	s.	d.
Drugs and appliances	3	6
Mileage	1	0
Medical benefit of non-residents ...	0	3
Operations	0	6
Consultations	0	3
Administration	0	3
Total deduction	5	9

If this be right there will be little left for ordinary attendance under the Act. The proposed supervision of medical men is dealt with thus:—"The disciplinary clauses of the Regulations are particularly objectionable to the medical profession. A tribunal called the 'Committee of Complaints,' predominantly composed of laymen, is set up, and the findings of this Committee are dealt with by the local Insurance Committees, composed of a still larger majority of laymen. It is to be hoped that every doctor will read and re-read the disciplinary regulations (Nos. 48 to 81 inclusive) and ask himself whether he is prepared, for the sake of settling this dispute, for the sake of preventing the launching of a public medical service, or for any reason at all, or in any circumstances whatever, to submit himself to such a condition of medical services."

Sewage Sludge Disposal. So far as we are aware, a full technical description of Dr. J. Grossmann's process for the disposal of sewage sludge has not yet been published, but if the practical experiment on a big scale, which is to be carried out at Oldham, proves successful he will indeed have done the State some service. We are told that the process deals with the sludge in a hygienic manner, producing automatically within a small area dry manure and completely separating the grease and fatty substances. It is estimated that by this pro-

cess about 1,000,000 tons of manure, at present running to waste, could be produced in this country, and 50,000 tons of phosphates, 50,000 tons of potash salts, and nitrogen equal to 100,000 tons of sulphate of ammonia taken back to the land. These constituents have an intrinsic value of about £2,500,000, and would be available for manuring at least 3,000,000 acres. The Oldham Town Council, representatives of a hard-headed Lancashire community, have proved their belief in Dr. Grossmann's process by providing at great cost the complete plant needed for treatment of the borough sewage. That fact alone inspires us with a confident hope that their confidence will be fully justified.

It would have been very wonderful if, unlike all the legislation of the kind in late years, the **Midwives Act** had not disclosed serious flaws as soon as it was put into full activity. A woman was summoned at Feltham last week for acting as a midwife for gain, she not being certified under the Act. She admitted acting, but said she had only done so in cases of emergency, which she was entitled to do under the Act. A discussion took place regarding the meaning of "emergency." Dr. C. W. F. Young, medical officer for the county, contended that the emergency ended immediately after the birth of the child. It was then the defendant's duty to instruct the husband or some other person that she could not undertake further responsibility unless a doctor were called in. She could, however, remain in attendance as a nurse. The Bench dismissed the summons, holding that the defendant had attended cases only in emergencies, and that after the birth of the child, she had become an ordinary nurse. If this is the correct interpretation of the Act, it will not need much ingenuity on the part of uncertificated women to evade its penalties with impunity, and to deprive poor women of the security the law was devised to provide.

THE official reports for 1911 on **Inoculation against Plague and Cholera** in the Bombay Presidency, and on Cholera in Calcutta, exhibit striking statistics with regard to the efficacy of inoculation in these diseases. During the year the number of persons inoculated against plague was 93,655, as against 30,635 in 1910. Of this total 32,047 were inoculated in the Dharwar district, the worst affected in the Presidency. Eighty-one cases were reported among persons who had been inoculated, of which 38 proved fatal. But among the latter cases 36 were apparently in the incubation stage at the time of inoculation, the disease having been contracted before the serum had time to react. Of the remaining two cases, one developed plague after one month and the other after two months. As showing the relative immunity to plague of inoculated persons the following figures relating to the town of Bijapur, which were checked by the Civil Surgeon, are instructive: Among 2,742 inoculated there occurred 20 attacks with 3 deaths; among 30,258 uninoculated there occurred 1,695 attacks with 1,150 deaths. Similar comparative figures were reported from many towns and villages, the mortality being everywhere unmistakably controlled by inoculation. In one village 75 per cent. of the population of 450 souls were inoculated. About two months later dead rats appeared, showing the presence of plague infection, but no cases of plague occurred. Cholera statistics from Calcutta likewise show striking results. In the

Campbell Hospital 232 cholera cases were treated, a large number of them by Major Rogers' method, and no fewer than 141 recovered. Major Rogers, in charge of the Medical College Hospital, adopted his own treatment. Out of 136 in-patients 96 recovered, a percentage of 70.59.

LEADING ARTICLES.

THE NATIONAL INSURANCE ACT.

THE present situation of the medical profession with regard to the Insurance Act is more or less that of an army drawn up for the final shock of battle, to whom terms of settlement have suddenly been offered by the enemy. At any rate, the proposals of Mr. Lloyd George are now before us and it remains for medical men in all parts of the United Kingdom to decide whether those terms shall or shall not be accepted. Needless to remark, their decision is fraught with issues vital to the welfare not only of insurance doctors, but of all members of the profession. Fortunately, the British Medical Association presents an organisation available for obtaining a referendum from the medical men of the United Kingdom. Summonses have already been issued for early meetings all over the Kingdom, and the whole matter will be carefully discussed, point by point, before the local delegates are charged with the momentous decision to be recorded in the Representative Meeting. Meanwhile, it would be unwise to attempt any forecast of the result of the plebiscite, although it may nevertheless be permissible to offer a few general observations. One of the events of last week was the festival dinner of the Irish Medical Schools' and Graduates' Association, at which two important speeches were made upon the subject, and these will be found reported elsewhere in our present issue. The first was by Sir James Barr, President of the British Medical Association. His bitter hostility to the Act as "a wretched makeshift" was in no wise abated. His main argument was based upon the contention that "the service contemplated by the Act was the worst possible medical service that could be given." He maintained that the Act was framed on a charitable or a semi-charitable basis, inasmuch as it could be administered only by linking up with the charitable institutions, such as the hospitals and dispensaries. That phase of the question, in our opinion, has not been so far adequately grasped either by the profession or by the public. Such a medical service, with which we were threatened, said Sir James Barr, would be enormously costly, and if attempted by the State under present circumstances, would be supported only by the riff-raff of the profession. The other speech, that of Dr. Esmonde, M.P., was of value as it may fairly be assumed that it reflected more or less clearly the average Parliamentary views. His words conveyed a definite impression that the sympathies of the House were with the medical profession. At the same time he hinted that were Mr. Lloyd George's last concessions rejected, the goodwill of

Parliament might thereby be alienated. Dr. Esmonde's views are of special value as he has never hesitated to criticise the proposals of the Chancellor of the Exchequer on non-political grounds. He has had a prolonged experience of the difficulties of general practice, and it is a thousand pities that Mr. Lloyd George's policy was not based in the first instance upon practical guidance from sources of the kind rather than that of medical advice from men whose interest in actual practice is academic or from administrative bodies vitiated by a similar detachment. Dr. Esmonde commented on the possibility that failing agreement an attempt might be made to organise a modified State service in great cities, such as London, Liverpool and Manchester. That is the familiar policy of the thin end of the wedge, a favourite resort of the perplexed politician. Dr. Esmonde was emphatic on one point, namely, that under no conceivable circumstances would medical men submit to place their methods of practice under lay supervision or control. To that view we have no hesitation in according our strong assent, nor in advising medical men, whatever they may think of other proposals, to unite in rejecting any proposition of the kind with short shrift, or, better, with none at all. It is to be hoped devoutly that at the present juncture medical men will be practically unanimous in their decision for or against acceptance. Otherwise the medical profession will be riven asunder from one end to the other, and we may bid adieu for many a long day to the prospect of that abiding unity and organisation which alone can place our interests upon a secure and permanent foundation. In conclusion, we may quote the eloquent words of Sir James Barr:—"I want," he said, "the medical profession to study this matter and to see what is best for them, not merely in pounds, shillings and pence, but in upholding their own honour and dignity. I hope we shall arrive at a right decision. Medical men have been far too charitable in the past, and they are very charitable in the present. There is nothing that appeals to a medical man so much as suffering, and wherever he sees it he tries to relieve it. Whether or not this Act crumbles to the ground, as I hope it will, medical men will always continue to look after the poor, the destitute, and the suffering. The public may rest assured that medical attendance will be as good in the future, if the Bill goes to pieces, as it has been in the past, and that their interests are perfectly safe in our hands. We will work in the interests of the public, though we are not inclined to work very much for the Government."

CURRENT TOPICS.

The Mode of Infection in Poliomyelitis.

SINCE the announcement, in 1909, by Landsteiner and Popper, that poliomyelitis could be experimentally transmitted to monkeys, considerable activity has been shown with regard to the study

of the ætiology of infantile paralysis. The parasite is a highly resistant one, being capable of surviving in dust, especially if enclosed in protein matter, for weeks and months, and in diffuse daylight indefinitely. In his address at Charing Cross Hospital last week, Professor Simon Flexner, Director of the Rockefeller Institute, New York, as Huxley Lecturer, advanced the view that the nasal mucous membrane was the site both of ingress and of egress of the virus in man, which ascended by the olfactory nerves to the brain, multiplied first in and about the olfactory lobes, and in time passed, as he believed, into the cerebrospinal fluid which carried it to all parts of the nervous organs. But the establishment of the respiratory avenue of entrance of the virus did not exclude all other modes of possible infection, and the preponderance of cases of poliomyelitis in the late summer and autumn months early suggested an insect carrier of the infection. House flies could act as passive contaminators, since the virus survived upon their body and within their gullet. So far it had not proved possible to infect the common varieties of mosquito, but in one instance infection had been produced in bed bugs which were made to feed on the blood of inoculated monkeys. The virus remained alive within these insects for many days, and the inoculation of monkeys with a filtrate prepared from them gave rise to characteristic paralysis and anatomical lesions. The result was significant, since it showed that insects were capable of taking up the virus from the blood where it existed in minimal quantities and of harbouring it for a considerable period in an active state; but it did not show that multiplication occurred within them or that in Nature they acted as the agents of inoculation. The employment of the immune serum, taken from monkeys or from human beings, exercised a definite, if not very strong, protective action on inoculated monkeys, but none of the sera could be regarded as having more than touched the fringe of the problem of a cure for the disease. As to the use of drugs, when the inoculation of virus and the administration of urotropin were begun together and the administration continued for some days afterwards, the development of the paralysis was sometimes, but not always, averted.

Laboratory Developments at Charing Cross Hospital.

THE formal transference of the newly-provided laboratories for students of bacteriology and public health from the medical school of Charing Cross Hospital to the University of London took place last week. Now that the preliminary teaching formerly undertaken at Charing Cross has been transferred to King's College, the laboratories at Chandos Street have thus been set free, as it were, for the purpose of more advanced studies. These have now been altered and refitted to meet the needs, not only of systematic class-teaching for the Diploma of Public Health, but also of research and investigation work. They include a large class for laboratory research, professors' and lecturers' laboratories for the departments of public health and bacteriology respectively, seven in number, preparation rooms, a large theatre, and a library for

the joint use of the two departments. Particular attention has been paid to the lighting, which is a matter of no small importance to laboratory workers. The Dean of the Medical School, Dr. William Hunter, is to be heartily congratulated upon his energy and enterprise, for he has spared no pains to render the new department in every respect worthy of its new title of "University Laboratories in Public Health." The change thus effected marks another step in the development of the teaching of the University of London, in addition to the greater linking together of the work of medical students and post-graduates.

The Study of Medical History.

It cannot be said that the historical side of medicine has been unduly cultivated in this country. On the contrary, the subject of medical history, as such, is one to which the average medical practitioner, unless he be fond of antiquarian pursuits, is not specially attracted. The story of how some epoch-making medical discovery was made should, at least, be familiar to the medical student quite early in his career. Some attempt has been made of recent years by the establishment of the Fitzpatrick lectures at the Royal College of Physicians of London, to create an interest in the subject, and many valuable contributions to the literature have thus been made. The establishment of a Section of the Royal Society of Medicine for the Study of Medical History marks an appreciable advance in the study of this comparatively neglected aspect of medical science. The inaugural meeting will take place on Wednesday, November 20th, at 5 p.m. It is stated that the new Section already contains 128 members. One feature of the meetings will consist of exhibits by members from different parts of the country, and this should prove a popular innovation. It is also intended to develop an educational side through the medium of lectures by recognised authorities on the subject, open to all practitioners and medical students.

Genius and Drugs.

It is an old charge against men of genius that they are given not uncommonly to stimulating their faculties by the use of drugs. It has been too hastily assumed that such a habit was universal among men of genius. The physiological reason why the best, or, perhaps, the second best work, was produced by the help of drugs has not been clear, but in a recent article in the *Forum*, Dr. Reade, of the North Western University, supplies us with an answer. What is required for production of the best intellectual or moral work is "a systematisation of the personality." This in some cases may not accrue except as the result of an external stimulus. We all know cases where sudden and unexpected trouble or danger calls forth qualities previously unsuspected. The divergent impulses have been controlled and systematised. This is why in times of national stress, both the best and the worst phases of national life appear. The mere conventional becomes hidden by the individual qualities. In the absence of external stimulus a similar result may be produced by the use of one or other of the stimulant poisons. They have the power of enacting a harmony of the faculties. Different individuals find different drugs suit them best. Thus Dr. Johnson took tea, Voltaire coffee, Maeterlinck tobacco, Addison, Poe, and many others alcohol. Moreover, according to Dr. Reade, the stimulus of the pain of disease may bring about a similar harmony.

Tuberculosis and the Leading Hospitals.

In the organisation of the treatment of tuberculosis which is now proceeding all over the kingdom, there is some danger that the education of the practitioners of the future may be overlooked. The tendency is to shepherd all cases of tuberculosis occurring in the working classes to the special folds of the sanatorium and the dispensary. If this policy be pressed too far it may easily happen that medical students will be deprived of the opportunity of studying one of the most important diseases in its clinical aspects. It is not necessary to labour the point that without such opportunity the young doctor of the future will be insufficiently equipped to go among the public as a practitioner of medicine. No doubt, as at present, a number of patients suffering from tuberculous disease of one kind or another, will present themselves at the teaching hospitals. If, however, it became the custom to send on such cases at once to a special dispensary apart from the hospital, there will be a lack of the necessary clinical material. The easiest way out of the difficulty seems to be the attachment of tuberculosis dispensaries to the teaching hospitals. We do not, indeed, see why each general teaching hospital should not have as part of its out-patient equipment, a tuberculosis dispensary, recognised by and subsidised by the local health authority. In some instances it might be advisable to establish tuberculosis wards for in-patients, and, at any rate, provision should be made for the teaching of surgical tuberculosis.

Modern Isopathy.

The *Post-Graduate* publishes some interesting extracts from an isopathic catalogue issued under the date of 1886, prepared by one Dr. Samuel Swan. Hahnemann's reaction from the absurd, and sometimes disgusting, practices of his time was followed about 1840 by isopathy, an attempt to treat diseases "by the exhibition of their own morbid products." It is uncertain who was responsible for this offspring of homeopathy, but the remedies were triumphs of morbid ingenuity—discharges and excreta were ingested up to the coprophagous limit. The following are a few of Swan's "High Potencies, Morbific Products, Nosodes and other remedies":—Acarus; Scabies; Achrocordon Chococ. South American serpent, inveterate ulcers and sores; pains in scrofulous patients. Adenia; Glands from a case of Hodgkin's disease. Albuminuria; Renal Albumen; Anthracin; pus from a carbuncle; Blatta American (Cockroach); Bone Pus; Carcharadon Rondoletti; Chinese shark's oil. Too Choo's Balsam of shark's oil. Chinese remedy for deafness; Colastrom; Constipation of new born infant; Eel skin; Fel Gryllus Americana; Brazilian Cricket. Suppression of urine with or without pain. A boy who had chills and fever swallowed a live cricket and never had a chill afterward. Helix Tosta (Roasted Snail). Hæmorrhages from lungs and internal organs. Consumption: excellent. Lachryma Filia. Tears of a young girl in great grief and suffering. Protagon Humanum. From a dark complexioned man, aged forty-five, who had Bright's disease and Ascites. Pus from a Rectal Abscess. Sal cerebri. Salt secreted profusely from a gentleman's scalp with the perspiration, and on drying it was crystallised so heavily his head looked frosted. Vomito. Blood from a yellow fever patient while moribund. There were twenty-eight pages of this spelling, punctuation, and barbarous Latin. The virtue of these remedies is evidently transferable. "When a vial of medicine is nearly emptied, fill it with unmedicated pellets, and you will not have to purchase the remedy.

a second time." This catalogue was obtained quite recently from a leading homœopathic pharmacy in New York. It defies comment.

Death Attributed to a Patent Medicine.

DEATHS directly attributable to secret remedies are extremely rare for the simple reason that these concoctions very seldom contain any potent agents. If a nostrum is to be passed off as a cure for disease, simple or grave, upon which the vendor is well aware it can have no effect whatever, he recognises as a rule that coloured water, coloured paraffin, or a dose of cheap purgative will answer his purpose better than any ingredient which whilst perhaps more costly might lead to a charge of manslaughter. An inquest was, however, reported last week, in which a fatal issue was determined by the use of a patent medicine known as Nicholl's Pain Cream. A child, aged 9, when ill was given by her mother several doses of this preparation, and afterwards she became worse and died two days later. The mother stated that she only gave the prescribed dose of five drops on four separate occasions, but it was alleged that she had made a statement to a witness that the dose given was half a teaspoonful. Medical evidence was given that death was due to an irritant poison. It was stated that the doses of five drops would not have been sufficient to cause the child's death, but the larger doses of half a teaspoonful might have produced a fatal result. The jury returned a verdict that death was occasioned or accelerated by use of the medicine mentioned, and they expressed the opinion that restrictions should be placed upon the sale of preparations of this character, and that they should not be obtainable from ordinary shopkeepers. Deaths indirectly due to the use of medicines are not uncommon. Such cases are known to every practitioner among the poor; and cases are to be found at times in the wards of every large hospital. These fatalities, as we have so often pointed out, are brought about by the advance of curable diseases into a mortal phase during the delay, whilst reliance is being placed in cures that are, to put it mildly, unknown quantities, administered, moreover, by persons who know nothing of the most difficult of all arts and sciences—medicine.

PERSONAL.

H.M. THE KING has granted his Royal licence and authority to Major H. Ensor, D.S.O., M.B., R.A.M.C., to accept and wear the decoration of the Imperial Ottoman Order of the Medjidieh (Third Class), which has been conferred upon him by the Khedive of Egypt, authorised by the Sultan of Turkey, in recognition of valuable services rendered by him.

LIEUT. C. H. SMITH, I.M.S., has been selected for appointment as a Specialist in Advanced Operative Surgery.

DR. FRANK GEORGE BUSHNELL, M.D.Lond., D.P.H., has been appointed Tuberculosis Officer to the Essex County Council.

LIEUT. C. H. STRINGER, R.A.M.C., has been appointed Medical Officer-in-Charge of Rolleston Camp, Salisbury Plain.

THE name of Dr. A. M. Williamson has been added to the Commission of the Peace for the county and city of Edinburgh.

MR. CLAUDE H. G. FRANKAU, M.B., B.S.Lond., F.R.C.S., has been appointed Assistant Surgeon to St. George's Hospital.

MR. HENRY S. SOUTTAR, M.A., M.B., B.Ch.Oxon., F.R.C.S., has been appointed Assistant Surgeon to the West London Hospital.

DR. D. MURRAY LYON, M.B., Ch.B.Edin., M.R.C.P. Edin., has been appointed Assistant Pathologist to the Edinburgh Royal Infirmary.

SIR HENRY CRAIK was the chief guest last week of the Glasgow University Club at Manchester, under the presidency of Dr. A. Stewart.

COLONEL E. H. LYNDEN-BELL, R.A.M.C., has taken up the appointment of Assistant Director of Medical Services in the London District.

DR. H. NEVILLE CROW has been appointed Honorary Surgeon to the Worcester Ophthalmic Hospital in place of Dr. Seymour, who has resigned.

DR. T. STACEY WILSON has been elected President of the Birmingham Medical Mission in the place of Dr. T. E. Underhill, who has retired from this office.

DR. RAYMOND CRAWFURD will deliver the Fitzpatrick Lectures at the Royal College of Physicians of London during the present month.

DR. C. J. MARTIN will deliver the Horace Dobell Lecture at the Royal College of Physicians of London on Thursday, November 21st, on "Insect Porters of Bacterial Infection."

DR. H. P. NEWSHOLME, M.B., B.Ch., B.Sc., M.R.C.P., D.P.H., has been appointed Assistant Medical Officer of Health and Assistant School Medical Officer, Southend-on-Sea.

OUR sympathies are with Dr. Charles Matfias, of Tenby, who was shot on his own doorstep a week ago by a dastardly assailant, but we understand happily without any very serious results.

DR. H. COLLEY MARCH (Portesham), Dr. W. Burrough Cosens (Dorchester), and Dr. Peter William MacDonald (Dorchester) have been appointed Justices of the Peace for the county of Dorset.

THE Weber-Parkes Prize of 150 guineas and medal has been awarded by the Royal College of Physicians of London, to John Alexander Douglas Radcliffe, M.B., B.Ch. Roy. Univ. of Ireland, Pathologist to the King Edward VII. Sanatorium, Midhurst.

SIR CHRISTOPHER NIXON, Bart., M.D., LL.D., has been reappointed Vice-Chancellor of the National University of Ireland and Representative of the University on the General Medical Council, the tenure of office in both cases being for a period of three years.

DR. H. McNAUGHTON JONES presided at the annual festival dinner of the Irish Medical Schools and Graduates' Association, at the Hotel Cecil, on October 31st. He has occupied the presidential chair of that body for three years in succession, an honour not previously accorded to any occupant of that particular position. The chief speakers on that occasion were Sir James Barr and Dr. Esmonde, M.P.

A CLINICAL LECTURE

ON

JAUNDICE.

By W. LANGDON BROWN, M.D., F.R.C.P.,

Physician to the Metropolitan Hospital, and Medical Registrar to St. Bartholomew's Hospital.

FOR a long time cases of jaundice were divided into hæmatogenous and hepatogenous. In the latter group were placed those with a demonstrable obstruction to the bile ducts, while in the former were those in which no such obstruction could be found, and the condition was believed to depend upon a blood change. Such a view was very natural when it was known that the hæmatoidin of old blood clots was chemically identical with bilirubin, and that any drug which broke down red corpuscles caused jaundice. But then it was found that the same drug which caused hæmolysis also caused a catarrh of the smaller bile ducts, and if the liver were excluded from the circulation hæmoglobinuria resulted instead of jaundice. The jaundice was therefore really obstructive in nature, the situation of the obstruction merely being in the smaller instead of the larger ducts. Since those days, however, we have learnt of the existence of more subtle hæmolytic changes than those produced by drugs. Under a number of conditions hæmolysins are produced in the body which do not excite hepatic catarrh. The changes in extravasated blood which lead to the formation of hæmatoidin are brought about by this blood exciting the production of an antibody hæmolytic in its action. According to Troisier and Laroche, the hæmolysin acts by attaching itself to the extravasated corpuscle, altering its osmotic properties so that the hæmoglobin becomes extruded. A number of infective fevers and parasitic diseases apparently produce a similar condition in the blood. The presence of the malarial parasite in the red corpuscle might reasonably be expected to alter its osmotic state, and the occasional occurrence of jaundice in this disease is probably thus brought about. In the anæmia due to the presence of ankylostoma in the duodenum a hæmolytic jaundice occasionally occurs. The slight jaundice of secondary syphilis is of a similar type. Incidentally its occurrence may vitiate Wassermann's test, owing to hæmolysis occurring in all the tubes, as has happened in two cases under my own care. Some French observers place the jaundice of pneumonia and typhoid fever in this category. Jaundice is commonest in pneumonia, however, when it is the base of the right lung that is involved, which suggests a direct extension of the inflammatory process through the diaphragm, causing a catarrh of the smaller bile ducts. And as typhoid bacilli invariably ascend the common bile duct into the gall bladder it is only to be expected that they sometimes set up a cholangitis. It is indeed only surprising that they do not do so more frequently. We should require more evidence than is before us at present before accepting a hæmolysis as the explanation of jaundice in these diseases. The marked lemon tint of pernicious anæmia is, however, probably due to this cause, and the constant excess of urobilin in the urine points in the same direction. While severe jaundice in the newborn is generally due to septic infection from the umbilical cord or to pericellular cirrhosis of con-

genital syphilis, and exceptionally to atresia of the bile ducts, there is very often a slight transient jaundice which has been referred to hæmolysis. Before birth the fœtus has a polycythæmia, the average being $6\frac{1}{2}$ millions per cmm. By the second day after birth this excess has disappeared and probably there will not be more than $4\frac{1}{2}$ millions. In a sense the polycythæmia may be regarded as protective against the risks of birth, and the modern practice of waiting until as much as possible of the placental blood has entered the child's body before tying the umbilical cord may be regarded as tending to maintain the excess of corpuscles after the need for them has passed. Hæmolysis would therefore follow. This is not an argument against the practice, as the excess does no harm and the jaundice causes no inconvenience. According to other observers, however, no real difference can be detected in the blood counts, whether the cord is tied at once or when it has quite ceased pulsating. Thomson offers another ingenious explanation. During foetal life the ductus venosus provides a short cut whereby the placental blood, coming from the umbilical vein can go direct into the inferior vena cava without passing through the liver. If it does not close immediately after birth, portal blood containing bile pigment absorbed from the intestinal meconium can pass direct into the general circulation. In support of this hypothesis it may be noted that transient jaundice is more common in premature children, where delay in closure might be expected. I have certainly found a patent ductus venosus in *post-mortem* examinations of premature children, but they have not always been jaundiced.

But the clearest, as it was the first established instance of a hæmolytic non-hepatic jaundice, is that called congenital family cholæmia or acholuric jaundice. The patient may be born jaundiced, but more commonly becomes so in the first few years of life. The jaundice persists with little or no variation for many years, but bile pigment is present in the stools as in health, while it is absent from the urine, in which any darkening is due to excess of urobilin. Nevertheless bile pigment is present in the serum. The spleen is always enlarged while the liver is not. There is considerable anæmia with a low colour index, poikilocytosis, nucleated red cells and reduction in the number of leucocytes. Yet the patient has fair or good health and shows a normal resistance to intercurrent diseases. The condition tends to appear in more than one member of the family and in successive generations. Some of the patients are liable to attacks of pain over the liver or spleen with slight pyrexia, during which the colour deepens. Alcohol and syphilis do not appear to take any part in its ætiology. Enlarged abdominal veins, ascites, œdema of the legs and hæmatemesis have never been recorded. Attacks of hæmoglobinuria have been noted, which could be induced by exposure to cold, and in this connection it is interesting that in one family a cold bath would intensify the jaundice. The most striking patho-

logical feature of the condition is the undue fragility of the red corpuscles, for they are hæmolyzed by a dilute salt solution which has no effect on ordinary corpuscles. The French school have adduced experiments which seem to show that this undue fragility is due to the corpuscles having been sensitised by the adsorption of a toxin, but we are at present completely in the dark as to its nature.

We may sum up the characteristics of hæmolytic jaundice thus:—Though bile pigment is present in the serum it is only exceptionally present in the urine, and it is always present in the stools. Bile salts are not found in the blood, and, accordingly, there are not the bradycardia, the headache, depression and pruritus typical of obstructive jaundice. The corpuscles show diminished resistance to the action of salt solution compared with normal blood. Their fragility is further evidenced by their diminished numbers, their irregular forms, and in some cases their granular appearance.

It is one of the commonplaces of medicine that in the young adult obstructive jaundice is most often due to catarrh, in the middle-aged to gallstones, and in the old to malignant disease of the liver or the head of the pancreas. Here I wish to consider some of the features common to all forms of obstructive jaundice resulting from the alteration in the course of the bile, and to contrast these with hæmolytic jaundice.

Blood and Lymph.—It has been shown that when the bile duct is occluded the bile reaches the blood stream by way of the lymph. This may occur rapidly, for bile pigment may be found in the blood serum two hours after experimental ligation of the bile duct, and therefore much sooner than it appears in the conjunctiva or skin. Although bile salts have a solvent action on the lecithin and cholesterin of the red corpuscles *in vitro* the patient's own circulating corpuscles acquire a heightened resistance which increases with the intensity of the jaundice. This sharply differentiates such cases from hæmolytic jaundice. Though anæmia may result from the same cause of the jaundice, as in malignant disease of the liver, it is not a characteristic feature of other forms of obstruction to the bile duct. Occasionally small subcutaneous hæmorrhages may be seen, but they are usually produced by scratching excited by the pruritus or are really small telangiectases. As has already been said, the red corpuscles are more stable than normal, instead of being unduly fragile as in hæmolytic jaundice.

The Alimentary Canal.—We usually infer the existence of obstruction to the bile duct from the absence of pigment in the fæces and the cessation of obstruction by the return of the colour. But excess of the fat in the stools—*e.g.*, from pancreatic disease—may mask the presence of bile pigment. In many cases of jaundice extraction of the fæces with acid alcohol will show that pigment is present and therefore the obstruction is incomplete. This is more likely to be the case with gallstones than with new growth in the head of the pancreas, and may therefore be of diagnostic value. The amount of fat may be so great that the fæces float in water. An obvious amount of pigment in the fæces throughout suggests a toxæmic cause for the jaundice, in which there is no obstruction to the main duct.

The main digestive value of bile is in relation to the fats. The bile salts permit of closer contact between the watery digestive juices and oily fluids by lowering surface tension, while the lecithin and cholesterin help to dissolve fatty acids and soaps. Even in acid media the action continues because the bile acids which are now set free conjugate with fatty acids. Bile salts also play an im-

portant part in the absorption of fat by lowering surface tension. We can therefore determine in a case of fatty stools whether the pancreas or the bile is at fault. In normal fæces the saponified and unsaponified fats are approximately equal in amount. Now the pancreas provides for the fat-splitting that must precede saponification, so that if the excess of fat be due to a pancreatic defect, unsaponified fat will be in excess of the saponified. On the other hand, bile salts provide for the absorption of the fat already digested by the pancreatic juice, so that if there is loss of bile, the saponified fats will be in excess, because they cannot be adequately absorbed. It is due to this difficulty in the absorption of fat that jaundice is so commonly associated with wasting, even when not due to a wasting disease like cancer. Theoretically it should be possible to counter-balance this by a liberal diet of carbo-hydrates, which can be digested and absorbed in the absence of bile. Practically, however, the accompanying digestive disturbance makes this difficult, so the patient is compelled to consume his tissue fat.

Bile is a natural laxative, as the bile salts stimulate the peristaltic movements. Jaundice is, therefore, apt to be accompanied by constipation. It is claimed that bile is antiseptic in its action, and it is certain that in its absence from the bowel there is excessive putrefaction as evinced by the rise of ethereal sulphates in the urine. But though free bile acids are antiseptic, bile salts are not. Bile cannot indeed keep itself from putrefaction, so that it cannot be regarded as an antiseptic. The explanation is that in the absence of bile salts the fats are so slowly absorbed that they coat over the proteins, which, therefore, undergo excessive bacterial decomposition instead of being quickly assimilated. The peculiar odour of the stools in jaundice is largely due to the higher fatty acids.

Hyperchlorhydria is a common accompaniment of jaundice, though not if there is also gastro-duodenal catarrh. Probably the hyperchlorhydria results from protective spasm of the pyloric sphincter, leading to retention of the gastric contents. It is, therefore, most likely to occur when the jaundice is associated with pain, as in gallstones, or with diseases of the pancreas, where the acid is inadequately neutralised by the alkaline pancreatic juice.

The Urine.—Bile pigment reaches the urine soon after its appearance in the blood, and before it can be detected in the conjunctiva. Naturally it disappears from the urine last as the jaundice clears up, since this is the way the body gets rid of it. The play of colours with fuming nitric acid is the best test, green being the most significant tint. Rosenbach's modification of Gmelin's test is the simplest; a piece of white filter paper is dipped in the urine and a drop of the acid is placed on it. The green colour obtained by the addition of tincture of iodine is not so sensitive. Bile salts may be found in the urine even before the pigment. Matthew Hay's test is the only one of any value for detecting them here. Flowers of sulphur poured on to the urine sink if bile salts are present, owing to the reduction of surface tension. But the majority of cases do not show bile salts in the urine. Some years ago I made a series of observations in the hope that their presence or absence would throw some light on the cause of the jaundice in different cases, but I found no help from this. The bile salts, which enter the bowel, are reabsorbed and used over again several times. Copeman's observations show that soon after a biliary fistula has been established the salts in the bile fall to one-tenth of the normal, since reabsorption cannot occur now. This suggests that

normally bile salts are secreted and reabsorbed ten times before being used up.

Urobilin is absent from the urine in cases of complete obstruction of the bile ducts, as it is a reduction product formed by bacterial action on bile pigment in the bowel. If bile does not enter the intestine urobilin cannot be formed. When bile is again beginning to enter the intestine urobilin becomes abundant in the urine, probably because the excessive putrefaction going on in the intestine leads to its excessive formation. In obstructive jaundice, therefore, the occurrence of urobilinuria is often prognostic of subsidence of the jaundice. Indican is usually increased in the urine of jaundice since it results from intestinal putrefaction. A trace of albumen is frequently present also from irritation of the kidney by the bile, and this is accompanied by a relatively large number of yellow hyaline casts.

The Heart and Vessels.—One of the most definite results of jaundice is bradycardia. High tension usually accompanies a slow pulse, but in the bradycardia of jaundice the pressure is low and the pulse dicrotic. High tension stimulates the cardio-inhibitory centre in the medulla, and thus slows the heart through the vagus, but bile salts have a directly depressing effect on the heart. Hence the slow pulse with low blood-pressure. The blood pressure is also kept low by the toxic action of the bile salts on the smaller blood vessels producing some degree of vaso-motor paralysis.

The Central Nervous System.—Any severe toxic jaundice will be accompanied by marked nervous symptoms—headache, delirium and ultimately coma. But this is due to hepatic inadequacy and not to the presence of bile in the circulation. Indeed, bile salts are probably not produced in this condition, the liver being too damaged to elaborate them. A mild degree of poisoning of the nervous system by bile salts is, however, common in ordinary jaundice, causing depression and headache. Bile pigments and bile salts are usually found in the cerebro-spinal fluid removed by lumbar puncture.

The Skin.—Bile pigment appears in the skin soon after it does in the conjunctiva. It is well known that the lemon tint of pernicious anæmia can readily be distinguished from ordinary slight jaundice by the fact that the conjunctiva is not yellow but pearly white. If the lemon tint is produced by hæmolysis this difference in distribution is not easy to understand. In chronic jaundice flat nodules of xanthelasma are not uncommon. The production of subcutaneous hæmorrhages and telangiectases has already been alluded to. Pruritus is a most troublesome symptom, but it is inconstant. It is most likely to develop in cases of jaundice with sudden onset. It bears no relation to the severity of the jaundice, but may come on in the late stages of protracted cases. Pruritus is to be attributed to the bile salts. The patient indulges in much scratching, but without relief, for, as he often says, the itching is *beneath* the skin. Gilbert and Herscher found that thyroid extract inhibits or diminishes the formation of bile salts, and I have confirmed this both experimentally and clinically. I have found it decidedly useful for the relief of pruritus.

The Secretions.—Saliva, tears, and milk are not bile-stained. It is quite exceptional for the sweat to be thus stained, despite frequent statements to the contrary. The copious diaphoresis induced by pilocarpin is, however, accompanied by bile pigment. Nasal and bronchial mucus is not tinged with bile. Inflammatory and passive exudates, on the other hand, are invariably bile-stained. Thus if

mastitis occurs in jaundice, milk would be coloured with bile. Again, although the expectoration in bronchitis is not coloured, if pneumonia or œdema of the lung occurs, bile at once appears in the sputa. In a case of jaundice without pneumonia, then, the occurrence of bile-stained sputa is of serious import, being evidence of heart failure. Fluid in the pleural or peritoneal cavity, being either the result of inflammation or of passive exudation will accordingly be coloured by bile in a jaundiced patient.

It will be observed that apart from an unpleasant but harmless discoloration produced by bile pigment, all the important symptoms in jaundice are due to bile salts. Their absence from the intestine causes steatorrhœa and wasting from deficient absorption of fats, increased intestinal putrefaction and constipation. Their presence in the blood causes bradycardia, headache, depression, pruritus, and sometimes subcutaneous hæmorrhages.

In conclusion we may note that obstructive jaundice is sharply distinguished from hæmolytic jaundice of the type described in the earlier part of this lecture by the presence of these symptoms of the perverted course of the bile salts and by the normal or heightened resistance of the red corpuscles. When the obstruction is complete there is of course the additional diagnostic feature of clay-coloured stools. But this will be lacking if the obstruction is partial or passing off, although the patient will still be jaundiced.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Professor Hutinel, M.D., of the Faculty of Medicine of Paris; Physician to the Hôpital des Enfants Malades. Subject: "The Early Symptoms of Tuberculous Meningitis."

ORIGINAL PAPERS.

A NOTE ON INJURIES AT OR NEAR THE ANKLE.

By J. JACKSON CLARKE, M.B., F.R.C.S.,
Senior Surgeon to the Hampstead General Hospital and Surgeon to
the Royal National Orthopædic Hospital.

A GREAT number of injuries important clinically occur in the neighbourhood of the ankle-joint. Since the introduction of radiography sixteen years ago some of these conditions have come to be understood better than they were formerly, and no one worker has contributed more to the surgery of this region than Etienne Destot, of Lyons, in his book, "Traumatismes du Pied et Rayons X."

The salient anatomical and physiological features of the region should be clearly borne in mind. No common injury demands of the practitioner more care in diagnosis than a case of recent injury in the neighbourhood of the ankle-joint. The patient may be seen immediately before swelling has occurred, or when swelling has obscured the anatomical landmarks. The swelling may extend from the mid-tarsal region to the middle of the leg. A history of the accident, whether the injury was caused by a fall on the foot in a position of flexion or extension, or whether the foot was turned forcibly outwards or inwards, or subjected to a direct crushing, such history may guide the course of clinical examination; careful palpation, tapping at various spots for loose fragments (*toucher du piano*), tapping the heel to find whether there is effusion into the ankle as indicated by an *astragalar shock*, akin to the *patellar shock* in knee-joint effusion. All these and other points of clinical examination should be carefully carried out, and also in every case, without exception, the patient

should be advised to have a skiagram taken without delay.

It cannot but be useful to recall the various possible injuries in this region beginning at the lower extremities of the tibia and fibula and ceasing at the transverse tarsal joint.

The following groups of injuries require notice:—

- 1.—Supra-malleolar fractures of tibia or fibula or both, separation of lower epiphysis of the tibia.
- 2.—Sprains of the ankle.
- 3.—Dislocations of the ankle.
- 4.—Malleolar fractures, including Pott's fracture; separation of lower fibular epiphysis.
- 5.—Fractures of the lower articular surface of the tibia.
- 6.—Fractures and dislocations of the astragalus.
- 7.—Fractures of the os calcis.
- 8.—Sub-astragal sprain, and sub-astragal dislocation.
- 9.—Fractures and dislocation of the scaphoid.
- 10.—Dislocation at the transverse tarsal joint.

The importance of comparing all the varied conditions that fall into the above categories is not in doubt. What appears to be a simple fracture of the external malleolus may be but the less serious part of an injury involving a fracture of the astragalus of a kind which demands operative treatment, or a fracture of the os calcis such as entails a certain amount of permanent weakness for which the patient will blame the doctor if due warning is not given at the commencement of treatment. Nor is it sufficient to study merely the results of injury. The common spontaneous flat-foot is closely imitated by the results of injury to the ankle or to the posterior tarsus and must be considered with them.

The anatomy of the parts is so important that it is necessary to have the bones before one as one reads. The lower ends of the tibia and fibula should be fitted together, and note should be taken of the form of their corresponding astragal articular surfaces; the large buttress of bone, posterior apophysis, that supports the long low hinder lip of the inferior tibial surface; the bi-malleolar axis with its 30 degrees of obliquity—the outer malleolus being so far behind the inner; of these among other points concerning the lower end of the leg bones. The ligaments which bind and the tendons which support and move the bones must all be kept in mind as well as the mechanics, static and dynamic, of the region. At the ankle-joint the bones subserve two separate functions: first, that of sustentation, or transmitting the weight of the body to points of the astragalus, which vary according to whether the foot is at right angles with the leg in the plantigrade position or plantar-flexed (digitigrade or equinus position) or dorsal-flexed (calcaneus position): second, that of maintaining a certain direction of the foot, by reason of the astragalus fitting between the two malleoli as in a mortise. The second function is subservient to the first, but from the point of view of treatment the two must be thought of separately.

The astragalus plays the chief part in determining the majority of the injuries under consideration. The upper aspect of its body forms the quadrant of a pulley-like surface; whilst below it is closely bound to that most important bone of the tarsus, the os calcis by the interosseous ligament. These two bones form the posterior section of the tarsus. Together with the os calcis the scaphoid and the inferior calcaneo-scaphoid complete the bed of the astragalus.

The main groups of injuries may now be considered.

Group 1.—Supra-malleolar Fractures.—Fractures

of one or both leg bones immediately above but not involving the ankle-joint owe their importance to the danger of ankylosis. The lower epiphysis of the tibia being extra-articular, cases of its separation also belong to this group. Treatment is the same as in other cases of fracture of the shafts of the leg bones, but in this region it is important to secure a good apposition of the fragments and, by massage and movements, unimpaired function. If it should be found to be impossible to obtain good apposition, often operation is called for.

Group 2.—Sprains of the Ankles.—These are injuries to the ligaments or other soft parts without fixed deformity. Radiography has shown that in many cases which appear clinically to be simple sprains of the ankle, bone lesions may be found—e.g., incomplete fracture of the fibula, separation of the tip of the external malleolus, fracture of one or other malleolus, usually the external one, of the anterior border of the inferior tibia at the inferior tibia-fibular joint. Therefore a skiagram should be taken in every case.

The simplest treatment of a sprained ankle is that described by Wharton Hood: The application of a rather stiff slight adhesive plaster (a) next the skin, and outside this a series of strips of adhesive rubber plaster overlapping one another from above down to render centripetal massage easy. None of the strapping is to be applied tightly but just comfortably, and renewed as the subsidence of swelling requires. Walking is resumed at once, but in cases where there is reason to think serious ligaments may have been ruptured, an outside iron and inside T-strap should be worn before walking is allowed. Wharton Hood. "Treatment of Injuries." 1912.

Group 3.—Pure dislocations of the foot can only occur in two directions, forwards or backwards; either may be *complete* or *incomplete*, according as the trochlear surface of the astragalus completely leaves that of the tibia or not. For reduction the

Fig. 1.—Schematic representation of the classical fractures of the fibula, accompanied by partial or total dislocation of the foot outwards. (1) Normal bones, showing epiphyseal lines and the ages at which they disappear; (2) normal bones, H, high; M, median; L, low fracture sites of fibula; (3) bi-malleolar fracture; (4) fracture of the shaft of the fibula and either fracture of the internal malleolus or rupture of the internal lateral ligament of the ankle-joint: Pott's fracture; (5) fracture of the fibula near its upper end from complete outward displacement of the foot: Maisonneuve's fracture.

patient lies on the back with hip and knee-joints bent, the limbs being firmly held below the knee, while the operator manipulates the foot. Division of the tendon of Achilles may be required in forward dislocations.

(a) These plasters are supplied by Fitch and Ibbotson, 2, Lower Seymour Street, W.

Group 4.—Malleolar fractures, including Pott's fracture and separation of the lower fibular epiphysis. These may be divided into two classes: Class 1.—Fractures without displacement of the foot occur more commonly than is supposed; many severe and some simple sprains involve incomplete fracture of the lower part of the fibula or separation of the tip of one or other malleolus. A special fracture is that described by Wagstaff, in which the anterior margin of the surface of the fibula which articulates with the tibia is separated. The inferior tibio-fibular ligament may be torn without any bone being fractured. This injury is produced by a diastasis—i.e., a temporary dislocation which rights itself. It is to be remembered that a fracture of the fibula with the concomitant injury to the parts at the inner side of the ankle characteristic of Pott's fracture may be present without the corresponding deformity, the subluxation of the ankle having righted itself.

Class 2.—Malleolar fractures with displacement of the foot, see Fig. 1, which shows types of malleolar fractures classified according as different parts of the fibula are involved.

(a) The usual definitions as given in English works are as follows:—

What we call a Pott's fracture is called a fracture of Dupuytren type by Destot. Pott's description of the fracture associated with his name was published in 1775—"Chirurgical Works of Percival Pott." The late Mr. Pickering Pick, "Fracture and Dislocations," 1885, refers to the English conception of Dupuytren's fracture to a description of a case in the *Hôtel Dieu* in 1816. The exact lesion appears to have been conjectured only: "The fibula is fractured, and the tibio-fibular ligaments torn through; or what is more probable, a small portion of the tibia into which these ligaments are attached broken off, etc." In Dupuytren's "Injuries and Diseases of Bones" the chief stress is laid on typical cases of Pott's fracture. Now we are able by means of the X-rays to make an "Autopsy vivante," and definite anatomical diagnosis is possible, I think it will be an advantage to give up the term "Dupuytren's fracture" and also as far as possible descriptive names for those that may be termed monumental.

Pott's Fracture.—The fibula in this injury is broken about $3\frac{1}{2}$ inches above the top of the malleolus. The foot is displaced outwards and backwards, and the heel is drawn upwards. This three-fold displacement is a necessary part of a Pott's fracture. The foot may be everted to 90 degrees, but the degree of displacement is no guide as to prognosis. This displacement is only made possible either by laceration of the internal lateral ligament or separation of the internal malleolus; and to allow of the outward displacement some degree of laceration and stretching of the inferior tibio-fibular ligaments must take place. An oblique fracture of the external malleolus causes a deformity similar to that of Pott's fracture. Fractures of this type are

(a) Various terms are used to explain the inverted and everted positions of the foot. If the foot is compared with the hand eversion corresponds with pronation, thus the everted foot is often called the pronated and the inverted the supinated foot. The terms adduction and abduction are also used for the same movements, as far as they are carried out at the subastragalus and medio-tarsal joints, but there is no pure movement of adduction or abduction, since the movement between the astragalus and os calcis is a rotary one on an axis passing from the upper and inner part of the head of the astragalus downward and outward to the outer tuberosity of the os calcis. It comprises at least two-thirds of the whole movement. Part of the inversion-eversion movement takes place at the ankle joint, and, owing to the form of the tibio-fibular mortice, this movement, as one can easily see in one's own foot, is more free in the ventro-flexed position. It is of practical importance to remember that when the knee is extended, the normal ankle should be capable of 22 degs. of dorsal and at least 45 degs. of ventral flexion.

not uncommonly compound; the soft parts over the inner side of the joint yielding either to stretching or to external pressure. Treatment of malleolar fractures consists first in reducing the deformity completely, whether by massage or under anæsthesia, and adopting some form of splint to maintain the correction, a back splint with footpiece at right angles and side splints properly applied after complete correction of the deformity will be found to be most generally useful. In practised hands the double houseflannel and plaster of Paris (Croft's) splint may be used. Early massage and movement are essential.

Flat-foot, after Pott's fracture, (a) may be of the ordinary kind caused by muscular weakness, but it is very often an expression of imperfect reduction of the dislocation. Where union has taken place in a bad position operative treatment alone can correct the deformity. Early ambulant treatment may be allowed if the proper steel support is used. This is an external steel support with an internal T-strap and a valgus pad in the boot being the most effectual treatment for the flat-foot. It can be made and adapted to any boot in a few hours.

Open operation is required when the deformity cannot be completely removed under anæsthesia, and also in compound fractures. Efficient drainage is important in the latter.

Group 5.—Fractures which involve the inferior articular surface of the tibia, the weight-bearing part of the bone: Class 1, Bimalleolar fractures with fracture of the posterior margin of the inferior tibial surface; 1a, Isolated fracture of the inferior tibial surface (Meissner). Class 2. Fracture of anterior margin of tibia. Class 3. Various multiple fractures of the lower surface of the tibia.

These are very serious injuries and demand open operation of some sort. Astragalectomy is recommended by Destot in Class 1, and I have found it necessary in one such case. A perfect ankle cannot be expected after any of these accidents.

(To be continued.)

THE TREATMENT OF PSORIASIS.

By DRS. BROCC AND SIMON.

Of the Faculty of Medicine of Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

PSORIASIS is the name given to an affection of the skin which is not, as a rule, attended by itching. It makes its appearance in successive outbursts and is characterised by circumscribed patches of a more or less bright red colour, covered with pearly scales, usually thicker at the centre than towards the periphery. When we scrape a patch we remove, easily or with some trouble, successive layers of white, pearly, stratified scales until ultimately we perceive the pink colour of the subjacent tissues. If we go on scraping gently we finish by raising a sort of fine pellicle which comes away in comparatively large pieces and beneath this is the red, smooth, shiny, often rather moist, dermic surface on which soon appear fine droplets of pure blood. It is only after carrying out this exploratory scraping that we can be sure we are dealing with a case of psoriasis.

The clinical forms of psoriasis are rather variable; according to the extent and shape of the elements they are known as *psoriasis guttata*, *nummulata*, *punctata*, *gyrata*, *figurata*, &c. Its

(a) The eversion of the foot in such cases is due to the external malleolus being tilted outwards and the astragalus following it. This is not ordinary flat-foot, which is a sublimation of the astragalo-scapoid and other tarsal joints.

favourite site is the elbow or rather the upper posterior aspects of the forearm, the knees and the scalp. The last-named is characterised by fine scales or, more commonly, by stratified collections of epidermis running through the still healthy hair, giving rise to typical ridges.

We also get it on the face, the prepuce, the glans, the palms of the hands and the soles of the feet, where it may be difficult to distinguish the eruption from psoriasisform syphilides. On the nails we get typical yellow stains, detachment of the nails and cupuliform erosions. It is not uncommon for psoriasis to accompany deforming progressive arthropathies (arthropathic psoriasis.) In nervous and intoxicated subjects there may be itching.

INTERNAL TREATMENT.—(1) Good hygiene, bodily exercise and perspiration. (2) Same dietary as for gouty arthritides; in the subjects of pruriginous psoriasis forbid alcohol, coffee, tea, &c. Apart from any other treatment strict vegetarian diet often yields surprising results. (3) No remedy yet known yields constant results in psoriasis. Sometimes arsenic, taken in large doses over a long period, causes the eruption to disappear, so does iodide of potassium. Mercury proves successful in the arthropathic form. Balsams, e.g., tolu, copaiba, sandalwood oil, turpentine and so on, sometimes appear to promote the subsidence of the attack. In some instances thyroid extract exerts a marked, direct action on the patches.

LOCAL TREATMENT.—I. (A) Inflamed Psoriasis.—Avoid using any irritating substance. (1) Starch or gelatine baths every day or every other day at the temperature of the body, lasting 20 minutes. Dress the patches immediately after the bath. (2) On the spots most affected, especially if they weep, apply cold potato poultices or cover with rubber tissue or with lint steeped in camomile water and covered with protective. (3) Morning and evening rub the whole body with freshly-prepared lard, vaseline, glycerole of starch, cod-liver oil or oxide of zinc ointment. (4) As the irritation of the skin subsides try and get the patient to use benzo-naphthol ointment, made progressively stronger, beginning with 1 in 40.

(B) Non-Inflamed Psoriasis. *Take the case of a patient with a copious eruption who for any reason cannot remain under close observation but who can spare the time to attend to himself.* In such a case prescribe preparations containing tar or oil of cade. (1) Every day to take a sulphur or alkaline bath during which the patches are well-rubbed with tar or salicylic soap so as to get rid of the scales. If no bath be available scrub the whole body vigorously every evening with hot boiled water and soap. (2) Directly after the bath rub the following ointment energetically into the patches:—Cade oil, 100 parts; soft soap, q.s. to emulsify the oil, glyceride of starch, 94 parts; salicylic acid, 3 parts; essence of cloves, 10 parts. Should this ointment cause inflammation, we have only to reduce the proportions of oil of cade and salicylic acid. (3) When the ointment has been applied, the patient puts on flannel combinations which absorb the oil of cade over the sites of the patches. This is worn throughout the treatment so as to keep the parts in a perpetual bath of oil of cade. (4) If the patient is engaged during the day these applications are only made at night. In the morning he washes all over with a scented soap of some kind

and applies a little salicylic ointment to the patches. (5) Should cadic acne supervene we must suspend the treatment, giving starch baths and applying sedative ointments until the inflammation has subsided, then recommence the treatment.

II.—*The patient has a copious eruption of psoriasis and cannot be kept under observation by the physician and for special reasons cannot make use of smelly ointments.*—(1) Take every other day a simple or sulphurous bath in which the patches are scrubbed clean with tar or salicylic soap, soap well all over every night. (2) Every night, on going to bed, apply a salicylated pyrogallic ointment but proceed cautiously, looking out for darkening of the urine. Begin with an ointment containing eight grains of salicylic acid and sixteen grains of pyrogallic acid in ten drachms of vaseline and apply this only on one limb for example. If it be well borne its use may be extended and the proportion of salicylic acid increased to 1 in 10. As pyrogallic acid stains the hair we must use mercurial ointments in light-haired persons with psoriasis of the scalp. (3) If pyrogallic acid does no good, try calomel ointment, 1 in 50, gradually increased to 1 in 20, or the ointment of the yellow oxide of mercury. Be on the look-out for salivation and only apply it over limited areas. (4) We may also try sublimate baths (10 to 20 grammes to each bath). (5) Should these measures for any reason be inapplicable, revert to the naphthol preparations, 2 in 10, and salicylic acid 1 in 75.

III.—*The patient cannot keep in touch with the doctor but has only a few patches of psoriasis.*—(1) For psoriasis of the scalp prescribe a mercurial ointment (yellow oxide, for instance). The patches must be washed from time to time with Panama wood or tar soap, then rub the patches gently with the ointment. (2) For the body we may prescribe mercurial or cade oil ointments containing 1 in 20 of the yellow oxide instead of salicylic acid, but it is always preferable to have recourse to medicated collodion or traumaticine or medicated plasters (e.g., oil of cade, calomel, pyrogallic acid, &c., plasters). The patch is carefully scraped clean, then a piece of plaster rather larger than the patch is placed in apposition and left on for 24 hours. The plaster is then removed and the spot cleansed with a plug of cotton steeped in ether; wash with soap and hot water, then renew the application.

IV.—*The patient can remain under observation.*—Of all the topics actually known the best is unquestionably chrysarobin or chrysophanic acid. The drawback to its use is its liability to set up very violent irritation, generalised erythema and other symptoms of intoxication. Its use must therefore be closely watched. (1) It should not be used to the scalp, mercurial ointments being used instead (*vide supra*). (2) Cleanse the patches now and then, removing the scales, by baths and soaping. (3) To one or two patches a day apply an ointment containing 1 part of chrysophanic acid, .75 part of salicylic acid and pure vaseline 40 parts. Gradually extend the area of application and increase the proportion of chrysophanic acid to from 1 to 30 to 1 in 10 and even 1 in 5. (4) Should the acid not be tolerated have recourse to pyrogallic acid (*vide supra*), to mercurial preparations, or, as a last resort, to oil of cade, pure or mixed with the yellow oxide of mercury.

In the treatment of psoriasis we must push it

until the eruption has completely disappeared and there remains not the faintest trace, otherwise speedy relapse is probable.

Much has been written of late about the effects of the X-rays and radium on patches of psoriasis. Unquestionably these agents cause the patches to disappear, but recurrence is the rule unless the exposure has been such as to determine atrophy, but this exposes the patient to the risk of radio-dermatitis or subsequent telangiectases which, when situated on the chest, back or arms in women, would then have to be treated by electrolysis.

THE MODERN COMBAT AGAINST TUBERCULOSIS AMONGST CHILDREN (a)

BY PROFESSOR NIETNER,
Of Berlin.

THE council and staff of the Royal Hospital for Diseases of the Chest recognise their duty as a special hospital for diseases of the chest to provide training for medical officers of tuberculosis dispensaries and sanatoria, and more specially for general practitioners, and through the generosity of one who fully realises the great value at this juncture of affording facilities for such training they have been able to build an entirely new outpatient department equipped with all details for research work and scientific instruction on modern lines, and with special accommodation for a tuberculosis dispensary. But it is not only hoped to constitute the hospital as a training centre for those who wish to qualify themselves for dispensary and sanatorium appointments but also as a special training centre for tuberculosis nurses. In Germany it has long been recognised that efficient training is indispensable for the domiciliary work connected with the dispensary system, above all, training in the collection and interpretation of data. The properly trained observer can be relied upon to procure the right sort of information, and this will conduce to promote economy, both of financial expenditure and of effort. Arrangements are being made to receive nurses for two years' training or for shorter courses of post-graduate teaching.

In these circumstances it was held that no one could be better fitted to give the inaugural lecture than Professor Nietner, who is the general secretary of the German Central Committee for the Prevention of Tuberculosis. This great society was founded in 1895 by the Reichs Kanzler of that day, Fürst Hohenlohe. It was designed to link up all schemes and associations throughout the German Empire which have as their object the prevention of tuberculosis. The President is the State Secretary of the Interior for the time being. The council includes representatives from the Federal States, the Imperial Board of Health and the Imperial Insurance Board, as well as a number of high officials and medical experts. The Central Committee co-operates closely with the various great invalidity insurance institutions who liberally support such local organisations as bid fair to prevent permanent ill-health. The State gives a yearly grant of £3,000. The working of the Central Committee presents an admirable object lesson in organisation and the avoidance of over-lapping, and the Central Bureau in Berlin is visited by interested inquirers coming from almost every European State, from English Colonies and from America. It is the arduous duty of the General

Secretary to travel throughout the Empire in an advisory capacity, and all new local schemes and associations are carefully studied by him. In his remarks on the modern combat against tuberculosis amongst children Professor Nietner stated that when the Central Committee was first established its efforts were mainly directed to the care for the still curable cases, the means for so doing being amply provided by the Invalidity Insurance Institutions. But latterly the trend has become ever stronger towards prophylaxis. It is now also realised that prevention must begin with the child. This truth was practically ignored during the earlier history of the campaign against tuberculosis in Germany, partly owing to the fact that little was definitely known about the incidence of this disease in childhood, while the latent tuberculosis of infancy was almost an unknown factor. Kirchner, in Germany, first pointed out that though the incidence of tuberculosis amongst adults is steadily decreasing in Germany, the children of the nation do not participate in this decrease.

The researches of the last ten years have brought to light facts that point to the conclusion that in a very large majority of cases infection occurs during childhood, and, indeed, in the first years of life. Hamburger declares that 90 per cent. of all children up to the completed 12th year are infected. Schlossman has gone so far as to say that tuberculosis is a true children's disease, is acquired during childhood and most be prevented, treated and healed during childhood. The fact stands beyond a doubt that in by far the greater number of cases the source of infection can be traced to the human subject suffering from "open" tuberculosis and that infection is acquired through the close intercourse resulting from family life within the walls of the home. Only those preventive measures can, therefore, hope for success which take this fact consistently into account. But to prevent the child from becoming infected in his own home environment without weakening those family ties and responsibilities which are so essential to the moral health and true happiness of the nation offers a social problem of the utmost complexity. Professor Nietner himself deprecates drastic schemes for completely separating the child from his family, though every care should be taken to safeguard it in its own home. Professor Nietner denied that tuberculosis was a "school disease," and maintained that the school could not justly be held responsible for the spread of infection. He attaches the utmost importance to the careful organisation of the school medical service in the battle against tuberculosis, and said that to the school doctor alone was the power given to prevent latent tuberculosis developing into active disease in the children examined by him and kept under his watchful supervision. He said that with a complete State organisation of school medical supervision the discovery and recovery should be possible of a large number of children who might otherwise become later on a serious strain on the economic resources of the national through developing active tuberculosis during the wage-earning period of life. Germany can boast of a very large number of agencies for promoting the health and welfare of children, and these are closely linked with the school medical service. In the sanatoria for children the practice of imparting some school teaching is rapidly gaining ground. Finally, Professor Nietner attached great value to the use of tuberculin in the treatment of tuberculous children and claims good results from it if properly administered.

(a) Abstract of Inaugural address delivered before the New Medical School of the Royal Hospital for diseases of the Chest, City Road, London, E.

OPERATING THEATRES.

WEST LONDON HOSPITAL.

ABDOMINO-PERINEAL EXCISION OF THE RECTUM FOR CARCINOMA.—MR. ASLETT BALDWIN operated on a man, *æt.* 60, who had been admitted for carcinoma of the rectum, which could be felt above the sphincters. There was a history of the passage of mucus and blood for a considerable time. The patient complained very much of diarrhœa, which was much worse in the morning; many times it was mainly mucus that was passed.

After the skin over the abdomen had been sterilised by washing with acetone and painting with tincture of iodine some hours before the operation, the iodine being also painted on immediately before the operation, an incision was made over the middle of the left rectus muscle at its lower end, the sheath was opened, the muscle displaced outwards, and the abdomen opened. The hand was introduced, when it was found that the growth extended higher up than had been ascertained by examination from below, but it was quite movable. Some glands in the hollow of the sacrum were enlarged, but the liver appeared to be free from growth. The patient was now placed in the Trendelenburg position, and the centre of the sigmoid loop then drawn out of the abdomen; intestinal clamps were applied after the intestines had been carefully packed round with gauze, and the bowel and mesentery were divided between the clamps. The divided ends were wiped with swabs and painted over with pure carbolic. The two ends were then completely closed by two layers of continuous sutures; the first suture passed through all the coats, this being buried by a second suture passing through the peritoneal and muscular coats. Another incision was now made through the skin about two inches internal to the left anterior superior spine, the muscles were split in the direction of their fibres, the transversalis fascia was divided, and the peritoneum again opened. The upper closed end of the sigmoid was passed out through this opening and sutured into position to form a permanent colostomy; but the bowel was not opened. The small intestines were now drawn up from the pelvis, packed into the upper part of the abdomen and kept there by an abdominal cloth held in position by an assistant. An incision was next made with scissors through the peritoneum on each side of the bowel to be removed extending downwards to the bottom of the pelvis. The lower ends of these incisions were joined by one which passed between the rectum and bladder, for which very long scissors had to be used. The mesentery opposite the divided bowel was then cut through with scissors, and the superior hæmorrhoidal artery ligatured. The bowel below this and its mesentery and the tissues between the bowel and the sacrum were now peeled down as far as the lower part of the pelvis, thus taking bowel and enlarged glands, etc., down in one piece, which was then pushed to the bottom of the pelvis. The divided peritoneum was next brought together from below upwards by a continuous suture of iodine formaline catgut made to resist absorption in muscle for three weeks; thus the lower part of the peritoneum was closed above the bowel to be removed. The abdominal cloth was then removed and the abdomen closed in layers.

The patient was turned into the left lateral position. The anus was painted over with pure carbolic acid, and was completely closed with a continuous thread suture. Incisions were made round the anus and the gut separated in front and at the sides, and after working up a short distance posteriorly the bowel was found to be completely free and was removed. The deeper parts of the wound were brought together as much as possible with buried iodine catgut sutures. The skin was closed with silkworm gut sutures, excepting where the drainage tube was inserted.

During the whole of the operation saline solution was run into each side of the chest by means of two large hollow needles.

Mr. Baldwin said he had preferred to displace the rectus muscle outwards in opening the abdomen

because this method did not interfere with its nerve supply, nor was there risk of injuring the deep epigastric vessels. Some people, he remarked, advocated the operation he had just performed in every case of carcinoma of the rectum, and no doubt in many cases he thought it gave the best prospect of permanent cure; but whenever possible and safe he always aimed at preserving the normal anus, for a colostomy is to some persons a great nuisance. The ideal operation, he considered, was to bring healthy bowel down through the sphincters and attach it to the skin after having removed the mucous lining of the sphincters. When this is not possible, an end-to-end anastomosis may be done several inches above the sphincters after the coccyx has been removed and, if necessary, the lower part of the sacrum. The disadvantage of this is that the posterior sutures very often give way, and a fæcal fistula results, but this in time usually closes without further trouble; also some degree of stricture sometimes results at the site of anastomosis, which may require dilatation with bougies for a time. The objection to making the artificial anus at the upper end of the sacral incision is that the fæces are often projected backwards instead of downwards, and the situation of the artificial anus is difficult for the patient to attend to conveniently, but it has this advantage, that sometimes the upper bowel subsequently prolapses to a certain extent, and it may be possible later on, by a second operation, to join it after this has occurred to the lower end, provided sufficient has been left, and thus restore the continuity of the bowel and bring the normal anus into use again. The reason why none of these methods were adopted in this instance was that the growth was too near the sphincters to make it safe to leave them, and a posterior anus without sphincters is much less under control than one in the inguinal region.

If the patient remained comfortable the colostomy would not be opened for about three days, so as to get the abdominal incision partly healed before there is any chance of contamination.

All the wounds healed by first intention, except where the drainage tube was inserted below, which was removed several days afterwards, and the patient made an uninterrupted recovery.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD FRIDAY, OCTOBER 25TH, 1912.

The President, Mr. A. H. TUBBY, in the Chair.

DR. E. C. WILLIAMS read a paper on precocious development in a boy, *æt.* 6. The patient was unusually tall and heavy for his years, and his external genitals were fully developed. He was slow in movement and intellect. There was an abundance of pubic hair, but none in the axilla. His voice was deep like an adult. He was in excellent general health and could lift with ease heavy weights. No abdominal tumour could be felt.

DR. EDMUND CAUTLEY showed (1) a case of tetanoid spasms. Male child, born September 4th at term, without difficulty, and brought up on milk and barley water. Since 10 days of age he had had attacks of rigidity about every half hour. The mouth was said to be clenched, the neck rigid, but the head not retracted, and the hands clenched. He took food with difficulty and regurgitated some through the nose during the attacks. The child's nutrition was good. There was no indication of sepsis, and only a few curds were present in the stools. During the attacks the whole of the upper half of the body became rigid, the neck muscles extremely so, and the head was slightly retracted. The eyes were closed and the mouth could be opened very little. The fontanelle did not bulge. The hands were flexed at the wrists

and the fingers and thumbs hyperextended, not assuming the attitude characteristic of tetany. The toes were hyperextended. Since admission the attacks had become less frequent and less severe.

(2) A case of partial aphasia in a female child of 3, admitted to the Belgrave Hospital for Children on July 29th, 1912. For 12 days she had had slight cough, and for 6 days drowsiness and anorexia. On July 28th there was general twitching, possibly a fit. On admission she was drowsy and uttered occasional cries. There was no fever. The pupils were dilated and sluggish, and there was slight convergent squint. The head was a little retracted and the neck muscles rather stiff. The legs were flexed at the hips and knees, and the child resented them being straightened. She afterwards developed flaccid paralysis of the legs. Knee-jerks normal. Plantar reflex extensor on the left, flexor on the right side. Cerebro-spinal fluid was under considerable pressure, clear, and contained very few cells. On August 26th, she took more notice and moved arms about, but could not speak. She had steadily improved and gained weight, but spoke in a somewhat drawing manner. She was quite intelligent. The diagnosis lay between encephalitis and serous apoplexy.

Dr. J. PORTER PARKINSON showed a case of congenital syphilis (hæmaturia). The patient was a girl, æt. 8. There were seven other children; the first was born dead, the second was a seventh-month child and lived seven hours, the third child suffered from epileptic fits, and the others were presumably healthy. Three weeks before admission the patient had jaundice, vomiting and diarrhoea, and the urine was red in colour, and there was some swelling of the face and limbs. This passed off, but reappeared, and the child was brought to the hospital a week later. On admission there was slight œdema of the eyelids and ankles. The heart, lungs and abdomen were normal. The blood-pressure was 115 mm. The urine was reduced in quantity, 8 to 10 oz. daily, specific gravity, 1020, a considerable quantity of blood and a small amount of albumin. Microscopically no casts were seen, only blood cells and a few epithelial cells. There was a small linear scar on the lower lip. The Wassermann reaction was strongly positive, on this account she was having mercurial inunction. The blood in the urine rapidly diminished, and neither blood nor albumin were present after first week in hospital. The cerebro-spinal fluid was negative to the Wassermann test. The case was shown to elicit the opinion of members of the section as to the cause of the hæmaturia, whether syphilitic or not.

Dr. F. J. POYNTON showed a case of congenital family cholæmia, with some further investigations into the nature of the condition. A girl, æt. 8, was admitted for an exacerbation of jaundice from which she had suffered since birth. Father and one sister jaundiced also. One sister died at 4 months with jaundice and convulsions. Skin, conjunctivæ, and mucous membranes definitely bile-tinged. Motions normal in colour; urine occasionally contained urobilin, but never bile pigment. Spleen palpable; had been getting much smaller during stay in hospital. Blood serum free from urobilin or bile pigments. Wassermann test negative. Red cells (September 28th), 3,711,250; white cells, 11,200; hæmoglobin, 56 per cent.; colour index, 0.75. Percentage of "hematies granuleuses" in red cells, 8 per cent. (September 26th); 11 per cent. (October 4th). Fragility on four separate occasions, 0.6, 0.65, 0.65, 0.65.

Dr. C. R. BOX showed a similar case, for which excision of the spleen had been done with temporary benefit. (This patient has died since.)

Mr. P. MAYNARD HEATH showed a case of genu valgum due to rarefaction and deformity of the shaft of the femur in a girl, æt. 5½. The chief deformity was due to a sharp bend in the shaft of the right femur—about 4 in. above its lower extremity. An X-ray photograph showed that at this joint the bone was so rarefied as to be practically translucent. The rarefied area was not sharply outlined, and there was no evidence of cyst formation. There was some

laxity of the ligaments in the right knee, and a well-developed Macewen's spine at the point of attachment of the internal lateral ligament to the tibia.

Dr. REGINALD MILLER showed a case of cerebral maldevelopment (? sclerosis), with infantilism and idiocy. Boy, æt. 8½; born at full term by instrumental labour; first child. Appeared normal at birth, but did not develop properly; grasped nothing in fingers until 3½ years old. Teeth erupted from twelfth month to third year, but rapidly decayed and most were extracted when 4 years old. Height 35 in. weight 22½ lb., circumference of head 17½ in. Face senile in appearance from falling in of mouth. Testicles partially undescended, left small. Could not walk or talk; never cried. Feet inclined to cross, hands and fingers hyperextended; tremor of lips and hands. Dirty in habits, very destructive. By retching efforts brought food up into mouth, and unless controlled produced vomiting by forcing fingers down his throat. Wassermann test, negative. Skiagrams (Dr. Harrison Orton): Long bones small, but otherwise normal. Mandible small and senile in type; only five teeth of second dentition visible unerupted.

Mr. DUNCAN C. L. FITZWILLIAMS showed a case of coxa vara in a boy, æt. 7. The condition was extremely like a congenital dislocation of the hip, for the whole of the right limb was smaller than the left; this was especially well seen in the feet.

Mr. T. H. KELLOCK showed a case of traumatic pancreatic cyst after operation. The patient, a girl, æt. 11, was knocked down by a horse in March, 1912, and said she was kicked by the horse in the abdomen. She was admitted to hospital almost immediately afterwards, somewhat collapsed and complaining of pain and tenderness in the left hypochondrium. The muscles in that region were very rigid, and it was thought that there was some fulness in the region of the spleen; there were no external marks of injury. The case was taken to be one of slight rupture of the spleen. Nothing was done surgically, the child gradually improved, and was sent to a convalescent home about a fortnight later. She was re-admitted to hospital September 14th, 1912, apparently in perfectly good health, a tumour was visible as she lay on her back or stood up, occupying the left hypochondrium; it was tense, fluctuating, fixed, and not tender on manipulation; extended to the right beyond the middle line of the body; was resonant above, but quite dull on percussion; at its central part resonance could be obtained behind it in the left lumbar region. The temperature was normal, and there were no abnormal constituents in the urine.

A few days after admission the abdomen was opened, and a retroperitoneal cyst exposed, which proved to be pancreatic. This was opened and drained. The patient was discharged on October 8th.

Mr. SYDNEY STEPHENSON showed a case of ocular torticollis in a girl, æt. 9, who was brought to the Eye Department of the Queen's Hospital for Children on August 29th, 1912, with the history that she had been treated for some months by electricity for torticollis. The child had carried her head on one side since she was 12 months of age, and the condition had not become worse since then. She had had no illness other than measles at 2 years of age. In the child's habitual attitude the head was inclined towards the right shoulder, forming an angle of about 30 deg. with the vertical. It could be straightened instantly at the child's will. There was no tension on the sternomastoid muscle, no twisting of the head and no asymmetry of the face, points in which the condition offered an instructive contrast with cases of ordinary torticollis. There was no obvious deformity of the skull. The spinal column was slightly inclined to the right in the dorsal region, and to the left in the lumbar region. With the head in the abnormal position, the right eye was often free from squint, but at other times it was inclined downwards for from 8 deg. to 10 deg. (strabismus deorsum vergens). But as soon as the head was straightened the other (left) eye deviated upwards to a corresponding amount (strabismus sursum vergens).

Mr. PHILIP TURNER showed a case of lateral sinus thrombosis; operation; recovery. Boy, æt. 14, was admitted on July 8th for headache and discharge from the left ear. This discharge from the ear had been present for eight years, and had appeared during an attack of typhoid fever. The acute trouble appeared about a week before admission after a visit to a swimming bath. The left side of his neck became stiff and painful, and he had a shivering fit. On admission, his temperature was 104 deg. Fahr., and pulse-rate 128. A diagnosis of lateral sinus thrombosis was made. The antrum and mastoid cells, when opened, contained pus, and the posterior wall of the antrum was found to be destroyed, exposing the posterior fossa. A radical mastoid operation was rapidly performed, and the posterior fossa thoroughly exposed. The wall of the lateral sinus was sloughing and pus was oozing from a small perforation in this. The sinus was opened for an inch, and, after septic clot had been scraped away, bled freely from its upper end. The internal jugular was then ligatured. The temperature fell to normal 23 days after the operation, from which time convalescence was uneventful. Cultivations of the pus showed the presence of *Bacillus pyocyaneus*, *pneumococcus*, and *Streptococcus longus*.

Dr. T. R. WHIPHAM showed a case of (?) anterior poliomyelitis. The patient was a girl, æt. 7, who presented an atrophy of the muscles of the forearms especially on the left side. The wasting was more marked in the flexors than in the extensors. The hands were small, and there was marked wasting of the muscles of the thenar and hypothenar eminences. The interossei were also affected. The reflexes and sensation to all stimuli were normal. The upper arms were unaffected, and there was no abnormality elsewhere. The condition was first noticed when the child was 3 months old, and did not seem to have progressed since.

SPECIMENS.

Dr. ALEXANDER MORISON showed a specimen of deficient foramen ovale septum in a male infant, æt. 5 months, who was admitted to the Great Northern Central Hospital on April 29th, 1912, suffering from difficulty of breathing, with signs of bronchitis and a systolic cardiac bruit. Bruit apical, loudest on left posteriorly. Also exhibited cantering rhythm at apex. Condition regarded as cardiac malformation. No cyanosis. Pulse-rate 132; rhythm regular. Respiration 32 to 38. Temperature normal. Death occurred on May 29th, 1912. At the autopsy all the chambers of the heart were enlarged and hypertrophied; this most marked in right auricle, which exhibited the somewhat rare abnormality of deficient septum, as distinguished from patent foramen ovale.

Dr. EDMUND CAUTLEY exhibited a specimen of tuberculous right kidney from a child, æt. 12 months, who during life presented a large, soft, tense, elastic tumour in the right lumbar region, extending down as far as the anterior superior iliac spine, and pushing the liver forward and to the left. No pus or tubercle bacilli were found in a catheter specimen of the urine, and von Pirquet's reaction proved negative. The tumour increased rapidly in size and presented a soft fluctuating swelling over the end of the last rib. An incision was made in this region and about 14 oz. of sweet, sterile pus evacuated. Death ensued a few days later from asthenia. The temperature was irregularly febrile throughout. *Post mortem*, the right kidney was much enlarged and the upper half extensively caseous. It communicated with the remains of a post-nephritic abscess cavity.

SPECIAL REPORTS.

FESTIVAL DINNER OF THE IRISH MEDICAL SCHOOLS AND GRADUATES' ASSOCIATION.

The annual festival dinner of the Irish Medical Schools and Graduates' Association was held on Thursday, October 31st, at the Hotel Cecil. The President, Dr. H. Macnaughton-Jones, was in the

chair, and a large and distinguished gathering, including many ladies, was present. After the usual loyal toasts had been honoured, Dr. W. Douglas, the President-elect, proposed the health of "Our Defenders," and Surgeon-General Greany, T.M.S., replied. The toast of "Our Guests" was proposed by Sir R. Havelock Charles in a felicitous and witty speech, coupled with the names of Sir James Barr, the President of the British Medical Association, and of Dr. Esmonde, M.P. Sir James Barr said that, although by birth an Irishman, he did not possess an Irish qualification. In company with some of the earlier reformers, including Sir Walter Foster, for many years past he had taken a large interest in medical politics, and especially in the one-portal system. Hence he had been led to take exception to the action of the English Royal Colleges of Physicians and Surgeons, and of various official and other bodies, whereby many hospital appointments were open only to those who held the qualifications of these examining bodies. Nowadays he imagined that the necessity for a one-portal system was gradually disappearing, owing to the multiplication of universities, and in the process of time this particular abuse of which he spoke would die a natural death. So far as the Insurance Act is concerned, Sir James Barr said that he was sick of the whole business. He regarded the Act as a wretched makeshift, and remarked that all that he had said in times gone by was not half strong enough. During the whole of the day on which he was speaking he had been busily engaged in discussing the Act, and for all he knew his colleagues might even then still be sitting. There was not a day in the week on which some member of the general public did not say to him, "Why does not your profession wreck the Act?" His reply was, "Why not wreck it yourselves?" His only personal concern in the matter was in paying their own private contributions. He sincerely hoped that whatever decision was arrived at would be accepted by the profession as a whole. He could not help saying to himself, "Here is an Act of Parliament which will cost the nation £30,000,000 a year. What is the public going to get for it?" If taken ill, a man may get 10s. a week, a woman 7s. 6d., after four days' illness, and on production of a medical certificate to prove that there has been no shamming. As for the maternity benefit of 30s., he regarded it as a miserable dole, which was not likely to stop the falling birth-rate. They were promised an efficient medical service, but what they would get was no more like an efficient medical service than a London fog was like bright sunshine. The service contemplated was the worst possible medical service that could be given. In his opinion the more one does for the wage-earning portion of the community, the better for the nation at large. After careful perusal of the Act, the only definite benefit that Sir James Barr could discover was the death certificate. He never had justified club practice, which he regarded as the greatest curse of the medical profession. It was usually begun by young men who wished to begin practice, and so get into touch with the public. On the part of others, it was an act of charity, but it was quite a different thing to be compelled to do work on such terms for the Government. (Applause.) As far as he could see, the Act was to be worked on a charitable basis, since it was only by linking up with charitable institutions, such as hospitals and dispensaries, that treatment could be carried out. Apart from the problematical sanatorium benefits, there is no direct provision as yet. At the present time kite-flying is being carried on, calculated to arouse the ire of the medical profession. To start with, we were threatened with 5,000 underpaid German doctors, who were to be brought over to work the Act. A public medical service had now been proposed, but this, although not inadvisable, would be enormously expensive, and once established, a hospital service would also have to be set on foot for those insured, so that for 15,000,000 people the cost would not work out to less than £1 per head. On this salary basis men would not work more than five, six or eight hours a day, instead of sixteen or eighteen. The Insurance Commissioners had already threatened to

start a medical service with a certain section of the profession, who would inevitably be the riff-raff, and would be ostracised by their brethren. Under any circumstances, Mr. Lloyd George would not get the best men to work his scheme. In thanking those present for the cordial reception which they had accorded to himself and his wife, Sir James Barr said that he was most anxious to do the best he could for the medical profession, and for the profession to do the best they could for themselves, not merely as a matter of remuneration, but for the honour and dignity of the profession. It was well known that wherever a medical man sees suffering he tries to relieve it, and, whatever might happen, the public at large might rest satisfied that their interests are perfectly safe in the hands of the doctors.

Dr. Esmonde, M.P., said that at the beginning of the Insurance Act dispute the Chancellor of the Exchequer had offered the sum that no honest or self-respecting man could entertain. Personally, he was sorry that in the beginning the Chancellor did not come to two or three *bona-fide* general practitioners who could have told him facts. The Chancellor had never treated the profession as a great and honourable one which had done more than any other for the public welfare. Dr. Esmonde said that each medical man would, however, be taking a grave responsibility if he did not very carefully consider whether the terms now offered should be refused or accepted as a basis of settlement of the question. Previously club practice had been done for small remuneration, but the class of work now required was far different, and the medical men must see that the best possible service should be given. The State service with which they were threatened is an impossibility, but an endeavour might be made by means of local metropolitan services to break down the strong present opinion of the profession. His view was that we ought to make an effort to treat with the Chancellor of the Exchequer. On both sides some concessions would probably have to be made. The secrets of the patients were, however, theirs, and they did not intend to have any third party intervening. It is all very well for the well-to-do members of the profession to talk about holding out, but in so doing they must avoid injury to their poorer brethren. He knew from experience of 25 years' general practice the difficulty of finding rent for the quarter-day. He thought that the time had now arrived when, in the interests of the general practitioners some settlement should be made. If after trial for some months it fails, then it will be time to say that the profession will have nothing to do with it.

The toast of "The Association" was proposed by Sir Frederic Champneys, President of the Royal College of Physicians, and responded to by the President, Dr. Macnaughton-Jones, who said that he regarded the Insurance Act as the "great betrayal." He never thought to live to see his profession so grossly misrepresented since the beginning of discussion upon the Insurance Act. Even at the last moment the Chancellor appears to be trying to place the profession in the light of the servant who applied to his Irish employer for an increase of wages, and to whom the employer replied, "By aisy stages I'll raise your wages from fifty shillings to two pounds ten."

The toast of "The President" was drunk with acclamation, and the proceedings then terminated.

THE HEALTH OF THE BUSINESS MAN. (a)

A CONFERENCE on "The Health of the City Worker," under the auspices of the Incorporated Institute of Hygiene, was opened last week at the Guildhall by the Lord Mayor of London. The Lord Mayor (Sir Thomas Crosby, M.D.), who opened the proceedings, said that he believed that the principles which applied to the health of the City worker would apply equally to all private houses. During his 60 years' practice of medicine in the City he had seen an almost entire rebuilding of rooms in which clerks worked. It was

(a) Institute of Hygiene. Conference on "The Health of the City Worker," Guildhall, London, October 28th, 1912, Sir William Bennett, K.C.V.O., F.R.C.S., President, in the Chair,

his experience that the health of the clerk was well looked after, but it was well that with improved ideas the subject should be ventilated. Referring to the drainage of the City, he said the improvement had been marvellous and the health of the workers had seen a corresponding change for the better. Many fevers had disappeared from the City. In his youth typhus was no uncommon thing; now it was unknown in London. With improved water supply enteric fever was very rare. These were only passing thoughts of a wide and long experience. He bade the delegates welcome on behalf of the City of London and of himself. He looked forward with great delight to receiving instruction from the speakers.

Sir William Bennett said:—The Incorporated Institute of Hygiene, as may be known to some of those present, is more particularly concerned in the practice and teaching of the health of the individual and the hygiene of the home—personal and domestic hygiene—and particularly in the attainment of purity of foods. It therefore seemed to the Council that the health of the business man and City worker came well within the sphere of its operations, and was at the same time a matter of rapidly increasing importance in these days of high pressure and acute competition. It is obvious that work—in quality as well as quantity—of those in indifferent health, whether physically or mentally, must be of comparatively small value, and, further, that a temporary depression of vitality or energy in a worker, generally in good health, may seriously impair or annul the value of work for the time being. It is also, I suppose, an open secret that the surroundings and individual habits of many of those who carry on their affairs in our cities and towns are not such as tend to the highest grade of efficiency. It was therefore determined to promote a conference upon the subject of "The Health of the City Worker," with a view to discussing the matter and in the hope of arriving at some useful conclusions and suggestions. The time for such a project in the City of London seems particularly appropriate, too, seeing that the present Lord Mayor has not only been a hard worker in the City for many years, but that he is, in addition, a well-known medical man. He was, therefore, approached upon the matter, and not only expressed a sympathetic interest in it, but consented to open the Conference himself, thus giving it an importance—especially in the minds of City men—which it could not otherwise have obtained. Such is the story of the materialisation of the work which commences this afternoon. In concluding these remarks, I cannot help feeling that behind the interest we take in the matters about to be discussed, there exists in the minds of all of us the hope that the Lord Mayor will tell us the secret which has enabled him, after having passed by a full decade the traditional span of three score years and ten—after having, in fact, advanced well into middle age—to retain the vitality, energy and mental acuteness of a youth of thirty.

Dr. Olsen, speaking on the business man's lunch, said that the business man was naturally a brain, and not a muscle worker. Men like Lord Strathcona, in order to avoid hurry at meals, had adopted the habit of taking only two meals a day. But the luncheon hour is a safety valve. A light lunch is preferable. Meat should be cut out of the lunch, and a poached egg on toast, milk and bread, followed by fruit or nuts, was advisable. Nuts were sometimes found indigestible by people, but this is because they failed to masticate them properly.

Dr. Cameron Gillies said one of the things that appeared to him was that the rush and worry of City life was a fruitful source of dyspepsia. One could recognise this every morning in the City of London, where the chemists' shops at the various stations were crowded by customers. This was not due, he had found, to the "night before," but to the highly strung nerves of many of the workers; in the neighbourhood of the Stock Exchange the same thing was observable. He had known business people suffering terrible agonies from this source of trouble, and he would like to hear on this question some words of guidance. He

had no intention of saying anything on the subject himself.

Dr. Farquhar Buzzard said that he would define the business man as one whose business it was to keep fit. His success depended on keeping his brain and nerves in the best condition. He had nothing to do with the business man in the City, and would therefore confine himself to the business man when his health failed. Why does a business man lose his health before the age at which he might be expected to fail? There were certain fallacies on this subject in the public mind. He did not believe that mere rush and a sedentary life were mainly responsible for ill health. Hereditary causes were fruitful of such an evil, and men so troubled should not have chosen the business life. Others started with a normal reserve of power, but took no heed of their health and broke down before they reached 40. Another group of cases were the bad habit cases; they were all familiar with the fact that over-drinking, over-smoking, and over-eating were bad habits. He himself smoked and drank. There was a fallacy, he was convinced, in the public mind on the subject of drink. The medical profession were responsible for this fallacy very largely. There were men who confined themselves to whisky by medical advice and did themselves infinite harm. He felt that it was not important to confine oneself to any particular food, but it is important to rise with an appetite. As to exercise, he had patients who complained that they could not afford time for exercise. He had found cases of neurasthenia which were entirely due, however, to men trying to overcome by exercise the loss of energy incurred through work, thus draining the body of energy by two exists. He did not believe in muscular exercise, but he did believe in recreation.

Mr. Lewis R. Tomalin said that generally he followed the advice "early to bed and early to rise and never get drunk." Since 1881, when he was 32 years of age, he had been a teetotaler, while he had never been a drinker, and he had made a habit of wearing wool and even sleeping in blankets.

Dr. Cahill asked for some advice on exercise. Should they play golf or put their money on horses? City men had no monopoly of neurasthenia or the effects of over-feeding. The business man was, on the average, healthy as compared to men in other classes of workers. His life was, he believed, just as long. It was an easy life compared with men in other occupations. Their hours were short, they had time for "Bridge" at the Club before getting home for dinner, and they did not go to the office before about 10.30.

Dr. Strickland Goodall, dealing with diet in business, said that the City man oscillated between times of starvation and times when he did himself very well. To a man engaged strenuously in business the chief meals should be breakfast and the evening meal. Midday meals and all forms of games and business discussions should be avoided, because an organ in activity needed more blood supply than an organ at rest. He was opposed to feeding in tabloid form, and he believed in ceremony over meals. At least an hour should be devoted to each meal; avoid fads in food, and exhibit moderation in all things dietetic; pay a periodical visit to the dentist; the chief meals of the day should be the morning and evening meals; avoid all business discussions and reading during meals.

Sir Richard Stapley said that business men to-day indulged less in drinks between meals, and this was one of the great causes of improvement in the health of City men. Twenty-five years ago his firm took a stand against forcing drink on customers, and now their policy had been entirely successful. In the City now there was less enticement to these bad habits, both on the road and in the houses. It did not matter so much what people ate or what they drank, but what did matter was how they ate and how they drank. A friend of his believed in eating wholesome food in the fresh air. The facilities for this were much greater now than twenty years ago. We could all build up our own health by proper thought.

Dr. Lauzen-Brown said that, in addition to improvement in the water and food supply, they could pride

themselves in the City on having laid on a better supply of fresh air. This had led to a great diminution of the dread scourge of tuberculosis. He is informed that at the present time there were not more than thirty cases of tuberculosis in the City. The habit of avoiding alcohol between meals was spreading from the upper strata of society to the lower.

The Chairman, in his closing remarks, said that for those who did not work in the City it was hard to speak of City habits, but they had learned much that was valuable from the discussion. Several points of great interest had been mentioned. On the question of exercise he believed more nonsense had been talked than on any other subject. Personally, he took as little exercise as possible. Some time ago, when his health was not so good, he was advised to ride before breakfast, and he did so for a month, but if he had not abandoned the practice he was convinced he would not be here now. No general advice could be given, but a law could be laid down only in special cases. A tired man should not tire himself further with exercise. Drinking between meals was the most vicious thing in the world. For twenty-seven years he had taken a good breakfast and a light milk pudding for lunch, and ever since, with two slight exceptions, he had not had a day's illness.

THREE SANITARY REPORTS. (a)

THESE three reports by the Medical Officers of Health of the respective districts all have certain features in common. Each shows an increased death-rate over that of the previous year. England had to pay toll for a meteorologically perfect summer by suffering an epidemic of infantile diarrhoea. The prevention of tuberculosis occupies the attention of all the sanitary authorities, and importance is attached to diseases of childhood, notably measles and whooping-cough, which are popularly supposed to be inevitable in their incidence and harmless in their effects. The Carlisle authority issues a careful notice giving precautions against the spread of these diseases. Derby is especially unfortunate in its diphtheria statistics, the five-year period 1907-1911 showing the highest recorded prevalence.

Dr. Bate notes that Bethnal Green, in common with the rest of London, is becoming depopulated centrifugally. Here, too, the infantile death-rate from diarrhoeal diseases was considerable, and amounted to 44.8 per 1,000 births, nearly treble that of 1910.

These three reports are well got up and furnished with an abundant supply of statistical tables and diagrams, and each contains material of value to those who are directly concerned with matters pertaining to the public health.

FRANCE.

Paris, Nov. 2nd, 1912.

LUMBAR PUNCTURE IN SURGERY.

LUMBAR puncture, says Dr. Mauclair, of the Hôpital de la Charité, as reported by the *Monde Médical*, is a comparatively recent operation; it was first proposed by Leveard Corning, of New York, in 1885.

But it was only in 1891 that Quinke showed all its advantages from a therapeutic point of view. At first it was almost exclusively the Germans and the Americans who employed the lumbar puncture, but soon afterwards, Tuffier drew attention to the special

"Annual Report of the Medical Officer of Health of the County Borough of Derby for the Year 1911." By Albert E. Brindley, M.D., D.P.H., etc. J. W. Simpson and Sons, Ltd., Derby. 3. "Report on the Sanitary Condition and Vital Statistics of the Metropolitan Borough of Bethnal Green during the Year 1911." By George Paddock Bate, M.D., Medical Officer of Health, etc. Thos. Bean and Son, 67, Golden Lane, E.C.

characters of the cephalo-rachidian liquid in traumatism of the skull and the vertebral column, consisting, in a series of communications on the subject, on its sanguinolent coloration in fracture of the skull, and these observations were confirmed by Guinard, Poirier, Schwarz, Monclaire and others.

By the lumbar puncture a certain quantity of cephalo-rachidian liquid is withdrawn from the sub-arachnoid space; the needle is inserted between the fourth and fifth vertebræ, not exactly in the median line, but about a quarter of an inch to the right so as to avoid passing through the thick interspinous ligament; the needle is directed slightly upwards and inwards. The instrument should be in platinum, strong and resisting, about five inches in length with the point short and sharp. To distinguish the blood coming from an accidental wound of a vein from that of intra-rachidian hæmorrhage, the liquid should be received into several tubes of the same calibre.

Where the liquid presents a gradually decreasing coloration, the needle has passed through a vein of the skin or the muscles; also where the puncture gives issue of blood mixed with the liquid, a vein of the dura mater has been wounded; in that case it is sufficient to push the needle in a little farther to obtain the clear liquid.

To avoid syncope, it is better that the patient should not be seated, but placed on the side with the legs well drawn up so as to expand as much as possible the inter-vertebral space. As to the quantity of liquid to be withdrawn there is no fixed rule, it depends mostly on the degree of pressure of the liquid, but an average of 5 drachms should scarcely be exceeded. Naturally, in case of hypertension where the liquid comes out in a strong jet, a larger quantity may be extracted than if it flowed slowly drop by drop. In any case, no more than one ounce should be extracted at the time, the total amount of cephalo-rachidian liquid in the normal state being but 6 ounces, it is better to repeat the operation, if necessary, than to extract too much at once.

As after effects, vertigo, syncope, etc., have been observed, but such accidents are rare; they chiefly concern nervous persons.

Headache of short duration, however, is frequently complained of, it is due to an increase of pressure of the cephalo-rachidian liquid, but this hypertension is quickly followed by hypotension.

It cannot be denied, however, that several cases of sudden death after lumbar puncture have been reported. Dr. Cramer, of Geneva, recently published a number of cases, 38 in all, but 28 of these concerned patients suffering from tumours of the brain or cerebellum. As to the real cause of such fatal accidents, the opinion has been expressed by Prof. Sicard that the lumbar puncture by diminishing the quantity of the cephalo-rachidian liquid causes to fall on the floor of the 4th ventricle the mass of cerebellum increased by the volume of a tumour, thus producing compression of the respiratory centre.

These accidents, however rare, call for prudence in the practice of the operation, hence the necessity of allowing the liquid to flow only drop by drop.

Indications and results.—In cases of cerebral commotion, slight or grave, the lumbar puncture gives but little result.

In cerebral contusion attended with hæmorrhage on the surface of the brain, the operation may be useful as a decompressor of the nerve centres; the liquid is coloured.

The third variety of traumatism of the skull is cerebral compression and generally due to effusion of blood (rupture of the middle meningeal artery) on the brain. The effusion takes place between the inner table of the skull and the dura mater.

The signs of cerebral compression from effusion of blood are loss of consciousness, hemiplegia on the opposite side and aphasia, if the centre of language is touched.

Here the lumbar puncture possesses real therapeutic value: the cephalo-rachidian liquid, abundant and hæmorrhagic, flows out under strong pressure and the operation frequently improves the condition of these patients.

Fractures of the skull are sometimes difficult to diagnose, as none of the signs can be regarded as conclusive. Subconjunctival ecchymosis has but little value if it does not appear within 36 or 48 hours after the traumatism. Otorrhagia, epistaxis, may easily mislead, and the cephalo-rachidian liquid flowing through the nose or the ear, may pass unperceived, being mixed with blood.

Hence, it was asked if there did not exist a more certain sign affirming the existence of these fractures and some authors believed to have discovered it in the hæmorrhagic transformation of the cephalo-rachidian liquid withdrawn by the lumbar puncture. But repeated experiments showed that even in positive fractures of the skull the liquid may come out clear.

From a therapeutic point of view, puncture has given good results in cases of persistent headache following traumatism.

Other affections have also been benefited by this treatment although to a lesser degree. It is thus that in certain cases of meningitis, cerebral abscess, tumours of the encephalus, especially those accompanied with marked hyperpressure of the cephalo-rachidian liquid, provoking amaurosis, the lumbar puncture produces frequent improvement, but this method is specially useful in clearing up a doubtful diagnosis, for instance, to distinguish a tumour from a syphilitic gummy.

Good effects of the lumbar puncture have also been remarked in certain ocular lesions with tendency to glaucoma and in cases of uramic cephalalgia.

However, it must be admitted that lumbar puncture produces but transitory relief, as the liquid reforms with a certain rapidity.

On the other hand, it is of great use in clearing up the diagnosis of fracture or dislocation of the vertebral column, where the liquid is rose-coloured or bloody the fracture is evident.

GERMANY.

Berlin, Nov. 2nd, 1912.

At the meeting of the Naturforscher and Aerzte in the Department for Surgery, Hr. Czerny, Heidelberg, in connection with a paper on the

NON-OPERATIVE TREATMENT OF TUMOURS

showed a large series of interesting illustrations of cases that had at one time appeared to be perfectly hopeless. They were mostly relapsing cases in which the disease had reappeared several times. The treatment had been by various combinations and aids, with a sort of recovery in the end, in which the patient at last secured a more or less tolerable state of existence.

1. The first case was one of recurring sarcoma of the upper jaw, in which recovery had been brought about by scraping out followed by X-rays.

2. Several cases of epithelioma that had been cured by mesothorium and in which the cosmetic effect had been remarkable.

3. Large epitheliomata in which recovery had been brought about by fulguration and X-ray treatment.

4. Several cases of various forms of tumour (sarcoma of the parotid, the abdominal wall) that had been extirpated by the de Forest needle (electric arc light).

5. Lupous carcinomata that had been treated with excellent cosmetic results by fulguration and X-rays.

6. Various cases (sarcoma of the cheek, carcinoma of the orbit, malignant lymphomata) in which various recurrences had been treated by salvarsan by injection sometimes into the walls of the tumour, and X-rays, had undergone striking and rapid improvement, ending in recovery.

7. Several cases of large carcinoma of the breast, which had ulcerated and had metastases in the surrounding parts, in which a combination of various forms of treatment had led to recovery.

8. Several cases of carcinoma of stomach, cardia, and rectum, in which by means of intensive Röntgen illumination in a few cases improvement took place and in others recovery.

9. Finally the animal tumour was shown in which recovery had been brought about by injection of borate of cholin. (Vide latest publications of Werner and Szecki, "Med. Klinik," 1912).

Hrn. Nobel and Hecht, Vienna, followed with a report of their

ELECTROCARDIOGRAPHIC STUDIES OF NARCOSIS.

Proceeding from the fact that chloroform had an injurious action on the function of the heart, the writers of the paper tried to study its action on animals. 22 experiments were made on various animals (rabbits, dogs and monkeys) in which the action of the drug on the heart was followed until death took place. The effects mostly observed were disturbance of transmission (through bundle of His), of various grades, more extra systole, occasionally paroxysmal tachycardia, auricular fibrillation with arrhythmia perpetua and without it, and sometimes ventricular fibrillation.

In the case of a child under chloroform the cardiogram registered no changes. Amongst the many symptoms that preceded death from chloroform, bradycardia from stimulation of the vagus was the most frequent; this was followed later by heart block or symptoms of irritation.

In the experiments on animals atropin undoubtedly did good service. It cut off the vagus and acted as a muscular stimulant to the heart. In practice it had great advantages over the usual employment of camphor or adrenalin, as camphor had to be given intravenously and adrenalin was sometimes dangerous, as Lewis and Levy had shown. Atropin was best given intravenously in doses of from 0.001 to 0.002 gm., or even before the operation was begun.

Hr. Wrede, Jena, was able, from his own investigations, to confirm what had been adduced by the two previous speakers.

Hr. Reicher asked whether the electro-cardiogram during the course of an operation would give the danger signal in time to take measures to ward off the danger?

Hr. Nobel had never observed that it would.

The Central Committee for Volks and Jugendspiele (Games) concludes an appeal to the public with the following:

1. The strength of the woman as regards the nation is as important as that of the man. For this reason bodily exercises for women are necessary.

2. In all, both higher and lower girls' schools, both in town and country, three hours per week should be given to gymnastics, and a general play afternoon should be obligatory in all grades weekly.

3. Such exercises are to be preferred as enlarge the chest and strengthen the heart; they should take place in the open air as much as possible.

4. Walks should be encouraged, also swimming, games on the ice and snow. No healthy girl should be allowed to leave school until she has learned to swim.

5. Excursions should be kept up the whole year, the obligatory play afternoon may be made use of for this purpose. In the upper classes, independent of the usual school excursions there should be at least one whole day excursion once a year. Holiday excursions should be encouraged by the school.

6. After leaving school, gymnastics, country games and allied bodily exercises should not be neglected. Every true friend of the Vaterland should co-operate earnestly with the central committee, so that games and exercises that call into play the movements necessary for the female sex may become the custom of the people, and that the dress from infancy upward should be constructed on intelligent principles.

7. The State and individual communities must make provision and give opportunity for the carrying out of these exercises. The expenses attending all this have as much importance for the nation as those justifiably devoted to the German Army.

AUSTRIA.

Vienna, Nov. 2nd, 1912.

DIABETES IN THE GRAVID STATE.

PORGES related the case of a female in the fifth lunar month who was eliminating 5 to 15 grams of sugar when fed on carbohydrates, but only 3 to 6 grams when on vegetable diet—i.e., non-carbohydrate and a régime poor in albuminoids. It not infrequently

happens that females in the pregnant state often pass large amounts of sugar that might lead the unwary astray, which may be easily checked by this simple experiment. Where there is a morbid condition present this variation does not depend on the alimentary canal, but on a lesion. Genuine glycosuria, or diabetes, has also another diagnostic sign—viz., hyperglycæmia. In this case the kidney is a mere sieve or sponge for passing the saccharine fluid through it in abnormal quantity. In alimentary glycosuria the relative quantity is only disturbed in the regulation of the saccharine elimination, which has a constant level in the normal condition. Therefore a low hyperglycæmia and one easily affected by the alimentary factor are two characteristic clinical symptoms to guide us in genuine nephritic diabetes.

DIABETES INSIPIDUS.

Steiger recorded a case of considerable importance, which he thought required careful investigation. The patient had no history of any psychical disturbance, disease about the head, nor injury to cause a real typical condition of diabetes insipidus, which he would designate idiopathic, as it was not due to weakness in the power of concentration, nor hypophysical, as there was no deepening to be observed in the sella turcica.

In connection with this idiopathic condition a very irritable state of the vegetative nerve system existed, in which atropin had the effect of allaying and reducing the flow of urine, while pilocarpin, the alkaloid, increased the flow of urine. What the origin of the disease was he would not venture to conjecture, but it was interesting to investigate.

HYPERTENSION AND GLYCÆMIA.

Nagelberg, in his clinical lecture, said he was not satisfied with the simple theory that choking up and wasting of the vessels in the kidneys, causing a rise in the blood-pressure and a greater resistance in the cardiac action, was the real cause of the great amount of sugar stored up in the blood. He believed the hypertension was more probably due to adrenalin product. The examination of the metamorphosis of sugar gave a very hypertonic condition, which led him to believe that this adrenalin caused the great increase of sugar in the blood. He found in the greater number of cases of chronic nephritis with hypertension an increase in the saccharine property, and this hyperglycæmia is still further increased by the higher tension of arterio-sclerosis. When the arterio-sclerotic shrinking is complete, notwithstanding the destruction of the organ, the amount of sugar present is almost normal.

ERROR IN THE ERYTHROCYTE RESISTANCE.

Schaeffer finds that Liebermann and Fillingner's estimation of the resistance of the red blood corpuscle has many fallacies that require to be avoided. The first in the destruction of the capillary in the hypotonic solution, which was affected by the breath, and contains carbonic acid, which acts as a hæmolytic agent. Again, the temperature of the hypotonic fluid is to be observed, as the nearer the normal condition of the body the erythrocyte has the greater resistance.

THE PATHOGENESIS OF ORTHOPTIC ALBUMINURIA.

Stiller considers that all orthoptic patients are, without exception, those of an asthenic constitution, and confines his argument to the low state and weakened organisation of the kidney. Although the illness is slight at first, being confined to the kidneys, which is probably due to nephroptosis, stenosis of the upper part of the chest, initial phthisis, or a narrow aorta with sclerosis, which soon produces the jehle lordosis, which is the real cause of orthoptic albuminuria.

UNITED STATES OF AMERICA.

Washington, Oct. 12th, 1912.

THE INTERNATIONAL CONGRESS ON HYGIENE AND DERMATOGRAPHY.

(Continued from our last week's issue.)

As was eminently fitting, the section devoted to the consideration of infant and child hygiene was the fullest and most diversified of the Congress. Another

point of interest and instruction in these days of militant suffragism was the prominent part played in this section by women. Perhaps the two best papers read were by lady physicians, one by Dr. Helen Macmurchy, of Toronto, an able, practical organiser, and an exceptionally capable exponent of her views, either as a lecturer or writer. The other paper was by Dr. Janet Lane-Clayton, of London, Dr. Eric Pritchard's right hand in the campaign for the reduction of infant mortality in Marylebone. Another paper of unusual merit was read by Dr. S. Josephine Baker, of the Department of Health, New York city. Indeed, almost as many papers were read by women, most of them physicians, as by men in this section, moreover, the papers read by women compared very favourably with those read by men. Militant suffragettes are rare in the United States and in Canada but, on the other hand, women in these countries and especially those of the medical profession are coming daily more and more to the front.

The title of Dr. Helen Macmurchy's paper was

WHAT MEDICAL INSPECTION OF SCHOOLS CAN DO FOR THE SCHOOL CHILDREN.

Referring to the mentally deficient child the author said that these pupils were the source of much difficulty to the teacher, often causing disorder in the class, etc. School medical inspectors should remove such children to special classes, for their own benefit and to the great relief of all concerned. Dr. Macmurchy laid stress on the fact that medical inspection of schools, dealing with each child personally, tended to impress on us the individuality of each child, and directed attention to his endowments of strength, special senses, etc. It was pointed out that we were always trying to deal with human beings as soldiers, lawyers, children women, Chinamen, or something less than human beings. The man or woman who was dealing with human beings as such, that is the teacher, was doing the highest kind of work.

Dr. Janet Lane-Clayton discussed the organisation of the work of infant consultation and health visitors. In the course of her paper the author said that without underrating the value of a good milk supply, experience had shown the still greater value of the direction of the general hygiene of the infant, such as could be carried out by an Infant Consultation with its staff of qualified health visitors. Such organisations actively encouraged breast-feeding, and in the case of artificially fed children the amount of milk, while the number of feeds given was regulated and over-feeding prevented; the general condition of life of the child and of the mother were also supervised, and faulty points could be quickly corrected. In England many of the milk depots had been given up, and such as were still open were now, in almost all cases, attached to Infant Consultations. A valuable paper directly bearing upon infant mortality was that of Miss Ellen C. Babbitt, New York City, dealing with

THE CARE OF THE EXPECTANT MOTHER.

Miss Babbitt drew attention to the fact that the work of caring for the expectant mother had but recently been undertaken in America. At the present time in Boston, in New York, in Baltimore, St. Louis, and in Chicago, and in many of the smaller cities, the expectant mother was being watched over. This prenatal work had been undertaken by private philanthropy. The Boston Board of Health had carried on the work so excellently begun, and soon the New York Milk Committee would have the good work it was now doing supplemented by the Child Hygiene Division of the Board of Health of New York City. In all of the cities in which prenatal work was being done it was under medical supervision, the physicians making the examinations and giving individual instructions and advice. The expectant mothers were then visited in their homes by the trained nurse who went to see that the advice was being followed and to make it possible for it to be followed. This meant the hearty co-operation between the various medical and charitable agencies.

INFANT MORTALITY AND ITS RELATION TO THE EMPLOYMENT OF MOTHERS

was also dealt with. In Great Britain most authorities, including Dr. Sykes, Health Officer of St. Pancras, London, hold that the employment of mothers has a distinctly injurious effect upon the health and mortality of the offspring. The effect would seem to be an obvious consequence, taking into consideration that when the mother is at work away from home the infant is deprived of its natural food. Breast feeding is deemed by all authorities the best mode of nourishing an infant, and therefore when this form of feeding is not obtainable the infant must suffer. However, the first paper on the subject, read by Mr. Charles H. Verrill, of Washington, stated that, as a result of investigations made by him at Fall River, Massachusetts, a factory town in which many married women are employed, such employment had little or no effect upon infant mortality. Mr. Verrill found that the high infant mortality of Fall River was only in a slight degree due to industrial employment of mothers. For 38.6 per cent. of all deaths under one year of age were due to diarrhoea, enteritis and gastritis, while among children of mothers at home the percentage was 34.6. According to Mr. Verrill the causes of the excessive infant mortality in Fall River were in short the mother's ignorance of proper feeding, of proper care, and of the simplest requirements of hygiene. To this all other causes were secondary.

On the other hand, Dr. George Reid, of Stafford, England a well-known authority, read a paper in which he expressed the most decided opinion, formulated as the outcome of wide experience, that the employment of mothers did injuriously affect infant mortality. Dr. Reid advanced proofs in support of the force of his claim.

Dr. Isabelle Thompson Smart, of New York City, read a paper entitled.

STUDIES IN THE RELATION OF PHYSICAL INABILITY AND MENTAL DEFICIENCY TO THE BODY SOCIAL.

A point greatly urged in this paper was the absolute necessity for more school clinics and more hospital clinics arranged at hours to suit the needs of the school child, instead of, as at present, during the hours of the school day. Mrs. Frederic Schoff, of Philadelphia, insisted that the co-operation of parents was essential in the promotion of child welfare. A part of the section on child hygiene to which close attention was paid was that which considered the care of children's mouths and teeth. Dr. William H. Porter, Boston, Mass., pointed out that the actual condition of children's teeth could be best studied in the public schools, and that the treatment of defective teeth in such schools, whereby unclean, inefficient mouths had been made and kept clean and efficient, had been followed by a notable increase in the general physical health of the child.

The section on

CHILD HYGIENE

provided a *raison d'être* for the reading of a large number of papers by authorities of world-wide fame, and the result has been a dissemination of knowledge on the subject which will undoubtedly do a vast amount of good. In dissecting the papers read, one would probably come to the conclusion that in some respects Europe is ahead of America with regard to practical child hygiene. For example, infant consultations, with all that they imply, are almost unknown on this continent. New York, however, has little to learn with regard to the care of infants from any city of the world—indeed, could give useful lessons to most cities. On the whole, however, considering America in its entirety, the practice of child hygiene has not progressed so far as it has in Germany and Great Britain. The chief facts to be gathered from the papers read are that so far as the working classes are concerned ignorance is at the bottom of infant mortality. In America, even among the working classes, breast-feeding is at a discount, and just so long as this state of affairs exists so long with a high infant mortality persist. Educate the mothers to feed their children

at the breast would appear to be the moral to be extracted from the papers read before the Congress.

A symposium on

POLIOMYELITIS

was probably the most important event at the Congress, both on account of the reputation of the men who took part in the discussion and of the results achieved. Among those who read papers on poliomyelitis were Dr. Francis Harbitz, of Christiania, who dealt with epidemic poliomyelitis in Norway; Dr. Netter, of Paris, who discussed its aetiology and prophylactic measures; Mr. Levaditi, of the Pasteur Institute, Paris, Dr. Karl Landsteiner, of Vienna, Dr. Simon Flexner, of the Rockefeller Institute, Dr. Paul Romer, of Hamburg, and Dr. M. Neustaeder, of New York, who discussed sanitary measures against poliomyelitis. Professor Alfred Pettersson, of Stockholm, gave the results of investigations on the modes of infection and its prevention, its symptomatology in monkeys, and the epidemic of poliomyelitis in Sweden in 1911-1912. Dr. Mark Richardson, of Boston, Mass., dealt with the disease as observed in Massachusetts 1907-1912; and lastly, Dr. M. J. Rosenau, of the Harvard Medical School, announced that he had discovered that the disease might be spread by means of a species of the stable fly.

Dr. Pettersson's paper was in effect an epitome of investigations on epidemic infantile poliomyelitis by himself, Carl Kling, Wilhelm Wernstedt, and Arnold Josefson contained in a report from the State Medical Institute of Sweden. The gist of the report was that the seat of entrance of the virus of the disease is the naso-pharynx. Dr. M. J. Rosenau stated he had discovered that the disease might be conveyed by stable flies. Although opinion in Sweden admits the possibility of indirect transmission by insects and inanimate objects, the experiments with flies by the Swedish investigators were negative. Josefson, however, produced experimental poliomyelitis with saline extracts of a handkerchief and embroidery work, which had been used by patients acutely ill, even after the material had been allowed to dry for some days before making the extract. These findings are in keeping with observations by other investigators that the virus could be found in dust, and remain active after thirty-one days in sterile milk. The deductions to be drawn from the investigations of Prof. Pettersson and colleagues would seem to be that as poliomyelitis is mainly due to direct transmission the disease should be made notifiable everywhere, and that isolation of those affected should be enforced. Further, the investigations in Sweden appear to have brought out the fact that the frequency of the virus in the intestine is largely due to the swallowing of the infected naso-pharyngeal secretion; thus it follows that prophylactic measures, as well as being directed towards the naso-pharynx should include the sterilisation of the patient's motions.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

OCCUPATIONAL DISEASES.

DR. ALEXANDER SCOTT, Certifying Factory Surgeon and Medical Referee for Industrial Diseases, delivered one of a series of lectures promoted by the Glasgow School of Social Study in the Political Economy Class Room at the University, the subject of his lecture being "Trades Diseases." The subject must appeal to their higher impulses with great force from a humanitarian point of view, and it had an economical as well as a sentimental side. The lecturer said that the two essentials in every employment were: (1) That the physical and mental powers of the worker should be strong enough to enable him to perform his allotted task without danger, and (2) that the nature of his work should not affect his health or well-being. Industrial hygiene was occupied with the attainment and preservation of those conditions. After referring to the dangers of dust in its various forms,

and to the different trades in which the workers suffered from swallowing or inhaling it, the lecturer dealt with the metallic bodies which were directly poisonous, and instanced lead poisoning as the most important in that it assumed many forms, and was frequently insidious in its onset. Amongst other diseases of occupation referred to was that of anthrax, which was highly infectious amongst animals and was generally transmitted to man by inoculation. No other disease was so true to the physical condition of dust. Workers chiefly in the sphere of infection were those engaged in the wool industry, in hair factories, and the manipulation of hides and skins. Anthrax was comparatively rare in Britain, though it was estimated that there were about a thousand cases annually, and three were reported in Glasgow last year.

In conclusion he said there must be more medical supervision of workers, and that many cases of trade diseases were still unrecorded and many more were never recognised. Nor could it be otherwise until medical supervision at the factory was followed by medical supervision at the homes of the workers.

Dr. Scott looked forward with interest to the Records of the National Health Insurance Act, as one effect of that Act would be to make accessible a record more thorough and complete of the incidence of disease than anything hitherto obtainable. Only certain diseases were at present notifiable, but under the operations of the Insurance Act it would be possible to obtain from the Insurance records more specific information as to the incidence of diseases of occupation. At present a death might be registered as due to paralysis, but it would be a valuable addition to their knowledge to learn whether the immediate cause of death was traceable to, say, lead poisoning. He seemed to see that they should yet in time be able to discover precisely to what extent the nation was being annually depleted of its workers by disease of occupation which might be preventable.

APPOINTMENT OF GLASGOW PROFESSOR TO SYDNEY UNIVERSITY.

Dr. A. Anstruther Lawson, Lecturer on Botany at Glasgow University, has been appointed to the new chair of Botany in the University of Sydney, New South Wales. He is the first occupant of the chair, and takes up his new duties on March 1st, 1913.

Dr. Lawson, who in the year 1895 began his study of botany under Professor F. O. Bower, has had a most distinguished career, and has become a recognised authority on three phases of botanical study—namely, the gymnosperms, the marine flora, and cytology, and many memoirs on these subjects have been published by him.

Dr. Lawson hails from Fifeshire, his mother being the well-known Scottish novelist, Mrs. J. Kerr-Lawson, and a brother being the artist, Mr. James Kerr-Lawson.

BELFAST.

PUBLIC HEALTH.

DURING the past month there has been a considerable outbreak of scarlatina in Belfast, especially on the Co. Down side of the river. In five weeks 178 cases were reported, and there were a good many deaths. The epidemic is giving some trouble to the authorities, as the parents of affected children try to conceal the nature of the illness to save the children from being taken to the Purdysburn Fever Hospital. In spite of this epidemic, the general health is not bad, and the death-rate last month was 1.7 from zymotic diseases, 4.1 from chest affections, and 14.8 from all causes, as against 15.8 in Cork, 19.6 in Dublin, and 27.1 in Limerick. One very satisfactory feature is that not a single case of typhoid was reported in the city during the month.

THE CORPORATION AND THE FORESHORE.

Mention has frequently been made in these columns of the difficult, and in some respects unique, problem which faces the civic authorities in Belfast—the nuisance caused by the enormous growth of a green

seaweed on the shores of the Lough, between high and low water marks. This weed is the *Ulva latissima*, and already many thousands of pounds have been spent in trying to get rid of it, for it has the peculiar property of giving off sulphuretted hydrogen as it decays, thus polluting the air for miles around. The numberless experts who have been consulted all agree that it grows because of the deposit of sewage on the shore, and committees and commissions have considered the question, while the unhappy ratepayer pays out his thousands. The Belfast Health Commission, the Royal Commission on Sewage Disposal, and a Select Committee of the House of Commons have all strongly recommended one course—namely, the reclamation of a large area on the south shore of the Lough, just below the city, where the weed flourishes. At last the Corporation has decided to take this great work in hand, and at a meeting last week decided to apply to Parliament for the necessary borrowing powers. The work will entail the construction of an earthen mole, faced with stone, about two miles long, and the estimated cost is about £100,000, but this will, in the opinion of many knowing persons, be far exceeded before the work is complete. As against this expenditure, there will be added to the city an area of over six hundred acres of land which will eventually be of great value for business purposes if the city continues to grow as it is doing. There will also be a saving of a large sum—probably as great as the cost of the proposed reclamation, on new sewage works which have to be constructed to try to mitigate the nuisance by treatment of the crude sewage, if the weed cannot be abolished in any other way. And lastly, there will be a saving of £3,000 a year which is now being spent on gathering and carting away the weed from these slob-lands before it has time to decay, and which has but small effect in abating the nuisance.

QUEEN'S UNIVERSITY OF BELFAST.

At a meeting of the Senate of Queen's University, held last week, a new scheme of scholarships was passed, which greatly increases the inducements for able students, both men and women, to enter the University. There will be forty junior scholarships of £40 each, and nine post-graduate scholarships of £50 each, which may be continued a second year. Five of these will be assigned to arts and four to science. There will be no fixed post-graduate scholarships in medicine, but special grants will be made to suitable applicants who desire to prosecute research or clinical studies. There will also be County Council scholarships, but details of these are not yet ready for publication. The new buildings are progressing rapidly. The enlarged Students' Union buildings were opened last week, the new drill hall for the Officers' Training Corps will be opened in a few days, and the new Medical and Science blocks will be ready for next session.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

TREATMENT OF SKIN CASES BY THE HIGH FREQUENCY VACUUM ELECTRODES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—There have been a few dermatological cases reported recently in the medical journals, in which the High Frequency Vacuum Electrodes have been used; in my opinion this method of treatment is not practised so extensively as it deserves to be, seeing that it is easy of application, comforting to the patient, and in experienced hands, generally with signal success. This is my excuse for reporting briefly a few cases picked at random from my note book, which I treated early in the year.

1. *Psoriasis*.—Master D., æt. 16, affected for three or four years all over the body, especially back, sides, legs, forearms and scalp—disappeared after 16 treat-

ments with a medium vacuum tube; Liq. arsenicalis and Tr. Rhei Co. internally, no local application.

2. *Alopecia Areata*.—Mrs. K., æt. 35;—duration four months, four patches each about the size of a five-shilling piece. Hair commenced to grow after third application of high vacuum tube. Seven treatments in all.

3. *Dry Seborrhœa of Scalp*.—Mr. G., æt. 32—duration uncertain. Scalp almost clear after 12 applications of high vacuum electrode, made especially for me by Messrs. Newton and Wright of London, in appearance like a three-pronged fork with small points, thus passing easily through the hair.

4. *Gouty Eczema*.—Mr. C., æt. 65—duration 10 years, legs, arms, head and back, in irregular patches. Appearance normal, except some redness after 10 sittings with low vacuum tube. Dieting, citarin internally, nothing locally.

5. *Psoriasis*.—Miss C., æt. 39—duration two years, on outer sides of arms and legs near elbows and knees. Cleared up entirely after the 12th treatment with a medium vacuum tube. No medicine.

6. *Facial Eczema* (slightly moist)—Mrs. B., æt. 45,—duration three or four weeks. Cucumber juice and glycerine allowed to be used. Well after the third application of a low vacuum tube.

7. *Pruritus perinei*.—Mr. W., æt. 50—suffered as long as could remember, the itching being intolerable at night. No local application had any effect. Relieved after the third application of a medium vacuum tube and condition normal after the eighth treatment.

8. *Chilblains*.—Miss V., æt. 12—always suffered during winter, on hands and feet, on this occasion lasted two weeks. The third application of a medium vacuum tube, permanently relieved.

9. *Chronic Onychia*.—Mr. C., æt. 32—duration three months, all fingers. Ung: zinci oleas used locally. Healthy condition restored after four treatments with a fairly high vacuum tube.

10. *Acne Vulgaris*.—Miss K., æt. 18—forehead, cheeks and chin affected for two or three years. Cured after 10 applications of a medium vacuum tube.

Yours truly,

W. A. GRIGGS.

60, Montpelier Road,
Brighton.

October 30th, 1912.

COTARNINE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—During the past five years I have had occasion to prescribe the phthalate of cotarnine for uterine hæmorrhage of many kinds, and in no case did I get good results from the drug until I gave ten grain doses. In one case ten grain doses were given every two hours until twelve were taken, without the least unpleasant result. My rule is to give the drug at intervals of two, three, or four hours, according to the severity of the case. In a few instances the patients complained of nausea, and in all the bitter unpleasant taste of the medicine is adverse to its continued use. As a styptic I found it superior to any therapeutic agent I ever prescribed, and my object in writing is to show that it may be prescribed in much larger doses than those recommended in our ordinary text books. Martindale (*Extra P. ed.* 14) gives the dose as $\frac{3}{4}$ of a grain; Fortescue-Birkdale gives $\frac{3}{4}$ to 1½ grain, three to five times daily; König, however, gave 5 grain doses (*Wien. Klin. W'och.*, 1909). Bocquillon's (*Med. News*, 1912) largest dose is 7½ grains daily in deviated doses; and Hare (*Practitioner*, 1912) gives the dose as from $\frac{1}{2}$ grain to 4 grains three times a day.

I am, Sir, yours truly,

GEORGE FOY.

DUBLIN

IRELAND AND THE INSURANCE ACT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In view of the latest pronouncement by Mr. Lloyd George, outlining his present financial attitude

towards those members of the medical profession who accept service under the Insurance Act, may I request the hospitality of your columns to make a few suggestions, inasmuch as the situation created by the Chancellor's partial concessions affects the profession in Ireland.

It seems to me that the best, in fact, the only way of ascertaining the trend of Irish medical opinion is by convening a general meeting of our confreres throughout the country, to be held in Dublin at an early date, to which every district, urban and rural, would send a delegate.

At this meeting it might not be inopportune to analyse closely the reasons why the Irish contributor should be denied medical benefit, as the granting of such benefit seems to most thinking people the sole *raison d'être* of this Act. Thanking you in anticipation.

I am, Sir, yours truly,
THOMAS C. McGRATH.

130, North Strand Road,
Dublin. Oct 29th,

THE MIDWIFE—AN ANACHRONISM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Attention to a parturient woman is one of the most ancient branches of the practice of medicine, and probably owing to its antiquity, still shows a marked example of the survival of the unfit. Obstetrics nowadays, in the hands of competent practitioners, is on a scientific plane, parallel with any other of the healing arts. Unfortunately only a small part of the practice is in the hands of these men. The rest is carried out more or less successfully by midwives, who cannot pretend to the preliminary education and high technical skill that is universally admitted to be absolutely requisite for the efficiency of any branch of the practice of medicine. This duplication of practice is radically wrong; from a misplaced excuse of expediency we have deliberately adopted a standard we know to be ineffective. To argue that a midwife is competent to deal with a large proportion of cases is analogous to encouraging a pharmacist to prescribe for minor ills, and to call in a physician only when the case is obviously beyond him. In an event which civilization has reduced from a physiological function to something not far from a pathological condition, it is illogical to have an untrained—or worse, a half-trained—individual to bear the responsibility of two lives, and only to hand the case over to one able to deal with it when often it is too late. Let us improve our midwives, by all means to the utmost of their capacity—but let us ultimately abolish them. They are an anachronism; if we must have them, let them be competent anachronisms, but the proper treatment of the midwife is not to educate, but to eliminate her.

I am, Sir, Yours truly,
PRACTITIONER.

MR. LLOYD GEORGE'S LAST OFFER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am in thorough agreement with the views put forward in your leading article of October 30th on the subject of Mr. Lloyd George's recent proposals. They will require the very careful consideration of the profession, and it is of the utmost importance that whatever decision may be arrived at should be loyally carried out by every member of the profession. In forming a decision it is necessary that the proposals of Mr. Lloyd George should be put accurately and clearly before medical men. The Chancellor, himself, whether intentionally or not, has failed to make his proposals quite clear, and I regret to note that in one particular you appear to have been misled by him. Having quoted Mr. Lloyd George, and stated quite accurately the demands of the profession, you remark: "The outcome of the proposals, if we interpret Mr. Lloyd George's proposals correctly, is that medical men are offered a capitation fee of 7s., which in some instances, will be increased to 7s. 6d., that amount to

be exclusive of drugs. The first point to be settled is whether 7s. is to be accepted in view of the demand for 8s. 6d."

How is this 7s. arrived at? Mr. George proposes a capitation fee of 6s. 6d. for the medical benefit. The extra 6d. is only got by dragging in the sanatorium benefit, about which there has been, so far, no dispute. The profession has asked for 8s. 6d. plus extras for the medical benefit, not for the medical benefit plus the sanatorium benefit. They are offered 6s. 6d., and 6s. 6d. only, for the medical benefit, and this inclusive of extras.

I am not concerned at present to argue whether this offer should be accepted or not. My object in writing is merely to make its terms clear. Further, whether it be accepted or not, the sanatorium benefit is not affected.

I am, Sir, yours truly,
HARD TIMES.

November 1st, 1912.

THE ANTISEPTIC TREATMENT OF PHTHISIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the report in the *Daily Telegraph*, October 30th, of the case of Stevens v. the British Medical Association, Dr. Acland stated in his evidence that "Every kind of antiseptic had been tried and was ineffective." No antiseptic treatment, as far as I am aware, has been tried in a proper and scientific manner, for when the Reports of the old Pharmacopoeia were excluded from recent editions, it is quite clear that the only plan of treating pulmonary diseases on antiseptic principles was abandoned. Medicines taken in the ordinary way, that is into the stomach, can have little or no effect on tubercular phthisis in its active stage. It would be as reasonable for the surgeon to use antiseptic medicines in the hope of preventing the septic troubles that occur in surgical practice. It is by atmospheric influence and that alone, that we can hope for prevention and arrest of pulmonary tuberculosis. Dr. Acland seems to think that everyone is tuberculous, or that "a large proportion of the population was tuberculous at some time or other." The great principle of antiseptic treatment of lung disease has never yet been properly tested, and till it is we shall see no great change in the morbid effects of tuberculosis in this country.

I am, Sir, yours truly,
ROBERT LEE.

West Drayton, November 2nd, 1912.

OBITUARY.

DR. L. W. D. MAIR, OF LONDON.

By the death, on Sunday last, of Dr. Ludovic William Darra Mair, at the early age of 46, the Local Government Board has lost one of its most distinguished medical inspectors. The deceased, who was the son of Dr. R. Slater Mair, formerly of Madras, was educated privately in London and at Epsom College. He entered St. Bartholomew's Hospital with a scholarship in 1883, and graduated M.D. with Honours at the University of London in 1893. After two years' work at the Coppice Asylum, Nottingham, he entered the Public Health service as Medical Officer of Health of the rural district of Croydon. Here his ability came under special notice at the Local Government Board, and in 1898 Mr. H. Chaplin appointed him a Medical Inspector in that Office. Dr. Mair carried out for his department many important investigations into the aetiology of infectious diseases in different parts of the country, the reports of which have formed valuable contributions to epidemiology, while other reports have had important bearing on the sanitary administration of rural districts. The results of an inquiry on the incidence of disease on the inhabitants of back-to-back houses in Wickham in 1907 led to his being commissioned to make a wider investigation on the subject, which is contained in a special report presented to Parliament in 1910. Dr. Mair served as a member of the Commission appointed

by the Irish Local Government Board in 1908 to inquire into the causes of the high mortality of Belfast, and was specially concerned with the discovery of the large scale on which sewage-polluted shellfish had produced enteric fever in that city. He took an important part in the investigation of the outbreak of arsenical poisoning in Lancashire in 1900, and was Chairman of the Departmental Committee on the use of intercepting traps in house drains, which reported this year. Dr. Mair married, in 1894, Edith, daughter of Dr. W. B. Tate, of Nottingham, and is survived by his widow and two daughters.

DR. F. BAGSHAWE, OF ST. LEONARDS-ON-SEA.

We regret to announce the death of Dr. Frederic Bagshawe, J.P., which took place on the 2nd inst., at his residence at 35 Warrior Square, St. Leonards-on-Sea, where he had lived for over 40 years. He was for six years an alderman of the borough, and in 1897-8, the year of the extension of the borough boundaries, he was Mayor. Although nearly eighty years of age, he was actively engaged in his work almost to the last. Dr. Bagshawe came of an old Derbyshire family, his father having been rector of Eyam. He graduated M.B. at Cambridge in 1861, becoming M.D. in 1865, having studied at St. George's Hospital and Cambridge. He became a Fellow of the Royal College of Physicians, London, in 1879. Dr. Bagshawe began to practise at Hastings in 1865, and for many seasons had an important practice on the Riviera. In 1871 he was appointed Assistant Physician to the Hastings and East Sussex Hospital, and was largely concerned in the rebuilding of the Hospital on the circular ward plan. He afterwards became Physician to the hospital. He had held medical appointments at the London Western General Dispensary and at the Hospital for Sick Children, Great Ormond Street. He was a former President of the South-East Branch of the British Medical Association and of the British Balneological and Climatological Society.

REVIEWS OF BOOKS.

TREATMENT OF CURVATURE OF THE SPINE AND FLAT FOOT. (a)

THIS work, of about 130 pages, is intended as a guide to the management and physical training of patients suffering from scoliosis and flat foot. It is not an exhaustive review of the whole subject from a specialist's point of view, but rather confines itself to imparting the kind of information that the general practitioner requires, and should appreciate, when he meets cases which are not too advanced for him to undertake without special study.

Mr. Smith's book is divided into ten chapters, the first of which is historical and introductory. In the following chapters the occurrence and causes of lateral curvature are clearly treated. Chapter IV., on "Analysis of the Deformity," gives an interesting account of some of the author's experiments, to show the important part played by the ribs in causing rotation. The author takes next the Examination of the Spine, and the classification of cases are considered in a practical way. He further explains the "rationale and technique of Prof. Rudolf Klapp's 'Creeping Exercises,'" which have been found so useful in mobilising the spine and strengthening the muscles attached thereto. Standing, sitting and bench exercises are discussed, and the subsequent chapters are devoted to the consideration of weak ankles, and their treatment by boots, manipulations, and exercises. The final chapter is a judicious addition to the work, on the general treatment of the patients by iron and cod-liver oil.

The book contains 82 figures, which are all good; those illustrating the human form in faulty positions,

(a) "Lateral Curvature of the Spine and Flat Foot, and Their Treatment by Exercises." By J. S. Kelllett Smith, F.R.C.S. Eng. Pp. 130, 82 Illustrations. Bristol: John Wright and Sons, Ltd. 1911.

and while doing corrective exercises, being particularly instructive. We can recommend the work as a convenient and easily assimilated little treatise on the subject.

DR. MURPHY'S CLINICS. (a)

WE all know that Dr. Murphy, of Chicago, is an able and original operator, and we accordingly look forward with pleasure to reading any work that bears his name. It is not often that we are disappointed. Dr. Murphy is responsible for much of the best American teaching on his own subjects. Still he is not infallible, and this series of Surgical Clinics is one of his mistakes.

A bedside clinic is perhaps the most effective, as it is certainly the most interesting, way of giving students a vivid and living impression of the facts that lie before them, and it is probable that the lectures delivered by Dr. Murphy give benefit well above the average to those who are fortunate enough to hear the spoken word at Mercy Hospital.

But printed verbatim reports of these lectures, with only such illustrations as were handed round the class, are another thing.

It may occur to one that the patient occupies a not altogether unimportant position in a bedside clinic, and some might think him essential. Not so Dr. Murphy.

After giving us the patient's name, occupation, and skiagrams, the rest is left to our imagination. We have every word that falls from the Master's mouth, how he instructs his interne in history-writing, how he answers futile questions, even how he exhibits a praiseworthy niceness in the use of English prepositions, but the condition around which it all centres is utterly and completely disregarded. We have all the minutiae of detailed comment on a subject that we have no means of visualising and great difficulty in comprehending.

The result is that some of these reports are quite unintelligible. If we had been in the Theatre of Mercy Hospital and had seen and listened to Dr. Murphy as he talked his way through the steps of the operations, we would probably have had an extremely clear picture of what he was doing, but to a reader the discourse is meaningless.

"I am going to make this incision in my flap," "I sew that across here," without any further word of explanation, mean no more than so much blank paper to a man six months and four thousand miles away from the speaker. The pity of it is that there is excellent material in these volumes, but nearly all of it is wasted. It is inconceivable that the author can have bestowed much trouble on these reports from the time they were taken down in shorthand to their issue to the public. Admiration for the stenographer's conscientiousness and exasperation at the carelessness that offers so much and gives so little are the feelings with which we close these books.

BIOLOGICAL PRODUCTS IN MEDICINE. (b)

IF some still continue to find solid grounds for their ignorant enthusiasm for modernistic revelation in the fact that many so-called "scientists" who pose as apostles of its doctrines find their "master key" in the blessed process of *Evolution*, there are still other some who have come to the conclusion that *Revolution*—vigorous progression in a circular rut, with periodic recurrences to the original starting point—is a term more appropriate to designation of the nature and quality of the degree and direction of the advancement of the science of therapeutics. The appearance of the present volume, and the inspiration which led to its production, furnish a conspicuously clear and, indeed, we believe, convincing item of testimony to the validity of our thesis. For the *opotherapy* of the opening years of the twentieth century appears to be

(a) "The Surgical Clinics of John B. Murphy, M.D., at Mercy Hospital, Chicago." April, June and August, 1912. Philadelphia: W. B. Saunders Company. 1912. Price 35s. per annum.

(b) "Les Produits Biologiques Médicinaux." By P. Byla et B. Delaunay. Paris: Societe d'Éditions Scientifiques et Médicales, F. Gittler. 1912.

regarded by the average practitioner of the present day, as it unquestionably is by the average intelligent non-medical citizen, as a relatively novel result of the most modern therapeutic research. And yet the plain, unvarnished fact is that this method of patching up the rents attributable to infirmities of the flesh, and supporting the functional weaknesses of failing organs, is one of the very oldest known to the annals of the art of healing. And, when we come to consider the subject with some special care, nothing can be regarded as more natural—having due respect to the inherent defects of the undisciplined human understanding—than that such should be the case. The Anglo-Saxon physician of the present generation has proved himself slow in adopting the methods of "organo-therapy," because his therapeutic armamentarium was originally furnished on absolutely uncongenial principles. Even at an early stage in the multiplication of the human race, the more stolid and long-suffering were allowed to function as tillers of the soil; while the more intellectually accomplished had secured the position of a recognised hierarchy, one of the special perquisites of which was the receipt of the more savoury and sustaining tit-bits derivable from the animal kingdom. Wizard—or witch-finder, medicine-man—or rain-maker, prophet—or priest: the representative champion of the natural supremacy of mind over matter—adapted his weapons for mental conquest to the collective intelligence and "evolutionary" status of the community in which he had been providentially called to exercise his functions and display his special skill. Thus the priestly adviser of the primitive tribe secured for himself the most desirable of its animals for propitiatory sacrifice—and used the most savoury and nutritious of their organs—and special anatomical areas—for his personal consumption. He was the only expert who had cultivated special skill, beneath the common area of "surface anatomy;" and he had studied the nutritional properties of the various portions of the animal body in a way that no other member of the tribe could pretend to have done. And the "natural" verisimilitude of the view of the adaptability of the substance of any of the various organs of the animal body to the reinforcement of the corresponding ones of the human organism which had come to display evidence of functional failure, would surely appeal to the judgment of "the general" with incontrovertible force. What could be more natural than that assimilation of the digested cardiac tissues of the "King of Beasts" should restore to the failing cardiac organ of man or woman a *quantum* of the exuberant strength which had conferred upon its former owner his proverbial power and dignity. The view cannot safely be scoffed at by the advocates of the *thyroid* and *suprarenal* preparations of the present day, surely. This highly rationalised code of special therapeutics retained its force of appeal throughout prehistoric antiquity, and down through the classic ages. It was even reinforced in the mediæval centuries, when it became endowed with occult attractiveness. It was not by any means wholly rejected with the dawn of modern scientific enlightenment and research; as the colossal encyclopædia of Matthioli, the "father of modern therapeutics," well shows. It faded with the tidal wave movement of chemistry and physiology in the mid-decades of the nineteenth century, and the first great step towards its resurrection was displayed in the employment of cod-liver oil as the cure for pulmonary consumption. The most obvious change in the consumptive's physique was loss of fat; the obvious indication of the treatment was to replace it; and an early discovery of physiological chemistry was that cod-liver oil saponified more readily in alkaline solutions than other fats.

The authors of the interesting volume before us deserve the full credit of treating the subject of *opotherapy* from the point of view of the most modern science; and the information given regarding the composition, properties, and (real or fancied) therapeutic powers of ferments, albuminoids, lipoids, etc., make highly instructive and suggestive reading.

SPRUE. (a)

THE appearance of this neat volume is quite opportune, as a commission started for Ceylon but a few months ago, for the purpose of unravelling, as far as possible, the tangled problems presented by the disease of which the author here undertakes to give his readers the benefit of a prolonged and exceptional experience. The author regards the troublesome and inveterate (so-called) tropical diarrhoea as sprue itself. And having regard to the usually hopeless nature of this condition, when allowed to remain unchecked at the onset, he is specially emphatic in his warnings, and his reiteration of the vital importance of promptitude: "Let the first indication of troubled bowels, from whatever cause, be instantly treated on the lines of purification, just as would be done with suspected drains in a house. Apply germicides long before the invader has had time to entrench himself and obtain the shelter from which it becomes increasingly difficult to dislodge him. If this were the rule, I go so far as to believe that English consultants would never find a case of chronic sprue in their waiting-rooms." And immediately following this statement—which, we must remark, is made with the confidence of a skilled and earnest observer, anxiously embracing the opportunity of conveying truth with emphasis, rather than with the sonorous enunciation of the pretentious quack—ne unfolds the secret of his success. "After I had found out the value of santonin I never had to invalid a patient home during the thirteen years I still continued to practise in China. Interesting (and hopeful) it is to notice that this addition to our small stock of *specific* remedies, thus comes from the far Eastern territory, which anticipated us by several thousands of years with its gunpowder, and block-printing, and marine compass, and surface anatomy."

The approximate uniformity of the malignant attack on the mucous lining of the whole alimentary canal is well portrayed by our author, both by descriptive text and reproductive illustration. The bacteriology of the disease does not, however, appear to be finally settled, at least as regards nomenclature, although thirteen distinct varieties of organisms have been isolated from a "single drop of fluid motion," and "one variety of bacillus behaved in a destructive manner." But "the most marked sign of active sprue is the contractive condition of the liver, yet nothing has been found *post mortem* to account for this." The most important of all points of view in serious disease is, however, that of the therapist; and if we have a specific agent in santonin the great question is answered once and for all. But its use requires special precautions. The discovery of the value of santonin was made by the author when "using a bottle of the drug which had been exposed to the tropical sunshine of China for over fourteen years." And he warns the reader (in italic type) that "the white drug is absolutely useless in sprue, and its value increases directly as the colour changes."

TREATISE ON TREATMENT. (b)

THERE are certainly better and worse treatises on treatment in the market than this Indian production, which consists for the most part of a collection of recipes and advice culled from various medical journals. There are several misprints and mistakes. Thus "Lint Iodine" (p. 23) is not very good Latin, and, besides, the present B.P. preparation is the liq. Iodi fortis, not the linimentum. "Extr. nucis vomica liq." (p. 22) is also bad form. Then, again, what are "Chloral Amid," (p. 28), "Oil Recini" (p. 305), "Lethium formate" (p. 569), and so on? Dr. Bramwell, of Edinburgh, is raised to the Professorship on p. 555! Nor do we like the method the author adopts of advertising his book in a circular which

(a) "Sprue: Its Diagnosis and Treatment." By Charles Begg, M.B., C.M. Edin., Formerly Medical Officer, Chinese Imperial Maritime Customs, and H.B.M. Medical Officer, Hankow, China. Pp. 124. Illustrated. Bristol: John Wright and Sons, Ltd. 1912. Price 6s. net.

(b) "A Treatise on Treatment." By Jogender Lal Chundra, L.M.S., Calcutta University. Calcutta: S. Gopee Kristo, Paul's Lane. 1911.

accompanies our review copy. Altogether our task was rather a difficult one on this occasion on account of the strong odour of naphtha which emanated from the volume, the reason for which was not quite apparent. We hope Sir William Broadbent would not object to the spelling of his name on p. 377. We strongly advise the author to secure the services of a good proof reader when next he appears in print.

MEDICAL NEWS IN BRIEF.

The Lord Mayor's Dinner Party.

THE Lord Mayor gave a dinner party at the Mansion House last week to meet Sir Thomas Barlow, the President of the Royal College of Physicians, and Sir Rickman Godlee, the President of the Royal College of Surgeons.

Among the guests were Sir Douglas Powell, Sir William Church, Sir William Osler, Sir Clifford Allbutt, Sir Lauder Brunton, Sir Frederick Treves, Sir Dyce Duckworth, Sir Henry Morris, Sir Francis Champneys, Sir James Porter, Sir Watson Cheyne, Sir James Goodhart, Sir Anthony Bowlby, Sir J. Rose Bradford, Sir Malcolm Morris, Sir George Savage, Sir Edward Busk, Sir Robert Moran, Sir William Bennett, Sir John Tweedy, Sir A. Pearce Gould, Sir Cooper Perry, Sir John Broadbent, Sir Frederick Hewitt, Sir Shirley Murphy, Sir Henry Miers, Sir William Collins, Sir Anderson Critchett, Dr. Léon Blanc, Mayor of Aix-les-Bains, Dr. Herringham, Vice-Chancellor of the University of London, and Dr. Bramley Taylor, Master of the Society of Apothecaries.

Friendly Societies in Dublin.

SPEAKING at a meeting in Dublin of the Friendly Societies' Union, Mr. J. D. Nugent, P.L.G., referring to the institution of the Union as a result of the extraordinary demand by medical officers of the friendly societies, said that the Union should become a permanent institution, which, when the medical question had been settled, would be beneficial alike to members and officers of the various societies.

The Chancellor of the Exchequer's recent statement did not, in Mr. Nugent's view, alter the situation very much, because, not having medical benefits in Ireland, the whole of the doctor's fees would have to be paid by the individual member through the benefit society. As to the proposal that the Friendly Societies' Union act in the capacity of medical committee, and receive a capitation grant of 5s. and employ doctors to do the work, it would be no infringement of their compact for doctors to accept salary. Apart from two offers from Dublin doctors, an Association in Scotland was willing to send Irish doctors across to take up salaried duty. He was informed by the Insurance Commission that approved societies could dispense with medical certificates and accept the recommendation of their health visitors. The establishment of a Municipal Hospital would solve the hospital crux. He would oppose the application of medical benefits to Ireland unless it covers the wife and dependent children under 16 years of the insured person.

A resolution was adopted for the payment of the 5s. capitation grant into the Union, with authority to employ doctors on salary; and it was agreed that medical benefits should not be extended to Ireland except on the principle mentioned by Mr. Nugent.

State Medical Service Association.

THE first general meeting of this Association, inaugurated at Liverpool in July last, was held in London on October 25th. The secretary reported that as a result of sending out 625 circulars 135 medical men had become members, and a few laymen. The chairman, Professor Benjamin Moore, laid stress on the fact that the great aim of the Association was gradually to educate the medical profession and the public to the need of a State Medical Service which should put professional advice at the ready disposal

of every member of the community who needed it, with a view to the prevention of disease.

An executive committee was appointed, with Dr. G. A. Heron as chairman, and arrangements were made for the formation of district branches. Negotiations for the issue of a weekly journal, as the official organ of the Association, to be entitled *The Medical World*, were satisfactorily completed. All communications should be addressed to the Hon. Sec., Charles A. Parker, Esq., F.R.C.S., 24, Upper Wimpole Street, W.

Mental Deficiency Bill.

The following resolutions have been passed by the Conjoint Committee of the B.M.A. and I.M.A. :—

That every effort should be made to have Ireland included in the scope of the Mental Deficiency Bill now before Parliament."

"The report of the Royal Commission on the Feeble Minded shows clearly that it is more urgently required in Ireland than in Great Britain. Should Ireland be excluded from it a large sum of money will be lost to this country."

New University College Buildings, Dublin.

LAST week the Governing Body of University College, Dublin, made known the fact that they had confirmed the assessor's award, and accepted the designs of Mr. R. M. Butler for the proposed new buildings of the University, which are to be erected on the site of the old Royal University at Earlsfort Terrace, Dublin. In accordance with Mr. Butler's plans, a new façade, with a projecting portico, will be erected forty feet in front of the present structure, and will extend similarly along the Hatch street frontage and the northern frontage. The rear of this new building will abut on what remains of the present structure when the existing front has been removed, so as to allow the present great hall, convocation hall, and other adjoining rooms to form an integral part for the present of the new structure. It will thus be seen that the existing buildings will be enveloped by the new structure, and a pleasing prospect presented. Eventually the old buildings will be removed and the new building completed according to the design by a back line of buildings running parallel to the new front, and connecting the two wings, thus forming a square. A central line of buildings will divide the enclosed space into two quadrangles. This axial line of buildings will contain an assembly hall, library, and a large college theatre with annexes. The façade facing Earlsfort Terrace will be 512 feet long, and that facing Hatch Street 272 feet. The building will be about 68 feet high. It will be surrounded by an open space of about 40 feet wide. It is proposed to proceed, in the first instance, with a portion only of the entire scheme. The cost of this portion is not to exceed £95,000. The cost of the entire scheme is not to exceed £160,000. The design was frankly based upon the work of the eighteenth century, as exemplified in the public buildings of Dublin.

A Death from Veronal.

THE death of Mr. Thomas Shaw (45), the London dramatic agent, formed the subject of an inquest at Kingston last week. It was stated that he had been in the habit of taking veronal tablets to induce sleep, and that after taking some on Friday night he died the following morning.

Mrs. Shaw told the Coroner that her husband usually took two tablets at a time, but between Thursday night and Friday night he took no fewer than ten. This said the Coroner, represented 50 grains. He went on to point out that what might be a safe dose at one time might not prove so after an interval. It was stated that veronal could be bought as easily as soap. Death was due to heart failure, accelerated by veronal poisoning. A verdict of "Death from misadventure" was returned.

Dr. Burke-Savage Memorial Fund.

THE following appeal has been issued :—

The death of Dr. Matthew Burke-Savage has created a deep feeling of sorrow amongst a great number of

friends to whom he had endeared himself by his many sterling qualities. His brilliant professional gifts had won for him a foremost place in public estimation, whilst his kindness of heart and his warm interest in the welfare of others had gained him a place in the hearts of many, who deeply deplore his loss. He had devoted himself with such single-mindedness and self-sacrifice to the well-being of others—totally forgetful of his own material interests—that he failed to make adequate provision for the young and helpless family whom he loved so well. A committee has been formed to appeal on their behalf to the generosity of the many who knew and appreciated Dr. Savage for his many great qualities, and, not least, for his life-long devotion to the poor.

(Signed) MICHAEL F. COX, *President.*

J. S. M'ARDLE,

J. S. WILSON,

Hon. Treasurers.

DENIS KENNEDY, *Hon. Secretary.*

Subscriptions will be received by the Hon. Treasurers, Gresham Hotel, or at the Belfast Bank, 86, Talbot Street, Dublin.

Royal College of Physicians of London.

LECTURES.—Dr. Raymond Crawford will deliver the FitzPatrick Lectures on "The History of Medicine" on November 7, 12, 14 and 19, the subject being "Echoes of Pestilence in Literature and Art." The first lecture will be entitled "To the Great Antonine Plague," the second "To the Black Death," the third "To the Great Plague of Milan," and the last "To the End of the Eighteenth Century."

The Horace Dobell Lecture by Dr. C. J. Martin on "Insect Porters of Bacterial Infection" will be delivered on Thursday, November 21.

Institutions Recognised.—On the recommendation of the Committee of Management of the Examining Board in England, the following schools were added to the list of institutions recognised by the Board for instruction in biology:—West Bromwich Municipal Secondary School and King Edward's School, Birmingham. In chemistry and physics:—Leamington Spa Municipal Technical School and King William's School, Castletown, Isle of Man. The Naval Medical College at Greenwich was added to the list of laboratories recognised for the course of instruction for the diploma in public health, and the East Ham Borough Isolation Hospital to the list of fever hospitals. Dr. Norman Moore was elected a member of the Committee of Management of the Examining Board in England.

At the quarterly meeting of the Council on Thursday last, the following new members and licentiates were admitted:—To be members of the College (M.R.C.P.):—J. Davis Barris, M.B.Camb., F.R.C.S., L.R.C.P., St. Barth., and A. N. Contractor, M.D.Lond., L.R.C.P., and M.R.C.S., of Univ. Coll. Lond.

To be Licentiates (L.R.C.P.):—A. Ashmore, E. Bach, N. K. Bal (Bombay), H. R. Bastard, G. E. Beaumont, P. L. T. Bennett, L. G. Bourdillon, R. St. L. Brockman, R. G. Brown, E. N. Butler, L. T. Challenor, P. C. Cole, L. G. Grossman, K. F. R. Davison, A. E. L. Devonald, G. R. Dobrashian, S. Daraisamy (Madras), F. N. Doubleday, F. P. Duncan, W. J. I. Dwyer, T. L. Ellis, M. S. Esler, B. C. Ewens, E. G. Fisher, W. B. Foley, W. K. Fry, V. Gabriel (Ceylon), G. E. Genge-Andrews, D. M. Gibson, R. S. Graham, J. Greene, M. J. Haffey, D. B. I. Hallett, W. J. Hart, H. Harvey, H. J. B. Heelas, C. Helm, H. J. Hoby (New Zealand), R. L. Horton, D. E. J. S. Hughes, A. Jackson, E. B. Jardine, D. D. B. Jay, H. W. Jones, R. A. Jones, S. Keith, C. Kennedy, W. J. T. Kimber, G. A. M. Leopold (Tubingen), T. P. Lewis, J. B. Lowe, W. C. D. Maile, C. C. Marshall (Melbourne), L. A. Martin, G. O. Maw, J. N. Mehta (London), N. M. Mehta (Bombay), R. H. Miller, G. W. Mitchell, S. G. Papadopoulos, S. G. Platts, E. G. Reeve, W. R. Reynell, J. F. G. Richards, I. Ridge-Jones, G. H. Roberts, W. Robinson, H. C. Rook, G. A. Russell, C. M. Ryley, J. G. Saner, R. Saravanamuttu (Madras), F. R. Scott (Toronto), A. S. Seabrooke, H. N. Sealy, W. J. D. Smyth, J. B.

Stringer, A. L. Sutcliffe, W. F. Thompson, H. E. Thorn, W. C. Toll (Toronto), D. B. Truman, C. R. B. von Braun, J. R. Waddy, G. A. Walker, H. Walker, J. F. Ward, M. H. Watney, W. G. Watson, W. L. Webb, H. N. Webber, G. J. Whetham (Toronto), A. Wilson, E. Wordley and A. M. Zamora.

A diploma in tropical medicine was granted jointly with the Royal College of Surgeons to Eric S. Marshall, L.R.C.P., M.R.C.S., of St. Bartholomew's and the School of Tropical Medical.

Royal Colleges of Physicians and of Surgeons of Edinburgh and Royal Faculty of Physicians and Surgeons of Glasgow.

At the quarterly examinations of the above Board, held in Edinburgh, which were concluded on October 26th, five candidates passed the First Examination, twelve passed the Second Examination, eleven the Third Examination, and the following candidates passed the Final Examination, and were admitted L.R.C.P.E., L.R.C.S.E., L.R.F.P., and S.G.:—Alfred G. Cowper, Bombay; James McFarlane, Jarro-on-Tyne; Dodballapur S. Puttanna, Dodballapur; Narain R. Ubhaya, Mangalore, India; William Martin, Ballynabinch; Eslyn Marcar, India; William Watson, co. Tyrone; Alexander D'Sousa, Bombay; Charles J. L. Patch, Madras; Hamilton Mathewson, co. Tyrone; Walter Lessey, Grenada; Hormusji S. Dastur, Broach, India; Verdon C. H. Dearden, Sheffield; and John I. Arnold, co. Wexford; 4 also passed in Medicine, 3 in Surgery, 6 in Midwifery, and 9 in Medical Jurisprudence and Public Health.

University College, Dublin—College Scholarships.

FACULTY OF MEDICINE.—Second year (£30 each)—Thomas J. X. Canton; John J. Cowley and John A. O'Tierney, ex æq.; Mary J. Farrell. Third year (£30 each)—Francis de C. Keogh, Elizabeth M. J. Kelly, John J. Cremin, James B. Magennis, Charles I. Hannigan. Prizes (£15 each)—Edmund F. Higgins, James P. Moriarty. Fourth Year (£30 each)—John G. J. Green, Michael M. Davitt, Edward T. Freeman, Arthur H. Flaunery, Thomas J. Costello, Mary C. M'Kenna. Prizes (£15 each)—Michael M'Keever, John A. Sellars. Prize (£10)—Edward P. Carey. Fifth Year (£30 each)—John E. Harford, Evelyne Noble. Prizes (£15 each)—Keiran M'Grath, Richard B. Hennessy.

Trinity College, Dublin.

MICHAELMAS TERM, 1912.—The following candidates have passed the Final Medical Examination:—Part I.: Frederick C. Fleming, passed on high marks; Joseph C. A. McCalden, John G. Butt, Blacker C. Powell, Herbert E. Murray, George B. Hadden, William R. L. Waters, Quentin V. B. Wallace, John S. Dockrill, William Foot, William A. Ryan, Robert W. Chapman, and Arthur N. Brady.

Diploma in Public Health.—Part I.: Francis R. Coppinger; Part II.: Francis R. Coppinger.

Intermediate Medical Examination.—Part II.—The following candidates have passed:—Eric Lumley, James C. McWalter, George H. Wood, Bertram Sheridan, Frank Healy, Maurice King, and Joseph P. Quinn.

Preliminary Scientific Medical Examination.—Chemistry and Physics.—The following candidates have passed:—Thomas P. Chapman, Robert Ramsay, Alan Grimby, John McClelland, William McClintock, Charles Comerford, Thomas Roche, John Westby, Cecil Keller, Thomas Lane, Edward Lipman, Rupert Gordon, Mortimer McGee-Russell, Frank Ferguson, Philip Hall, Alfred Price, Benjamin Merrin, Henry O'Kelly, John E. Hill, Cyril Littledale, and James Leahy.

Botany and Zoology.—The following candidates have passed:—Eric Beatty, John Westby, Charles Herbert, Sydney Furlong, Meta Jackson, Francis O'Connor, Margaret Wolfe, William Colhoun, Marie Hadden, Thomas Dorman, and Roney Patterson.

Preliminary Scientific Dental Examination.—Chemistry and Physics.—The following candidate has passed:—Mary de Sales Magennis.

NOTICES TO CORRESPONDENTS, &c.

✎ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS.

FOR ONE INSERTION.—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d. The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces. Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES on LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

IMPORTANT MUNICIPAL VACANCIES.

Two vacancies of more than usual importance will be found in the advertisement columns of our present issue. One is the appointment of Medical Officer of Health for the City of London, at a salary of £1,000 per annum, applications to be delivered before the 11th inst. The other is an appointment as School Medical Officer, under the Education Authority of the City of Liverpool. Applications must be lodged before the 15th inst.

"SEMPER PARATUM" (Colchester).—The fact of the disappearance of cutaneous lesions, when symmetrical, after vigorous mechano-therapeutic treatment has been applied to one side only is not unknown. Quite recently Delbanco, of Hamburg, has reported the rapid involution of common warts upon the back of both hands after the application of X-rays to one hand only. Other observers have noted a similar disappearance of symmetrical psoriatic and eczematous patches after treatment of one side only by the solid carbon dioxide.

THE HEALTH OF LONDON SCHOOL CHILDREN.

THE scheme for the medical treatment of London school children during 1912-13, which is proposed by the Children's Care (Central) Sub-Committee, provides for the treatment of 48,613 defects, or, omitting minor ailments of 39,238 defects. During the year ended December 31, 1911, the total number of eye, ear, nose and throat defects and ringworm cases was approximately 65,000, and during the year ended July 31st, 1912, 60,000.

Dr. P. A. (London, E.).—We understand that a school of mother-craft, having similar aims to the one you mention, has just been started at the Acton creche by Dr. Lilian E. Wilson, Assistant Medical Officer of Health for Acton. Real babies are to take the place of dolls as subjects, so that the results of the intended tuition should reach a higher standard of perfection than would be obtainable otherwise.

TUBERCULOSIS IN MIDDLESEX.

At the last meeting of the Middlesex Insurance Committee at Caxton Hall it was stated that the total number of applications for sanatorium benefit already received was 100—78 from men and 22 from women—and that the estimated expenditure in respect of the applications which had been acceded to was about £450.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, NOVEMBER 6TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF OPHTHALMOLOGY) (1 Wimpole Street, W.).—8 p.m. Cases and specimens by Mr. J. Herbert Fisher, Mr. N. Bishop Harman. Papers by Mr. E. Nettleship, Dr. A. Hugh Thompson, Mr. A. W. Ormond, Dr. G. Coats.

MEDICO-LEGAL SOCIETY AND LIFE ASSURANCE MEDICAL OFFICERS' ASSOCIATION (11, Chandos Street, Cavendish Square, W.).—5.30 p.m. Joint meeting to discuss medico-legal problems arising out of the National Insurance Act.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Clinics:—2 p.m.: Throat Operations (Mr. Gillies). 2.30 p.m.: Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. T. Brooks). 3 p.m.: X-Rays (Mr. W. Stewart); Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan). 5.30 p.m.: Eye Operations (Mr. Brooks).

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5.30 p.m. Mr. J. F. Colver: Specimens illustrating Periodontal Disease (Pyorrhoea Alveolaris) as seen in man, wild animals in captivity and domesticated animals. (Museum demonstration.)

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton, S.W.).—4.30 p.m. Sir James K. Fowler, K.C.V.O.: The Symptomatology of Pulmonary Tuberculosis.

THURSDAY, NOVEMBER 7TH.

ROYAL SOCIETY (Burlington House, London, W.).—Mr. L. V.

King, Dr. P. E. Shaw, Mr. E. M. Stubbs and Dr. E. B. R. Prideaux, Mr. C. Smith, Hon. R. J. Strutt, Mr. F. W. Aston, Mr. A. Campbell, Mr. A. Mallock, Sir W. de W. Abney, K.C.B.

ROYAL SOCIETY OF MEDICINE (SECTION OF OBSTETRICS AND GYNÆCOLOGY) (1 Wimpole Street, W.).—8 p.m. Short communications by Dr. Drummond Maxwell, Dr. Russell Andrews, Dr. C. Hubert Roberts. Paper by Dr. J. M. Wyatt: Le Fort's Operation for Prolapse.—Report of Eight Cases.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton, S.W.).—4.30 p.m. Sir William Osler, Bart.: Acute Tuberculous Pneumonia.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5.30 p.m.: Gynaecological operations (Dr. A. E. Giles). Clinics: Medical out-patient (Dr. A. J. Whiting); surgical (Mr. Carson). 3 p.m. Medical in-patient (Dr. G. P. Chappel).

FRIDAY, NOVEMBER 8TH.

ROYAL SOCIETY OF MEDICINE (CLINICAL SECTION) (1 Wimpole Street, W.).—8.30 p.m. Cases by Mr. Donald Armour, Dr. M. A. Cassidy, Dr. J. Galloway, and others.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton, S.W.).—4.30 p.m. Sir T. Clifford Allbutt, K.C.B.: Pleurisy in Relation to Pulmonary Tuberculosis.

MONDAY, NOVEMBER 11TH.

MEDICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—8.30 p.m. Discussion on "Respiratory Neuroses," to be introduced by Dr. Samuel West. The following will also take part in the discussion: Sir David Ferrier, F.R.S., Dr. Risien Russell, Dr. Hector Mackenzie, Dr. Leonard Guthrie, Dr. Farquhar Buzzard and Dr. F. E. Batten.

TUESDAY, NOVEMBER 12TH.

CHELSEA CLINICAL SOCIETY (St. George's Hospital), S.W.).—Meeting 8.30 p.m.: Papers: (1) Dr. Leonard Colebrook, "Pneumothorax Treatment of Phthisis," illustrated by X-ray photos and charts. (2) Dr. David Walsh, "Diseases of the Skin in Relation to Cardio-Vascular Disturbances."

Appointments.

BUSHNELL, FRANK GEORGE, M.D.Lond., D.P.H.Camb., Tuberculosis Officer to the Essex County Council.

COWEN, T. P., M.D.Lond., Medical Officer at Rainhill Asylum.

HUGHES, E. E., F.R.C.S.Eng., Surgical Registrar to the Manchester Royal Infirmary.

KHAN, M. M., M.R.C.S., L.R.C.P.Lond., House Physician at University College Hospital.

LISCOMBE, R. H., M.R.C.S., L.R.C.P.Lond., House Surgeon at University College Hospital.

SCOTT JAMES M., M.B., Ch.B.Glasg., Medical Officer at the Central Branch of the Manchester Royal Infirmary.

Vacancies.

Newcastle-on-Tyne, Dispensary.—Visiting Medical Assistant. Salary £160 per annum. Applications to the Honorary Secretary, Joseph Carr, Chartered Accountant, 26 Mosley Street, Newcastle-upon-Tyne.

Caterham Asylum.—Third Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Applications to the Medical Superintendent, Caterham Asylum, Caterham-Surrey.

Corporation of London.—Medical Officer of Health. Salary £1,000 per annum. Applications to the Town Clerk on or before November 11th. (See advt.)

House of Recovery and Fever Hospital, Dublin.—Resident Medical Officer. Salary £50 per annum, with board. Immediate application to the Medical Superintendent, John Marshall Day. (See advt.)

City of Liverpool Education Committee.—School Medical Officer. Salary £250 per annum. Applications to be forwarded before November 15th to Edward R. Pickmere, Town Clerk and Clerk to the Local Education Authority. (See advt.)

Marriages.

CRUICKSHANK—JENKINS.—On November 2nd, at the church of St. Michael and All Angels, Colombo, Captain James Alexander Cruickshank, I.M.S., son of Dr. Brodie Cruickshank and Mrs. Cruickshank, Maida Place, Nairn, to Dorothea Margaret, only daughter of James Graham Jenkins, J.P., and Mrs. Jenkins, Airedale, Cambuslang, Lanarkshire.

GROGAN—STANLEY.—On October 29th, at St. Gabriel's Church, Warwick Square, Captain John B. Grogan, R.A.M.C., son of Mr. and Mrs. Mulligan, of Courtrai, Belgium, to Betty, daughter of the late Major Edward Stanley, North Stafford Regiment, of Rhoscrowther, Pembrokeshire.

Deaths.

BAGSHAW.—On November 2nd, at 33 Warrior Square, St. Leonards-on-Sea, Frederick Bagshawe, M.D., F.R.C.P., J.P., aged 78.

MAIR.—On November 4th, in London, after an operation, Ludovic William Darra Mair, of Stone Court, Carshalton, M.D., (Lond.), Medical Inspector (Local Government Board), eldest son of Robert Slater Mair, M.D., of 14 Pembridge Villas, W., aged 46.

MORSE.—On October 28th, at Fowey, Sydney Morse, L.R.C.P., L.R.C.S., son of the late A. C. Morse, of Crewkerne, Somerset, aged 54.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX."

VOL. CXLV.

WEDNESDAY, NOVEMBER 13, 1912.

No. 20.

NOTES AND COMMENTS.

The Irish Advisory Committee and the Medical Benefit.

THE fact that Mr. Lloyd George has promised to find more money for the working of the Insurance Act in Great Britain has naturally raised some feeling in Ireland at the unfair treatment to which she is subjected in the matter. It is held that a proportionate sum should be provided for Ireland, and those in favour of medical benefits think that the present is a good opportunity to press for their extension to that country. The Irish Advisory Committee met last week, and adopted a resolution in favour of the extension of the medical benefit. A public agitation to the same effect is being actively organised. The debate at the meeting of the Advisory Committee, which led up to the adoption of the resolution, was of considerable interest. The suggestion was seriously put forward by one friendly society representative that in any extension of the medical benefit to Ireland the dependents of the insured person should be included. In this view he obtained the concurrence of a medical member of the Committee, with regard to whose position and opinions we shall have something to say presently. As no one expects that more money will be available in Ireland than in England it appears obvious that an Irish medical man is expected to attend a family for the same rate as an English medical man is to attend an individual. A further simple solution of the question of the administration of medical benefits was offered. It was that every insured person should be regarded as a "poor person," and, therefore, entitled to medical attendance under the poor law system. The insurance card should take the place of the familiar red or black ticket! The medical profession of Ireland has not as yet expressed its opinion either for or against the medical benefit. If, however, it consents to work the benefit, it must be a genuine system, and not a bastard production, such as was suggested by various members of the Advisory Committee last week, apparently with the consent of some of their medical colleagues.

Medical Members of the Irish Advisory Committee.

It is with considerable regret we find that the Irish Insurance Commissioners have been able to fill the places of those medical members of the Irish Advisory Committee who resigned some months ago as part of the general policy of the British Medical Association. The gentlemen who have now accepted seats apparently think that their individual action is of more importance to the public than would be the united action of the medical profession. The Right Hon. Dr. Cox, one of the original members, is still a member of the Irish Advisory Committee. He took credit at the meeting of the Advisory Committee for the fact that he

had refused the request of the Association to retire from the Committee. It is well to make it quite clear that in no way do these gentlemen represent the opinions or views of the profession. Indeed, when we study Dr. Cox's reported utterances we find him somewhat strong in emphasising his difference from his brethren. He originated the suggestion quoted above, of including dependents in the medical benefit, and this without any additional money being available in Ireland above what may be provided for the rest of the kingdom. In a peculiarly unpleasant phrase, Dr. Cox dissociated himself from the policy decided on by the profession. "For one, his hands were clean and his tongue was clean and his pen was clean in this matter." This can only mean that the policy of his professional brethren is dirty! It is worth while examining whether Dr. Cox has always kept himself so aloof. We understand that he signed the same undertaking as the rest of the profession in Dublin, and that he sent a message to the general meeting of the profession in Dublin, a few weeks ago, regretting his inability to be present. To most people this would appear to show that Dr. Cox was a participator in the general policy of the profession. It is, we think, unfortunate that his dissent should first be made known at a meeting where he is wrongly regarded as representing the medical profession.

Infantile Mortality under the Poor Law.

DR. C. THACKRAY PARSONS, in the current number of *The Poor Law Officers' Journal*, discusses the "uninformed abuse of the Poor Law treatment of children" lately expressed by some members of Bradford City Council.

Dr. Parsons examines the one definite charge—viz., that the infantile death-rate in workhouses is between two and three times as high as in large cities. He points out that the death rates for the first two weeks of life in the workhouse and in the general population can be compared accurately. The Local Government Board has published the figures as regards the Metropolitan Unions for the last two years. In 1910, 2,968 live births took place in the maternity wards of these unions, and 120 of these infants died within two weeks—a death-rate of 40.4 per 1,000. In 1911 there were 2,712 births and 119 deaths—a death-rate of 43.8 per 1,000. The death rate in the general population for these two weeks in 1910 was 29.5 per 1,000 (the figures for 1911 are not yet available), so that the death-rate, instead of being two or three times as much, is really about one-and-a-third as much. Dr. Parsons affirms that the reason for this increase is perfectly obvious to those that know the conditions of the mothers who come to the Poor Law maternity wards for delivery.

A Scientific Study of Fools.

IT is well that society is waking up to the necessity of gauging and standardising the human mind. Those who are interested in this subject—and what medical man is not—should read an interesting article by Edwin Brewster in the November issue of *The World's Work*. Under the title "A Scientific Study of Fools," the conclusions of the French physiologist, Binet, are discussed. As many of our readers probably know, his main practical advance was the Binet-Simon test, whereby he measured the inherent native intelligence, irrespective of the results of training. His tests are so arranged that they demonstrate the degree of mental development arrived at in the individual, for instance, that normal to a child of three, four, six, eight and so on. If the mental development be arrested at three the body goes on growing but the mind is that of an idiot. The child of ten may have the mind of six years; the child of fourteen that of seven or ten; while the grown-up individual never gets any further than the stage of arrest. The tests are most interesting. The average person, upon hearsay, can immediately repeat seven figures, those of extra mental powers eight or even nine. At twelve a child should retain seven figures; at ten, six; below eight, four; at four, three; at three, two.

Oslerising.

THE following simple test is well worth trying. Below seven years a child will not notice that the figure of a lady, otherwise well drawn, lacks arms. Up to eleven he does not cavill at the story that you have locked yourself in your room and could not get out because you left the key on the outside. The practical applications of this new science are likely to be of distinct sociological value. The scientific study of the mind has been formally inaugurated, for the first time in the history of the world, at the training school for backward and feeble-minded children at Vineland, New Jersey, fifty miles south of Philadelphia. It seems that no amount of training develops a mind beyond the stage at which it has become arrested. The average mind appears to have reached the top of its growth at about twenty, or a few years later; good minds go on to forty, the time fixed for the limit in medical men by Professor Osler. Mr. Brewster adopts the term "oslerising" to mark the point of cessation of mental growth. Thus the idiot oslerises at three; the feeble-minded at seven, eight, ten or somewhere short of the normal. He has the body of the adult but the brain of the child. Some of the latter go through life just able to earn a living, but with feeble control over a man's natural impulses.

The Bottom of the Social Problem.

OUT of a group of one hundred juvenile delinquents taken at random, only one was found to be as old in mind as in body—the only normal child in the lot. Six boys of thirteen years tested only nine; twenty-six of fourteen tested only ten; twenty of fourteen tested nine; eighteen of fifteen and sixteen averaged under nine. Such results as these suggest a humane revision of our methods of criminal administration all over the world. One striking case at Vineland was that of a strong, well set up young man of twenty, who led the school orchestra, took part in theatricals, worked in two handicrafts, was a crack athlete, and altogether a pleasing personality. Examination in the laboratory, however, revealed the mind of a boy of thirteen. In the outside world he would be unable to look after himself and would inevitably drift into pauperism or crime. Out of fifty-six way-

ward girls, again, only four were found mentally normal. The name "morose" is applied to the unfortunate individual who has escaped idiocy on the one hand, but whose mental growth has been prematurely arrested on the other. The medical man who carries the main principles of the Binet system in his mind will find plenty of field for their application in practice. We fancy Mr. Brewster is not far wrong in his conclusion that "considering that one sort of brain is always good for a five-figured salary, while another can never earn a living wage, the Binet-Simon scale gets down pretty close to the bottom of the whole economic and social problem."

LEADING ARTICLES.

THE INSURANCE ACT.

AT the present moment the mind of the medical profession remains necessarily for the time being under the influence of that mental perturbation engendered of great issues—namely, a suspended judgment; nor is there much to be gathered from a careful study of sundry stray signs and portents. The medical members of the advisory Committee of the Insurance Commissioners have issued a statement to the profession which may be regarded as representing the cautious and conciliatory side of the case. From an analysis of the financial aspect of the question, they conclude that each medical man will receive £350 for every 1,000 insured persons, in addition to maternity benefit, and a portion of the sixpence set aside to meet extra cost in the matter of drugs. The members of the Committee emphasise their opinion that the doctors must very carefully decide, before refusing to work the Act, whether they are in a position to render the establishment of an efficient State service impossible. They regard the establishment of a uniform £2 income limit throughout the country as impossible, and suggest that the profession should consider how far the point has been met by reference under the Act to the Local Insurance Committees. The document concludes: "We ask you to consider whether, in view of the Government's offer, and in view of their pledge to reconsider the whole question in the light of the facts gathered together during the next three years, the profession would be wise to refuse to work the Act." Whatever may be said in favour of the views of the Advisory Committee, it is evident that they will not be in accord with those of a large number of medical men. From various parts of the country news comes of the rejection of the latest proposals of Mr. Lloyd George. For instance, at a meeting of the Chester and Crewe Division of the British Medical Association, to which all members of the profession were invited, and at which there was a representative attendance, the following resolution was passed unanimously: "That this meeting considers that the conditions of service laid down in the regulations issued by the Insurance Commissioners are intolerable to any self-respecting medical man, and would destroy forever the independence of the medical profession."

We therefore decline to take service under the present regulations." The delegate to the Association was instructed to vote accordingly, and rejection is thereby firmly clinched so far as the Chester and Creve Division are concerned. The Bristol Division of the Association has decided that it is impossible to advise the medical profession to work the Act on the terms outlined in the Chancellor's recent speech. Again, at a largely-attended meeting of members of the Guildford Division of the British Medical Association and others, held at Guildford, it was unanimously resolved that the recommendation of the Provisional Medical Committee that the medical practitioners in the area of the Guildford Division refuse to take service under the Insurance Act be adopted. Other reports to the same effect have come to hand, notably from Manchester, the City of London, and Lincoln, and within the next few days, when the majority of the local Divisions of the Association have registered their decision, it will be possible to forecast with tolerable accuracy the answer of the medical profession. The situation undoubtedly represents the most serious crisis that has ever occurred in the history of the medical profession in the United Kingdom. Amid the turmoil of dispute vital principles are at times apt to escape notice or, at any rate, to receive less than the amount of consideration to which they are entitled. On weighing the point of this complex dispute, one fact which emerges clearly is that much of the present trouble has arisen from the attempt to deprive medical men of control of what they have learned to regard as their own particular business. Matters they have hitherto managed for themselves are handed over to insurance committees composed mainly of laymen. Medical men, if it is true, are permitted to settle disputes arising among themselves, but outside matters of difference must be submitted to bodies which have a lay majority varying from three-fifths to nine-tenths. The climax of lay interference is reached in the proposal to control the professional records and standard of work performed by medical men under the Act. It may be confidently assumed that unless the Chancellor of the Exchequer is prepared once and for all to give up any such proposal he may abandon all hopes of coming to terms with the medical profession. It may be as well to note that the important question of the relation of the medical charities to the Act has not yet been dealt with. Taking all things into consideration, it almost looks as if the latest proposals of the Chancellor of the Exchequer will fail to constitute anything more than a step nearer the long-sought goal of a sound basis of negotiation. Meanwhile we may ask Mr. Lloyd George to consider for a moment what sort of proposals he would be likely to lay before the lawyers were he suddenly to become convinced that sound and cheap law were no less than sound and cheap medicine an imperative necessity for the welfare of fifteen millions or so of his fellow countrymen. Possibly the parallel might conduce to a more practical tempering of expediency with the amenities of a cultured altruism.

CURRENT TOPICS.

Professor Nietner on Tuberculous Infection.

In his address at the recent opening of the new Medical School for Tuberculosis, now established at the City Road Hospital for Diseases of the Chest, Professor Nietner, of Berlin, put forth some observations which, coming from such an authority, claim the most serious attention. He urges that during the last ten years facts have been disclosed going far to establish the conclusion that in a very large majority of cases infection occurs during the first years of life. Hamburger and Schlossmann practically agree that 90 per cent. of all children up to the completed 12th year are infected; that tuberculosis is a true children's disease, is acquired during childhood, and must be prevented, treated, and healed during childhood. Professor Nietner affirms the fact that in by far the greater number of cases the source of infection can be traced to the human subject suffering from "open" tuberculosis, and that infection is acquired through the close intercourse resulting from family life within the home. Only those preventive measures can, therefore, hope for success which keep this fact constantly in mind. But to prevent the child from becoming infected in his home without weakening those family ties which are so essential to the moral health of the nation is a problem of the utmost complexity. Professor Nietner deprecated schemes for separating the child from his family, though every care should be taken to safeguard it in its own home. He denied that tuberculosis was a "school disease," and maintained that the school could not justly be held responsible for the spread of infection. He attached the utmost importance to the careful organisation of the school medical service, and said that to the school doctor alone was the power given to prevent latent tuberculosis developing into active disease in the children examined by him and kept under his supervision.

The Deptford School Clinic.

SOME interesting reading is provided in the third report of the Deptford School Clinic or Health Centre (a), which has now established for itself a permanent footing for the more effective treatment of a large number of children in the district who suffer from want of air and from lack of food. Apart from what are generally known as "Council diseases," the clinic provides treatment for the usual medical and surgical diseases, including skin affections, in addition to minor injuries for which suitable first-aid treatment is dispensed. The founders of the clinic have, from the beginning, been most anxious to interest all parents in the enterprise, and their experience during the past year goes to show that parents are not quite so callous and unconcerned about the health of their children as is sometimes supposed. No less than 6,500 children have received benefit during the last school year, the greater number of cases falling under defects of vision, throat and ear affections and skin diseases. Ethyl chloride has been the anæsthetic of choice for all throat cases, with satisfactory results. The opinion is expressed that the neuroses form a much larger proportion of the cases than the figures would indicate. This is no doubt true, but, at the same time, many organic affections begin as, or are accompanied by, symptoms which are often put down as functional. The average cost per head is not quite three shillings and threepence. As an educational centre in health matters the clinic occupies a prominent position among modern sanitary reforms.

(a) P. S. King and Son, Westminster. Price 3d.

Hereditry and Disease.

AMONG the most interesting speeches in the recent debate on the above subject at the Manchester Pathological Society was that contributed by Professor Hickson. He approached the question from the biological aspect as one ignorant of pathology. He considered that evidence on inheritance in man was often unsatisfactory. The reason seemed to be that man presents many difficulties for investigations. Man differed from all other animals in the extraordinary length of his period of juvenility. Civilised man reached physical maturity at about 15 years of age, mental maturity much later. Man appeared to require for his proper development a long period in which he might be influenced by his environment; he was much more a creature of environment than other animals. It thus became difficult to distinguish between innate and acquired characters. Another difficulty was that man was a very slow breeding animal. It was difficult to get a sufficiently large number of cases of transmission of a particular character. Few statistics included more than three or four generations, or 100 to 150 individuals; in peas or in mice biologists were not satisfied with less than several thousand individuals. There was a third difficulty, not peculiar to man, the possibility of transmission of characters by the placental blood. Such characters were, of course, not innate. This term could only be applied to characters transmitted through the germ cells. For these reasons he was always sceptical of statistics bearing on the transmission of acquired characters. He thought it very doubtful if a hard and fast line could be drawn between fluctuations and mutations. There were, undoubtedly, mutations which were transmitted without blending, but there were others in which there appeared to be only a difficulty of blending. In the case of an extra digit blending could only mean the production of an extra half-digit. Now, experiments on poultry had seemed to show that the transmission of an extra toe obeyed Mendelian laws, but on analysis of the figures it appeared that many of the extra toes were only half-toes, which could equally well be interpreted as blending.

Dust.

NOWADAYS our civilisation has finally got rid of many of the more ponderous evils that used to trouble the hapless race of men. We are still left with the small nuisances that help to make life unbearable. We are safe from being knocked on the head by a peevish neighbour, but to make up for this we are becoming more readily irritated by disturbing details. Noise and dust and such like that our grandfathers would have laughed at, or at the most have hastily objurgated, occupy the attention of our brightest minds. The knowledge that passeth all examinations is giving its utmost attention to nullifying the vexation wrought by the multiplication of small insinuating evils. Dust is well-nigh ubiquitous; competent statisticians have estimated that there are four thousand millions of dust particles in an average puff of cigarette smoke. Chemically pure water is a non-conductor of electricity. The addition of a grain of salt to a hundred tons of water allows the electric current to traverse it. Each molecule of water is linked to its neighbour by a bridge of salt. By such facts as these we realise what is meant by the divisibility of matter. When we realise this and think of all the noxious and nauseating substances of which the dust in our streets is made, we wonder with increasing horror why the chief method of getting rid of dust is to disturb it from its resting place and send it spinning through the air on its maleficent mission.

Dust ceases to be dust when firmly attached to other bodies. A wet duster, tar and crude oils annihilate it. The popular appreciation of this fact would materially reduce the sick rate and the labours of the cleansing department.

A New Cure for Tuberculosis.

IT is quite a little time since we were presented with an infallible specific for the cure of tuberculosis. The latest tilter against Koch's ubiquitous bacillus is Dr. Franz Friedmann, who last week announced the discovery of a cure for all forms of tuberculosis. This comprehensive claim, which is specially stated to include tubercle of the lungs and bones and lupus, was made at a meeting of the Berlin School of Medicine, and under such auspices merits at least our serious attention. 682 patients, including 250 "consumptives," have been treated, and Dr. Friedmann, looking no doubt with the eye of enthusiastic faith, sees "practically a hundred per cent. cures." His method is apparently akin to the treatment of rabies at the Pasteur Institute; as a preparation of living attenuated bacilli is injected intravenously. Over a thousand human subjects are said to have been inoculated with no untoward results. So far the only accounts of Dr. Friedmann's work obtainable are through the lay press, and we are consequently not in a position to deal fully with it. On the face of it, the idea certainly seems worth a trial, but the fiasco of Koch's old tuberculin has made us very sceptical as to the complete efficacy of any new "cure" for the havoc wrought by acid-fast bacilli. A hundred per cent. cures, even when diluted by the blessed word "practically," is too good to be true. For all that, if Dr. Friedmann is demonstrably able to help or relieve even a small proportion of tuberculous cases he will be honoured in his generation.

Depopulation of France.

THIS question has in late years occupied, from time to time, much of our space in editorial and correspondence columns, and it is only a few weeks ago that it was once more discussed in an editorial, suggested by information supplied by our Paris correspondent with regard to a proposed enquiry by the French Government. Our correspondent's news was correct, and it is now announced that a Parliamentary Commission has been appointed. The Government is anxious mainly on the ground of national defence. The French population has for years virtually ceased to increase, whilst the German has been growing at a rate representing the addition of at least an extra army corps annually. When other things are equal victory rests with the big battalions, and France seems now to recognise that without allies she would not be able to hold her own in a fight to a finish with her hereditary foe. The Commission is to examine partially into the social problems involved—infantile mortality, hygiene, intemperance, and tuberculosis, together with questions of assistance to mothers, and of proper education of the sexes. It does not appear that the Commission is to trouble itself with the questions of most interest from the biological point of view, namely, the effect of the extreme limitation of the family upon parents and offspring, and the effects upon the quality of the race which the carrying out of a system of artificial selection on a gigantic scale must surely produce. The broad result of the marriage customs of France is practically to secure a mate for every girl provided with an adequate fortune, however unfit for maternity she is, and to bar the way to marriage for every

other candidate, however rich her physical and mental endowments may be.

Is Insanity Increasing?

FEW medical readers, and, least of all, readers of the *MEDICAL PRESS AND CIRCULAR* can need the suggestion of caution in accepting the statements with regard to the increase of lunacy, so commonly nowadays put forth, sometimes even by men placed, if only by themselves, in the class of specialists in mental disorders. Whenever a cautious and scientific examination of statistics is carried out the evidence goes towards negation of a pessimistic conclusion. This is the effect of the annual report by Dr. J. Carswell, on the certification of lunatics in Glasgow. It includes a review and statistical analysis of the production of insanity during the past twelve years. Dr. Carswell summarises as follows his conclusions:—There has been no increase of insanity among either males or females at the developmental period of life—that is, at age 15-30; there has been no increase among males of any age, but there has been an apparent increase among females at age 25-50. Dr. Carswell believes that the probable explanation of this increase is that public attention having been directed to the better care of mentally defective persons an increased number of females of this class have been sent to asylums. Judged by the "occurrence" test, Dr. Carswell concludes that insanity does not appear to be showing any real increase in Glasgow. Glasgow may be taken as a type of the great cities where all the conditions of life conducive to mental stress exist to the full, and it is not unreasonable to argue from this that similar conclusions would be derived from really scientific examination of the statistics of all our great urban populations.

PERSONAL.

DR. C. S. BREBNER, of Widnes, has been appointed Medical Officer of Health for Chiswick.

DR. MABYN READ has been appointed Whole-Time Medical Officer of Health to the City of Worcester.

DR. T. P. COWEN, M.D.Lond., has been appointed Medical Superintendent of the Rainhill Asylum, Lancashire.

DR. J. LORRAIN SMITH, M.D.Edin., has been appointed Joint Pathologist to the Longmore Hospital for Incurables.

MR. T. B. LAYTON, M.S., F.R.C.S., has been appointed Surgeon to the Throat and Ear Department at Guy's Hospital.

CAPT. K. S. THAKUR, I.M.S., has been selected for appointment as Specialist in Radiography and Electrical Science.

DR. FRANK E. KEANE, M.D., has been appointed Honorary Physician to Out-Patients at St. Vincent's Hospital, Melbourne.

DR. J. I. JAFFE, of Stoke Newington, has been returned unopposed as a member of the Stoke Newington Borough Council.

DR. R. SALTER, of Bermondsey, has been chosen as one of the Labour candidates for the district at the forthcoming election for the London County Council.

DR. DAVID CONNOR KIRKHOPE, M.D.Glas., D.P.II. Cantab., of Leyton, has been appointed Medical Officer of Health and School Medical Officer for Tottenham.

DR. C. ADDISON, M.P., has been presented with an illuminated address by the hawkers of the City of London as an acknowledgment of his services on their behalf.

DR. J. DICKINSON LEIGH, M.D.Edin., F.R.C.S. Edin., D.P.H., has been appointed Whole-Time Medical Officer of Health and School Medical Officer for the Borough of Hartlepool.

DR. HENRY DYER delivered an interesting lecture the other day before the Glasgow Health Culture Society on "Health and Citizenship: The Duties of School Boards and other Public Bodies."

DR. H. J. MACEVOY will preside at the annual dinner of the Harveian Society of London, to be held at the Hotel Great Central, Marylebone Road, N.W., on Thursday, November 14th, at 7 for 7.30.

MR. R. D. O'LEARY, Medical Superintendent of the "Dreadnought" Hospital, Greenwich, was entertained last week at Frascati's by the staff and his colleagues upon the occasion of his departure for the Balkans under the auspices of the Red Cross Society.

DR. R. DUDFIELD, M.A., will read a paper on "Still-Births in relation to Infantile Mortality," at the meeting of the Royal Statistical Society, to be held on Tuesday, November 10th, at 5 p.m., at the rooms of the Royal Society of Arts, John Street, Adelphi, W.C.

DR. THOMAS J. KELLY, of Enniscarthy, has repudiated the statement which appeared in the *Standard* of the 5th instant, of alleged negotiations between him and various Members of Parliament concerning the extension of medical benefits to Ireland. He has had no negotiations with any of the gentlemen named.

PROFESSOR E. II. STARLING, F.R.S., has been appointed Chairman of the Committee on Colour-Blindness and Colour-Blindness of the British Association, the members of which consist of Professors F. Gotch, Leonard Hill, A. W. Porter, and A. D. Waller, with Dr. F. W. Edridge-Green as Secretary.

THE HON. SIR JOHN A. COCKBURN, K.C.M.G., M.D., will preside at a Joint Conference of the Child Study Society of London and the Montessori System of the United Kingdom on the Montessori System of Education, to be held at the Royal Sanitary Institute, 90 Buckingham Palace Road, S.W., on Saturday, November 16th, at 3 p.m.

THE Caimichael Prize for the best Essay on the State of the Medical Profession in Great Britain and Ireland, has been awarded to Mr. H. Nelson Hardy, F.R.C.S.Edin., of Croydon. The writer deals fully with National Insurance, and points out defects in the Irish Dispensary and Workhouse system in Ireland, as well as the one-portal system and other matters of professional interest.

THE following members of the medical profession have been elected or re-elected Mayors of their respective county boroughs: Dr. S. R. Alexander (Faversham); Dr. W. S. Gibb (Hartlepool); Dr. W. B. Maurice (Marlborough); Dr. J. P. Atkinson (Saffron Walden); Dr. E. Cureton (Shrewsbury); Dr. G. W. Jesepe (Warrington); Surg.-Major E. L. McSheehy (Wimbledon); and Dr. J. Rafter (Bootle).

MR. CLINTON THOMAS DENT, F.R.C.S., of Brook Street, W., Chief Surgeon to the Metropolitan Police, formerly Hunterian Professor at the Royal College of Surgeons, a former President of the Alpine Club, who died on August 26th, aged 61, left estate of the gross value of £117,661, of which the net personalty has been sworn at £116,263. He bequeathed £1,500 to the Belgrave Hospital for Children, whom failing to St. George's Hospital, and his medical and surgical works to the Students' Library of St. George's Hospital.

A CLINICAL LECTURE

ON

THE EARLY SYMPTOMS OF TUBERCULOUS MENINGITIS.

By Professor HUTINEL, M.D.,

Of the Faculty of Medicine of Paris; Physician to the Hopital des Enfants Malades.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

The symptoms that usher in an attack of tuberculous meningitis are far from conforming in every instance to the classical descriptions—indeed, the disease often assumes aspects well calculated to deceive and mislead the unwary.

When we get meningeal symptoms in a patient who is known to be suffering from bacillosis, that euphemism for tuberculosis, who, for example, displays well-marked pulmonary, pleural, peritoneal, osseous or intestinal lesions or mediastinal glandular lesions, there is not much danger of our failing to suspect the nature of the morbid process and to formulate an appropriate diagnosis. When, on the contrary, meningitis attacks a person apparently in good health it may tax our diagnostic resources to the utmost.

This is why attempts have been made to distinguish between primary and secondary meningitis. Assuredly it is quite possible for tuberculous meningitis to supervene independently of any pre-existing focus elsewhere, but you must recognise at once that this is quite exceptional. As a matter of fact, tuberculous meningitis is almost always secondary to a latent or known focus of infection. Six or seven times out of ten we find anterior lesions in some other organ or apparatus, and the more carefully we investigate the pathological antecedents of the subjects the more shall we be convinced that primary tuberculous meningitis is of exceedingly rare occurrence. For this reason it is well for us to familiarise ourselves with the prodromata and the initial symptoms other than those which are given in the text-books.

When we are called to a child whose health has hitherto been reputed good, it behoves us to examine into his antecedents as well as those of his parents. Has the father had coxalgia or the mother pleurisy? Has the little patient had enlarged glands or joint troubles? Information of this kind will prove of great service in guiding our enquiry.

We must also investigate recent or distant disturbances of nutrition—i.e., arrest of growth, loss of weight or marked pallor; is there excessive growth of hair at the nape of the neck or in the interscapular region? Then, too, unusual length of silky eyelashes and softness of the flesh are signs not devoid of importance.

If there be wasting with cachexia we may suspect a specific heredity, especially if the child be well fed. If, however, Wassermann's reaction prove negative we must at once suspect the possibility of meningeal tuberculosis at its onset and watch the patient accordingly.

We must not omit to examine the lymphatic glands of the neck, groins and axilla. If we find micro-polyadenitis this would indicate a latent infection, not improbably of tuberculous origin. Lastly, in the absence of any tracheo-bronchial adenitis we must examine the mediastinum for evidence of the presence of germs ready to invade the economy and attack the meninges.

The child suffers more or less from loss of appetite and has a little fever in the evening, with sudden jumps, indicative of some latent infection.

An unequal, unstable, irregular pulse should put us on our guard and direct our attention to the lungs and mediastinum, where bacillary lesions are apt to present themselves.

Interrogation may reveal to us a change in the temper of the little patient who, from good tempered, has become peevish and irritable. We may find, too, that his mental faculties and power of attention have been failing, another sign of incipient invasion of the meninges. Then, too, from time to time the parents may have remarked attacks of headache in their child, coinciding with feverishness. These are the principal prodromata, the discovery of which imposes upon us a certain prudence in the matter of prognosis although they are not, of course, pathognomonic.

And now let us discuss the value of the three great symptoms: headache, vomiting and constipation, which make up what has been termed the "meningitic tripod." At the onset of tuberculous meningitis these are often wanting, while, on the other hand, they are common in connection with other diseases.

In children between three and fifteen years of age, headache is a frequent symptom, but it may be conspicuous by its absence. I remember a case in which, having performed lumbar puncture, I withdrew a liquid rich in lymphocytes and albumen, the presence whereof enabled me to diagnose commencing tuberculous meningitis, yet in this instance there was no headache and typhoid fever was suspected.

In somewhat older children headache is a more constant symptom, but it is frequently absent in infants between six months and two years of age. The same remark applies to spontaneous easy vomiting which is common in the older children, rare in the very young. As for constipation, it may be altogether lacking, or is replaced by diarrhoea.

It is plain, therefore, that these ordinary symptoms of tuberculous meningitis are neither constant nor pathognomonic.

Retraction of the belly, the well-known concave abdomen which is stated to come on early in meningitis may, in some instances, be due to acetonaemic vomiting, which is also accompanied by headache.

In tuberculosis of the meninges dyspeptic disturbances are, as a rule, fairly well marked, the tongue, however, is never dry though furred. It is rare for the fever to rise as high as 104° F.; as a rule it remains somewhere in the neighbourhood of 102°-103° or less. The pulse may be 110-120, and we may note irregularities and intermittences. As to the breathing, we often get either acceleration or slowing. We may find that the diaphragm is contracting while the extrinsic muscles of respiration remain idle, or *vice versa*.

The tuberculous subject at the onset of an attack of meningitis is often depressed and even disagreeable with the persons about him. He insists on being "let alone" and complains of a tired feeling. He lies on one side, curled up, covering his eyes with the bedclothes in consequence of more

or less marked photophobia. He has hallucinations which may be accompanied by a sort of quiet delirium, it is only later that we get the characteristic meningitic scream. Nevertheless, all these symptoms are vague, and present nothing absolutely typical of meningitis; but, as a rule, they "precede and usher in inequality of the pupils, strabismus, palpebral ptosis, stiffness of the neck, and the other unquestionable symptoms indicative of meningeal irritation." The symptomatic tripod may be replaced by attacks of convulsions. For instance, a suckling babe, seven or eight months old, is seized with fits which cannot be accounted for. The fontanelles are bulging, the neck is drawn back, the limbs are rigid, and the belly retracted. The reflexes are dissociated.

As you know, however, fits are not peculiar to infants, they may supervene in older children, but in that case there is a tumour, "a cerebral tuberculoma," which has given rise to secondary meningitis. That was the view expressed by Archaibald, de Rillet and Barthez, which has been erected into a dogma, but which is not without exceptions.

We may meet with slight stiffness of the neck quite at the onset of the disease, long before there is either pain, headache, or Kernig's sign. I remember the case of a little girl in my wards who had been admitted for supposed enterocolitis, in whom, instead of enteritis, we discovered a murmur at the root of the left bronchus indicative of mediastinal adenopathy. One day I happened to caress her in passing, and I noticed that her neck was somewhat retracted. Lumbar puncture was resorted to, when we found that the cerebro-spinal fluid was markedly albuminous and rich in lymphocytes. She died a few days later of tuberculous meningitis, although there had only been constipation, and a temperature of between 102° and 103° F. Here again, however, we must not jump to the conclusion that a moderate rise of temperature and stiffness of the neck necessarily point to meningitis. These symptoms, as a matter of fact, are met with in connection with cervical Pott's disease. They are also present in presence of retro-pharyngeal abscess and cervical glandular abscess. The hypothesis of meningitis consequently can only be seriously entertained after we have excluded all local lesions capable of giving rise to stiffness of the neck. As to Kernig's sign, if it be associated with lymphocytosis of the cerebro-spinal fluid, and changes in the pulse and breathing, then it is really possessed of significance.

When a little patient is brought to us with fever, and he strikes us as rather apathetic, if he suddenly develops facial asymmetry, ptosis, strabismus, inequality of the pupils and hemiplegia, we must entertain the possibility of its being a case of encephalitis, of which these symptoms often herald the onset. We must then look for Babinski's sign, dissociation of the reflexes, and we must not forget to have the cerebro-spinal fluid examined to ascertain whether it is albuminous, and contains an excess of lymphocytes. In very young children, long before we get certain signs of meningitis attention may be attracted to their listlessness, to the fixity of the eyes, to the absence of winking, the bilateral dilatation of the pupils, and especially by a tendency to drowsiness. On enquiry you find that they have been losing weight, the fontanelles are a little tense, the neck a little stiff, and the reflexes dissociated. In such cases we must lose no time in performing lumbar puncture in order to see what the cerebro-spinal fluid looks like. Lastly, there may be some increase of size of the cranium simulating acute hydrocephalus as the prelude of meningitis.

You see, then, that the diagnosis of incipient tuberculous meningitis is sometimes rather difficult, especially in very young infants. We are apt to think of typhoid fever until the stiffness of the neck, the squint, the inequality of the pupils, etc., contradict that diagnosis. We must also be on our guard against mistaking it for a relapse of typhoid fever when three or four months after an attack the subjects develop a high temperature with an irregular pulse, 110 or 120, and retraction of the abdomen. Examination of the cerebro-spinal fluid shows albumen and lymphocytosis, and enables us to recognise the onset of a meningitis which will ere long carry off the patient. In all probability the original attack of supposed typhoid was merely a first outburst of tuberculous.

Enterocolitis must also be excluded. This is how matters stand: A child who has been subject to attacks of enterocolitis is seized with constipation, headache and fever. He is assumed to be suffering from another attack of enterocolitis, and no anxiety is felt, but a fortnight later the little patient succumbs to meningitic troubles.

Not long since I saw a child who, for the fourth or fifth time, presented signs of appendicitis with constipation, abdominal pain, vomiting and fever. The physician called in a surgeon who, struck by the curious aspect of the little patient, examined him closely, and discovered strabismus and inequality of the pupils. I was then called in, and confirmed the existence of Kernig's sign, stiffness of the neck and marked inequality of the pupils. This turned out to be a case of tuberculous meningitis.

A little girl, suffering from slight cervical adenitis, complained of disturbances of vision. An oculist was called in and diagnosed tuberculosis of the choroid. Soon after she died of tuberculous meningitis.

I need not insist upon the mistakes that are made at the onset of tuberculous meningitis, and I only hope that this long enumeration of the difficulties that arise in this connection will impress upon you the importance of lumbar puncture directly you have the slightest suspicion of the nature of the troubles.

In these cases the cerebro-spinal fluid may be under pressure, already a sign of some value. As a rule, the fluid is clear, presenting at the bottom of the test-tube a cloud formed apparently of threads of cotton. In rare cases it is coloured, tinted with blood due to minute hæmorrhages in the brain. It is of higher specific gravity, and it contains coagulable albumen twice or three times the normal amount.

Cytological investigation shows pronounced lymphocytosis, and polynuclear cells may be present; but if we puncture several times these disappear, the lymphocytes remaining. This polynucleosis may possibly be due to some concomitant secondary infection; but in the centrifugal clot we may find tubercle bacilli. Guinea-pigs inoculated therewith die in the course of a few weeks.

In doubtful cases lumbar puncture will settle the question; nevertheless, you are not entitled to insist upon it, seeing that it is in no sense curative, and is often objected to by the family.

I may add, in conclusion, that in tuberculous meningitis we sometimes get remissions which you must be careful not to mistake for recovery. In 1874, when I was house-physician, I saw a little girl nine years of age who was hemiplegic and meningitic. She recovered from her cerebral affection only to die twenty-five years later of tuberculous meningitis. Long remissions are, therefore, possible, but are extremely rare.

NOTE.—A *Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Edward C. Hort, F.R.C.P.Ed. Subject: "The Causes and Treatment of Fevers."*

ORIGINAL PAPERS.

A NOTE ON INJURIES AT OR NEAR THE ANKLE. (a)

PART II.

By J. JACKSON CLARKE, M.B.LOND.,
F.R.C.S.

Senior Surgeon to the Hampstead and North-West London Hospital and Surgeon to the Royal National Orthopaedic Hospital.

RADIOGRAPHY more than any other agency has developed knowledge of the varied forms of injury that affect the posterior part of the tarsus, and the close investigation of the effects of injuries demanded by the Workmen's Compensation Act has shown the great importance of early and complete diagnosis of such injuries. It is therefore important to know all the different injuries and the commoner combinations of them.

The different groups of injuries will be numbered as in the list given in the first part of this article published in the issue of this Journal of the 6th of November. In *Clinical Examination* Destot recommends that a tracing of the inner border of the foot, the ankle being at a right angle, be made. The breadth of the inner border of the foot is increased in both astragalo-scapoid and in medio-tarsal lesions.

Radiographic Examination.—In examining skiagrams the astragalo-calcaneal shadow must first be examined; in astragalo-scapoid lesions the head of the astragalus is depressed; in transverse tarsal displacements the internal column, the scaphoid with cuneiform bones, are thrown upon the dorsum of the foot. Both lesions give rise to apparent flat-foot, as do fractures of the os calcis—e.g., by sinking of the astragalus into the thalamus, or by elevation of the tuberosity.

If astragalo-scapoid cases are left to themselves the resulting flat-foot is painful.

In both cases there is deformation in the long axis of the foot; when the feet are brought together the heels and the heads of the first metatarsal bones cannot be approximated at the same time.

In interpreting skiagrams in cases of injury, or alleged injury of the posterior tarsus, the changes produced by common static flat-foot and the deformities produced by *arthritis deformans* and *tabes dorsalis* must be borne in mind. The mechanical conditions represented in Figs. 1 and 2 and the modifications which hold good in different positions of the foot must also be borne in mind.

Fig. 3 is the tracing of an extreme case of spontaneous flat-foot, and it would do equally well for a sub-astragalar dislocation of the foot outwards; or another way of expressing the same fact: incomplete dislocation of the astragalus inwards. This instance alone shows the great care required in diagnosis in cases of alleged injury. We may now pass to consider the remaining groups of injuries.

Group 6.—Fractures and Dislocations of the Astragalus.—Taking an astragalus in the hand one notes the groove of the trochlea corresponding to a smooth elevation of the tibia and on the under aspect the depression for the attachment of the interosseous ligament one infers that a longitudinal splitting would be a common fracture. Such a fracture (b) I described as follows:—A right

astragalus. A fracture which passes in a plane oblique from before backwards and outwards, has separated the inner part from the rest of the bone; the inner fragment is sub-divided into four sub-equal portions. From a man who fell about six feet from a scaffolding. The greater part of the

FIG. 1.—The outline of the bones traced from a skiagram of a normal foot is shown.

bone could be seen and felt beneath the skin in front of the ankle. Astragalectomy was performed. The outer fragment was found to be separated from all its attachments, and rotated, so that its upper surface was directed inwards.

FIG. 2.—Is the same figure with the addition of a vertical line, 1, to represent the chief line of transmission of force from the tibia to the highest point of the astragalus when the foot is at right angles with the leg. The small circle shows the centre of rotation at the ankle and it lies on the external process of the astragalus in front of the chief line of force. The thick ruled lines represent the inclination of the body of the astragalus to its neck, and the direction of the bony trabeculae from the posterior astragalo-calcaneal articulation to the heel and the inclination of the greater process to this. The posterior process of the tibia is shown at 3 and the mechanical anterior border of the tibia is indicated at 4.

(a) The Figs. in this article are tracings from skiagrams, and, with the exception of Figs. 3 and 7, are after Destot.

(b) "Catalogue of St. Mary's Hospital Museum," 1897.

Separation of minute fragments of the astragalus is observed in cases of sprain and in dislocations. Such small fractures are not so rare as they were formerly thought to be. They tend to delay recovery, and may cause permanent stiffness. Surgically fractures of the astragalus are more important than fractures of the os calcis, because they afford more scope for treatment.

FIG. 3.—Tracing from the skiagram of an extreme degree of spontaneous flat-foot.

It is not always easy to distinguish either clinically or by radiography between a fracture of the body and one of the neck of the astragalus. The body of the bone includes the tibial and the postero-external calcaneal surfaces, and joins the neck in an oblique plane. In lateral skiagrams the shadow of the internal malleolus falls in front of the anterior border of the body of the astragalus and is apt to be mistaken for it.

Fractures of the astragalus may be associated
 (a) With fracture of the inferior tibial surface;
 (b) With fracture of the calcaneum;
 (c) With fracture of the scaphoid.

Isolated fractures are sub-divided into:

- (a) Fractures of the body, e.g., Fig. 4.
- (b) Fractures of the neck, e.g., Fig. 5.
- (c) Fractures of the head.

Injuries to the head of the bone are best considered with fractures of the scaphoid. All classes include cases with and cases without displacement, the latter having become known since Röntgen's discovery.

FIG. 4.—Fracture of the body of the astragalus without displacement.

Class (a).—Fracture of the body of the astragalus is a serious injury, demanding removal of the whole of the bone. Partial resections are useless. In the impacted variety the body of the astragalus is converted into a pulp, and the part is fixed in the position it occupied at the moment the damage was done.

Class (c).—A fragment of the head of the bone can sometimes be felt displaced under the skin of the dorsum of the foot. In cases where there has been no direct injury to guide the surgeon, the diagnosis is often made only when, owing to the subsequent development of a painful flat-foot, an X-ray is taken.

Class (b).—The neck of the astragalus has the function of transmitting the weight of the body in the digitigrade position of the foot. Fissures extending to the body of the bone may complicate fracture of the neck as mentioned above.

FIG. 5.—Fracture of the neck of the astragalus, the hinder fragment being displaced backwards.

Complete dislocations of the astragalus apart from fractures are rare, but this bone has been known to be completely separated from the body, being shot through an aperture in the skin by the dislocating force. The astragalus, writes Destot, is a badly nourished bone, and when there is a double displacement it is best to resect it.

Astragalectomy for dislocation of the astragalus was practised in the year 1818 by Dupuytren, who relates the case of a coach-builder who, on leaping backwards from a ladder, sustained a forward dislocation of the astragalus:—Excruciating pain, a large, hard, irreducible prominence beneath the skin, in front of the tibia and fibula, and extending to the instep, much extravasation of blood and a "frightful amount of swelling, which increased every moment and seemed to threaten speedy gangrene."

An incision was made through the skin parallel to the axis of the foot, and the head and neck of the astragalus were immediately brought into view. They were seized, but in vain; for the posterior part of the bone was grasped and held fast between the tibia and os calcis. It was found that the astragalus was inverted and the hook-like process at its posterior extremity was firmly fixed beneath the tibia. "I now fastened a piece of strong twine round the neck of the displaced bone, and, by forcibly elevating it, was enabled to disengage it from its locked position and remove it entire with the exception of a small fragment, which was subsequently discharged. I saw M. G. three years after this occurrence, when he walked with some slight degree of lameness, but otherwise as quickly and for as long a distance as before the accident"—and this happy issue occurred in spite of suppuration and constitutional disturbance usual after open operations at that time.

Group 7.—Fractures of the Os Calcis.—Class

(a): Fracture by avulsion of the posterior extremity by traction of the tendo Achillis; this fracture, Fig. 6, is very rare, and requires open operation.

Class (b): Fractures by the weight of the body falling on the feet. It is to be observed that although the os calcis comes almost in contact with the ground, the common fractures it sustains are indirect.

1.—Fractures of the middle portion—the body (a) of the bone, or *thalamus*. This fracture is an impaction of the posterior astragalo-calcaneal articular surface in varying degrees (see Fig. 7). This is the commonest fracture, according to Destot.

2.—Fracture between the body and anterior extremity, or the greater process.

3.—Fracture of the tuberosity.

4.—Fracture of the sustentaculum tali is rare and usually accompanied by fracture of the external malleolus. An erroneous diagnosis of bi-malleolar fracture may be made, and surprise is felt that a patient with such a common injury does not get well. A tender, bony mass forms below the internal malleolus. The X-ray shows a dark line crossing the anterior end of the bone and the lower part of the head of the astragalus—the latter is tilted downwards.

The following points in diagnosis and treatment may be noted.

Fracture of the greater tuberosity of the os calcis may be (a) partial by avulsion of the part to which the tendon of Achilles is attached (Boyer's fracture, Fig. 6); or (b) total. Thickening of the heel, fol-

FIG. 6.—Avulsion of the hinder extremity of the os calcis—Boyer's fracture.

lowed by rapid swelling and ecchymosis, ensue. When the swelling has subsided, the sub-malleolar depressions are found to be normal, or only a little fuller than usual. The foot-print is thickened along its outer part, but the arch is not flattened as much as in fracture of the thalamus; the fore part of the os calcis is intact. This variety is important owing to the fact that the prognosis is favourable, because the surfaces on which the astragalus rests are intact.

The treatment of fractures of the calcaneum, save for fixation of the fragment in Boyer's fracture by open operation is nil, but X-ray diagnosis is important because the prognosis is very different in different cases, though clinically cases may closely resemble one another.

(a) The body or thalamus of the os calcis is not described in some standard works on anatomy; an omission that is felt in considering fractures of this bone.

Group 8.—*Sub-astragalar sprain and sub-astragalar dislocation*.—*Sub-astragalar sprain*.—In order to produce this sprain, the astragalus must "tack, roll and pitch" in its calcaneo-scapoid bed, and the triple movement is accompanied by rupture of ligamentous fibres, except the interosseous ligament, which remains intact as a rule. Sub-astragalar sprain is the result of a temporary dis-

FIG. 7.—Diagram showing fracture of the thalamus of the third degree with total fracture of the tuberosity and of the greater process. The peculiar kind of flat-foot differing from the ordinary kind (Fig. 3), and also the diminished distance from ankle to the under surface, is to be noted.

location. The symptoms are (a) swelling localised to the sub-astragalar region, and (b) ecchymosis. It is sometimes mistaken for fracture of the external malleolus, or avulsion of its tip.

X-rays may show particles of bone separated from the head of the astragalus or from the scaphoid; prognosis must then be guarded. Diastasis of the inferior tibio-fibular joint may be present without displacement. This sprain is a common one, and may be looked upon as an incomplete sub-astragalar dislocation which has been reduced spontaneously.

Sub-astragalar dislocations are usually characterised by being produced without much violence, slipping from carriages, bicycles, etc. They cause relatively little pain, and are easily reduced. The necessary anatomical condition for a sub-astragalar dislocation of the foot is rupture of the interosseous ligament. Three forms of the displacement occur:—

Form i. The head of the astragalus is displaced upwards and inwards. This form may be caused by a relatively slight injury, such as a false step. The condition which precedes the rupture of the ligament, according to Destot, appears to be a forced plantar flexion at the transverse tarsal joint, opening the bed of the astragalus, the head of which rests between the anterior border of the tibia and the upper border of the scaphoid, thus causing more or less equinus with an increase of depth of the foot below the malleoli. The head of the astragalus is easily felt beneath the skin, which is so much stretched that it tends to ulcerate. This condition recalls that seen after fracture of the astragalus with displacement of the fragments, but in the sub-astragalar displacement the foot is abnormally rigid instead of being abnormally flexible; the force causing the displacement, and the resulting pain are both less in cases of sub-astragalar dislocation than in those of fracture. Reduction under anaesthesia is easily,

the body the internal saphenous vein in front of the internal malleolus is most convenient. In ten of my cases it was chosen. In one instance no adequate vein was found. This patient was an emaciated girl, fourteen years of age, and as the operation was amputation of the leg it was considered advisable after failing to get a vein in the arm to resort to ether.

During induction the fluid is run in at a rate of 50 to 150 cc. a minute. While less is needed, the more rapid the flow, I have found it advisable in the case of feeble patients to slow the infusion to 40 or even 20 cc. a minute, to avoid marked depression of the respiratory centre. In two or three minutes the patient becomes drowsy and yawns with subjective sensations of warmth and well-being. This drowsiness merges rapidly into deep sleep, the conjunctival reflex goes, and a little later the corneal reflex is lost. A minute later the operation may be started. Usually the induction is unaccompanied by any struggling whatever, only one of my patients proving troublesome. This patient was sent up from the country for emergency operation of amputation of a crushed hand. He arrived at hospital prepared for operation as in the pre-anæsthetic days.

As has been mentioned, the danger during induction is marked respiratory depression, which causes cyanosis. This is immediately checked by slowing the infusion. Normally, the breathing becomes quiet, so that special pains should be taken to keep the tongue forward.

In two of these cases slight cyanosis, due to an overdose of anæsthetic, developed, but was immediately relieved by diminishing the drug. A little oxygen was also given as it was ready, but I do not think it was necessary. Both of these patients were carcinomatous, one being a woman of 50 and the other a man of 78.

The time of induction has varied from six to fifteen minutes, and the amount of solution from 250 cc. to 1,250 cc. The latter dose was necessary in a strongly-built man of 30, though given at a rate of 130 cc. per minute, while the former was sufficient for a man of 78, though given at a rate of only 20 cc. per minute. Once the skin incision is made the flow is cut down so as to keep up anæsthesia with as little fluid as possible. The patient is well asleep when the corneal reflex is gone; the pupil is one to two mm. in size and reacts to light. On relaxing the anæsthesia, the pupil enlarges and the corneal reflex returns. The oxygenation of the face and ears should always be good.

On beginning the infusion the pulse rate increases to about 120 per minute and then falls in a few minutes to about 80. The subsequent regularity of the pulse is remarkable, and is due, I think, to the constant infusion. For example, at the commencement of an amputation of the breast for cancer in a woman of 45 the pulse was 80, while on leaving the table 65 minutes later it was 72. In only four cases was the pulse rate more than 100 after operation, and in all these the hæmorrhage had been exceptionally severe.

A few minutes before the end of the operation the anæsthetic is stopped, and, as a rule, the corneal reflex has returned before removal of the patient from the theatre. The period of sleep afterwards varied from half-an-hour to, in one case, 18 hours. In about 24 cases the patient spoke within two hours and soon fell asleep again to wake occasionally throughout the night. That is to say, in no case suitable for the anæsthetic was there anything like prolonged unconsciousness. Drowsiness, however, persists for 24 hours.

For five patients of the series morphia was required; of these three had undergone bone opera-

tions. Only three patients vomited after operation, one of whom had stones removed from the common bile-duct while the other two were suffering from intestinal obstruction. Finally one patient had slight headache for 24 hours but did not volunteer the information herself.

Retention of urine occurred after hernia operations, as with ether anæsthesia, but was never prolonged. In no case was there suppression of urine, glycosuria, or albuminuria.

On leaving a catheter in the bladder during operation it was found that in the third stage of anæsthesia no urine was secreted, a phenomenon which also occurs during the administration of ether and chloroform.

The blood pressure records of this series are, unfortunately, very incomplete, but, so far as they go, bear out Mr. Page's results. A fall in pressure of about 20 mm. of mercury occurs at first, after which the pressure remains constant.

The total amount of the drug given must vary greatly according to the age and condition of the patient and the nature of the operation. An arbitrary maximum is 2,000 cc., or about 66 oz. but it is only under exceptional circumstances that so much should be given. My fourth case received 2,020 cc., but, as the operation was the removal of a large epithelioma of the scalp and grafting of the exposed area, this great amount of fluid had no deleterious effect whatever. In fact, it no more than compensated for the hæmorrhage. On the other hand, the introduction of a large quantity of fluid into the circulation of a patient who does not need it, is a dangerous procedure and is responsible for most of the complications which have recently been classified by Dr. Veale, of Leeds, under the headings—cutaneous, pulmonary, and venous, complications. Under the first head are mentioned—patches of œdema in the gluteal region, blisters on the heels, and bedsores. None of these have occurred in my series, but they should be guarded against by giving instructions to the nurse in charge to change the position of the patient while asleep. With regard to pulmonary trouble, it must be stated that this anæsthetic is distinctly contra-indicated in the case of young robust people, who are undergoing operations of moderate severity unaccompanied by serious loss of blood. Such patients invariably require up to, and over, 1,200 cc. for a operation lasting half-an-hour, and are therefore peculiarly liable to develop œdema of the lungs. On the 10th of this month I anæsthetised J. F., a boy of 17, for the cure of an inguinal hernia. The anæsthetic was taken well, but had to be infused rapidly. In all 1,250 cc. were used. On return to bed at 12 noon his corneal reflex was very sluggish, and he was still unconscious. An hour later he was not completely anæsthetic. Towards five o'clock his breathing quickened, his temperature rose, and he became slightly cyanotic. I saw him at six, when the respirations were 40, the pulse 144, and the temperature 101.4° F. His face was flushed and wet with perspiration. The corneal reflex was gone, but he still moved slightly when stimulated. A catheter was passed and 20 oz. of urine withdrawn. He was propped up in bed, the tongue was drawn forward and some frothy mucus removed from the mouth. One bag of oxygen was administered, and in fifteen minutes his breathing had slowed to 30 and his pulse to 108, while the corneal reflex had returned, and he moved briskly when stimulated. During the night he remained in the same condition, and mucus was sucked out of the larynx at 1 a.m. Towards morning he steadily improved and awoke at 6 a.m., eighteen hours after the operation. He made an uneventful recovery. In such cases the indication is to open a vein and with-

draw about 10 oz. of blood, if the symptoms do not improve on clearing the air passages.

Bronchitis is the second lung complication that may occur. In this series two patients developed a cough that lasted about 24 hours. As one of them had only 550 cc. infused, it was probably in this case due to a chill rather than the anæsthetic. In a third case, a woman of 35, suffering from gall stones, a small patch of broncho-pneumonia developed in the right apex. She recovered from this, however, in a few days. As she was in feeble health, and only required 750 cc. of solution, I do not think it is likely that the anæsthetic was at fault. Nevertheless, pneumonia is a definite, though very infrequent complication, and has been responsible for three reported deaths.

Of the occurrence of infarct from a dislodged thrombus I have no experience. It could hardly happen unless the vein were infected, and only one case is reported in which it probably occurred. Thrombosis of the femoral vein has not been found in any of my cases, and in the five cases reported by Dr. Veale it has not been proved that the method of anæsthesia used was responsible. We have had no case of cerebral thrombosis, and one alone has been reported.

In concluding a discussion of the possible complications of this anæsthetic it is desirable to mention the more severe operations performed with its assistance.

The series includes, excision of the lower jaw for cancer, excision of epithelioma of the scalp, excision of carcinomatous glands in the neck, amputation of the breast for cancer, gastro-enterostomy for advanced pyloric cancer, two colostomies for rectal cancer, laparotomy for obstruction, two appendicectomies, cholecystotomy, choledochotomy, two amputations, cerebellar decompression and cranioplasty. The ages of the patients vary from 17 to 78 years and the duration of anæsthesia from 10 minutes to 1 hour 53 minutes.

Already some of the disadvantages of this method have been mentioned. First is the occasional difficulty in finding a suitable vein. In the case of one patient the cannula was introduced into a vein so small that the infusion was delayed, and consequently anæsthesia was not obtained until twenty minutes had elapsed. Secondly, the absolute necessity for asepsis renders the method unsuitable outside the hospital theatre; while, thirdly, it is unnecessarily complicated for short operations. On the other hand, in operations on the head and neck the surgeon is not hampered by the anæsthetist in the least degree, oozing from the skull and dura mater is remarkably slight, and in abdominal operations muscular rigidity is entirely absent. Neither of these points has, I think, been sufficiently emphasised. With any other anæsthetic the greatest danger in brain work is hæmorrhage; in abdominal work the operation is often delayed, and correct *technique* rendered impossible through rigidity of the muscles. With hedonal both of these undesirable factors are practically eliminated. Moreover, in cases of hæmorrhage and collapse the constant infusion of saline is useful, while if more saline be needed the tube can be removed from the container and a further infusion of ordinary saline given. This was done in two of these cases with distinct benefit.

From the occurrence of œdema in a youthful patient, which I have described, and from exactly similar accounts mentioned in the journals, it may be fairly argued that the anæsthetic is contra-indicated in the young and vigorous, who are to undergo slight operations. On account of the possibility of such a complication, I would endeavour in all such patients, if the anæsthetic were desirable for other reasons, to lessen the amount of infusion

necessary by administering, two hours before operation, two to four grammes of hedonal by the mouth, as recommended by Mr. Page.

With regard to the contra-indications, it is impossible to speak authoritatively, except to mention that, as the laryngeal reflex is abolished very early and completely, a tracheotomy must be performed and the pharynx plugged before an operation on the mouth, nose, or neighbouring air sinuses is attempted. This precaution was observed in the removal of the lower jaw and part of the tongue, mentioned already, and the results were excellent. Slight cyanosis occurred on introduction of the tube, but was due to blood clot in the tube and was immediately relieved on removal of the clot.

In cases of uncompensated heart disease, the infused liquid might throw a dangerous strain on the right ventricle, but I have no definite information on this question. On the other hand, nephritic patients prove good subjects, and so far no cases of suppression are recorded. This is due to the distinct diuretic effect of the saline infused. In six severe cases the average amount of urine passed in the twenty-four hours after operation was 900 cc. Also, as has been shown, the amount of nitrogen to be excreted is extremely small, so that the absence of kidney complication which obtains is only what might be expected. In this series no death occurred which can be attributed to the anæsthetic. Three patients died while in hospital, the first of whom was suffering from left-sided hemiplegia. She was almost comatose before operation, being only able to move the right arm and leg feebly when stimulated. In the whole course of the operation, which lasted one hour and three-quarters, only 300 cc. were injected, and on leaving the table the patient was no more comatose than before. Death occurred eighteen hours later, and it was found on examination that she was suffering from vegetations on the aortic valves, long-standing infarcts in the kidneys, spleen and liver, and finally a relatively large aneurysm in the right internal capsule, which caused the hemiplegia.

The second death occurred in a boy of 18 years, who came to hospital with a history of three weeks of severe vomiting and partial obstruction. He was operated on at once, and laparotomy confirmed the diagnosis of pelvic sarcoma. His recovery from the anæsthetic took place within an hour, but he died the following evening. The *post-mortem* examination showed a huge sarcoma infiltrating the pelvic wall and pressing severely on the rectum.

The third patient was a man of 71, who came to hospital suffering from prostatic retention. He had been tapped six times suprapubically during the previous week, and was in a very feeble condition. The urine was very foul. A suprapubic cystotomy was done to drain the bladder and the prostate was removed. The operation lasted six minutes, and the amount of hedonal used was 500 cc., but he died two days later. *Post-mortem* the only cause of death found was pelvic peritonitis, a condition, it may be assumed, due to infection when the bladder was being tapped.

In conclusion, my thanks are due to those surgeons who allowed me to anæsthetise their patients, and, more especially, to Sir Thomas Myles, whose cases constitute the majority of this series.

Gift to a Manchester Hospital.

MR. EDWARD GRAHAM WOOD, of Manchester and Salford, has presented a cheque for £1,000 to endow a bed at St. Mary's Hospital for Women and Children, Manchester. Mr. Wood has helped to raise £50,000 for the same hospital, and this is the fourth bed he has endowed in the district.

THE ARTIFICIAL PRODUCTION OF PNEUMOTHORAX IN PHTHISIS BY INJECTION OF NITROGEN (a)

By HUBERT CHITTY, M.B., M.S., F.R.C.S.

I FEEL somewhat diffident in writing on a subject of which my own experience is very slight. Thanks to the courtesy of Dr. Campbell-Faill, (b) I am at the present moment treating several patients in conjunction with him, but we commenced our treatment so recently that it would be unfair to draw any conclusions from them as to what the end results may be. The subject has, however, been much before the medical profession of late, and I hope it may serve a useful purpose to summarise the results which others have obtained by this method of treatment.

During the past hundred years it seems to have occurred to a good number of observers that the course of pulmonary tuberculosis might be favourably influenced by mechanical means. Spasmodic attempts have been made to limit the movements of the lungs by strapping the chest, or by compressing it by weights. Of recent years, too, operations have been performed upon the bony chest wall in order to favour the collapse of tuberculous cavities. Other operations have been undertaken with the idea of draining these cavities, or of removing the whole or part of a tuberculous lung. The results of these last procedures have generally proved fatal.

Forlanini noticed that quite a number of cases are on record in which the arrest of pulmonary tuberculosis has coincided with the development of a pleural effusion, and this observation led him (in 1882) to suggest that the induction of an artificial pneumothorax might exercise a beneficial effect on the course of this disease. He himself has reported many cases successfully treated in this way, and the method is being extensively carried out on the Continent and in America. In all upwards of four hundred cases have been recorded.

Several observers have practised this operation in Great Britain, but it is only since Dr. Lillingston summarised the treatment and its results, in an article in the *Lancet* (1911, ii., 145) last year, that any general interest has been taken in it by the medical profession of this country.

Let us consider the rationale of the proceeding. We know how important a part rest plays in the cure of tuberculosis in other parts of the body. Now it is obvious that if a satisfactory pneumothorax can be produced, the lung on that side will be absolutely immobilised. In addition to this, however, any tuberculous cavities will be encouraged to collapse, and their contents will be expressed. Every doctor knows how essential is free drainage to the cure of an abscess in other parts of the body, and it is only reasonable to suppose that the same principle holds good in the case of the lung. A tuberculous cavity cannot be expected to close all the while it is held open by its attachment to the rigid chest wall, and is distended by purulent material which cannot drain away.

Now, what one sees when a pneumothorax is induced is as follows:—During the first few hours the amount of expectoration is greatly increased as the lung empties itself of its retained secretions, and the temperature may rise at this period. Afterwards the temperature falls to normal, the cough diminishes, and the patient soon experiences a distinct feeling of improvement.

One knows how exercise, excitement, or an exacerbation of the cough will send up a tuber-

culous patient's temperature, or produce marked fluctuations in the opsonic index. Presumably this is by causing the absorption of large doses of bacterial products from the diseased lung. By the induction of a pneumothorax we put the lung at rest and diminish the amount of blood circulating through it, and, as a natural consequence, we find a steadying of both temperature and opsonic index. This must be of great importance if we wish to treat the patient successfully by tuberculin injections. The pulse follows the temperature. In one of our cases it fell from 120 on the morning of the first injection of gas to 80 two days later.

Before describing the operation I will enumerate the principal dangers. You will thus be able to appreciate how all, or almost all, of these may be obviated by careful attention to details of *technique*. Briefly, then, the chief dangers are:—

(1) Pleural reflex, *i.e.* shock, or even sudden death due to tampering with the pleura. Though this disaster is fortunately extremely rare, yet it may occur, just as it may when one taps a chest for pleurisy, or washes out an empyema cavity.

(2) Gas embolism, from the injection of gas into a vein, instead of into the pleural cavity.

(3) Asphyxia.

(4) Infection, with the production of a pyopneumothorax.

Of the minor complications, faintness during the gas injection, or shortly afterwards, is not uncommon. Dyspnoea is the rule when a positive intrathoracic pressure has been established. Slight temporary dysphagia has been recorded. Pleural effusion occurs during the course of treatment in 30 per cent. of all cases. One need rarely interfere, but may aspirate and replace by gas if it is causing any unpleasant subjective sensations. Surgical emphysema when it occurs subsides without treatment. It may be prevented by strapping a pad over the site of the puncture.

The apparatus consists essentially of:—

(1) A bottle containing nitrogen.

(2) A hand bellows connected with

(3) A second bottle filled with water. This water can be forced by the bellows into the first bottle, displacing an equal volume of nitrogen. Both bottles are graduated.

(4) A delivery tube which leads from the nitrogen bottle and is connected by a Y piece with a water or mercury manometer. The gas may be passed through a warming coil if desired.

(5) A needle, of which there are several forms. The commonest pattern in use is that designed by Saugmann.

Operation.

A preliminary injection of morphia or hyoscine lessens the tendency to pleural reflex and shock. I need scarcely mention that the patient's skin, the needle and the operator's hands must be carefully sterilised, as faulty asepsis may lead to a fatal result. The needle is pushed into an intercostal space till it is felt to penetrate the pleura. The point selected will be as far as possible from the chief seat of the disease, and more than one puncture may have to be made before a spot is found free from adhesions. In quite a large percentage of cases no such spot has been discovered, and consequently failure to produce a pneumothorax at all has resulted. It is well to anaesthetise the skin before the initial puncture is made. Brauer dissects down to the pleura by open operation, so as to make certain that the point of the needle is actually introduced between its two layers. He is thus enabled to use considerable force to break down adhesions, and he records remarkably few failures. The needle is connected with

(a) Read at a meeting of the Bristol Medico-Chirurgical Society held on May 8th, 1912.

(b) Of the Bristol Dispensary for the Prevention of Tuberculosis.

a manometer, and when one thinks the needle point is in the pleural cavity the manometer is read. If good oscillations are shown (Lillingston mentions —14cm. of water on inspiration, to —6cm. during expiration as an average reading) there can be no doubt that the needle has in fact entered the pleural cavity. Small negative oscillations round about —4cm. of water indicate that the lung has been punctured. If the reading is not satisfactory one of three things has happened: (1) the needle is not between the two pleural layers, (2) these layers are adherent, or (3) the needle is blocked. Under these circumstances it is inadvisable to proceed, for the needle may have punctured a vein, and then there will be the danger of causing gas embolism. To minimise this risk I use an ordinary trocar and cannula for the first puncture. Then, removing the trocar, I introduce an inner cannula which has a solid end and a lateral opening, and which projects a short distance beyond the end of the outer cannula. It is practically impossible for this to get blocked, or for it to enter a vein, and this procedure combines the safety of Brauer's method with the simplicity of Saugmann's. Once a pneumothorax has been produced I employ a Saugmann's needle to maintain the condition. Being certain that the needle is in position, proceed slowly to pump in gas. Nitrogen is generally used, for it is not absorbed so quickly as is air. As the gas is introduced a careful watch must be kept on the patient, and if he manifests any unfavourable symptoms a stop should at once be made. At the end of the first injection the pressure is as a rule still negative, but where there are many adhesions the injection of even a few hundred c.c. of gas may cause the pressure to become positive. The initial pressure should not be raised above 4cm. of water, and except in the case of a partial pneumothorax, in which it is desired to break down adhesions, at no time should it be raised above 10cm. of water. Probably not more than a half to one litre should be injected at the first sitting, though on subsequent occasions the amount may be increased if this does not seem to be causing distress. The effects of large injections and high pressures may be alarming. Pain may be caused by the tearing down of adhesions; dyspnoea from the mediastinum being pushed over, thus hampering the action of the opposite lung; asphyxia caused by the secretions of the diseased lung being emptied into the trachea, and aspirated into the sound lung. After the initial injection the process may be repeated at intervals of a day or so, till physical signs and X-ray examinations demonstrate complete collapse of the lung. In order to accomplish this a positive pressure of 5 to 10 cm. of water should be produced. Once this has been obtained the condition may be maintained by an injection about once in three weeks.

Let us now consider what are suitable and what unsuitable cases. In cases where there is active and advanced disease on both sides it would obviously be useless and indeed harmful to throw all the work upon one lung. Attempts have been made, it is true, to compress the two lungs alternately, but, at any rate for the present, we may regard advanced bilateral disease as the chief contradiction. Extensive disease in other organs, especially intestinal tuberculosis, would also be a bar to operation. Of the remaining cases we may consider as specially suitable:—

(1) Those in whom the disease is advanced on one side, whilst the opposite lung is unaffected, slightly affected, or quiescent.

(2) Those in whom the temperature remains high in spite of the usual methods of treatment, and

who show signs of autoinoculation whenever they take any exercise. I may here instance one of our own cases, whose evening temperature for at least a year had been from 99 to 100 degrees, in spite of his having spent a long time at a sanatorium, and of the fact that at home he had been living in a shelter. His temperature came down to normal within forty-eight hours, and has remained at that level ever since. Numerous similar instances have been recorded. (a)

(3) Cases which are going downhill in spite of the usual methods of treatment.

(4) Early unilateral cases for whom sanatorium treatment is not available. Especially does this apply to the bread-winner of the family.

(5) Cases of severe recurrent hamoptysis.

One is often in doubt as to which side is giving rise to the bleeding, but in these cases it would be quite justifiable to compress the worse lung, and, if this had no effect, then to aspirate the gas and repeat the operation on the other side.

(6) Although most of the recorded cases have been patients suffering from chronic tuberculosis, yet this has not been by any means invariably so, and some cases of acute phthisis have been successfully dealt with.

Laryngeal tuberculosis does not appear to be a bar to the operation. In fact, several recoveries from this form of disease have been recorded. This is easy to understand, as the cessation of cough, and of the constant passage of tuberculous sputum over the larynx must be beneficial.

The question naturally arises, "What is the duration of the treatment?" No very definite answer can yet be given. There is little doubt that in advanced cases it must be prolonged for eighteen months to two years; but in very early cases cure has been reported when the gas has been allowed to absorb completely after a few months only. If the treatment has not been sufficiently prolonged recrudescence has been the rule. Under these circumstances it has been found impossible to reproduce the pneumothorax owing to the formation of dense adhesions between the two pleural layers. Therefore when it has been decided to allow the lung to re-expand a careful watch should be kept on the patient. A rise of temperature or any increase in the amount of expectoration would suggest the advisability of keeping the lung at rest for a few months longer. It is wonderful how readily the healthy portions of the lung will expand and fill the thoracic cavity, even after the treatment has lasted from two or three years. As the pleural layers come into contact there may be considerable pain and a friction rub become audible.

In discussing the results of treatment we must bear in mind that all, or almost all, the reported cases have been of one type—viz., patients suffering from very advanced disease, in whom other methods had proved incapable of arresting the morbid process, and in whom the mortality would most likely have been at least 90 per cent. Many cases have been too recently published for us to be able to judge what their ultimate fate may be, but undoubtedly the initial results have been full of promise. The way in which temperature falls and cough ceases is marvellous. Certainly well over one hundred cases have, however, been recorded in whom the treatment was commenced many years ago, and in these there would seem to have been a permanent arrest of the disease in at least 60 per cent. In many of the more recent cases immense improvement has already ensued, and patients who a few months back seemed almost moribund now

(a) This patient has now, six months later, resumed light work.

appear to be on the high road to recovery. Where deaths have been recorded during the course of the treatment they have been due, as a rule, to disease in the other lung, to tuberculous disease in some other part of the body, or to some intercurrent malady. In the few cases in which *post-mortem* examinations have been made, healing by fibrosis has generally been recorded, though this has not always been evident.

One theoretical objection has been raised to the treatment—viz., that when a *spontaneous* pneumothorax occurs in a late case of phthisis a fatal result is frequent. I hope that I have shown this to be quite a specious argument in that the two conditions are in no way comparable. In a spontaneous case there is no regulation of the pressure, and no stopping when symptoms of shock arise. Moreover, the pleural cavity is in direct communication with the lung, and is very liable to become infected from this diseased organ.

I believe that this method of treatment has a future before it, even though it be for only a limited number from out the vast array of the tuberculous. There is plenty of room for experiment and observation, and I trust that many will give this treatment a trial upon certain selected cases. Risk there may be, but who counts risk when life and death are in the balance?

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

PERFORATED GASTRIC ULCER.—MR. WILLMOTT EVANS operated on a woman, *æt.* 27, suffering from perforated gastric ulcer. The patient had had indigestion for many years, which was worse at times. The chief symptom was internal pain after meals, which was relieved by vomiting and also by lying on her face. She had had her first attack at eight o'clock, and she was at work at half-past eleven; she immediately felt an acute and severe pain in the left side of the abdomen. She felt unable to move, and as she did not improve after the administration of some brandy and water, the pain rather growing worse, she was brought to the hospital in a cab. On examination the patient was seen to be collapsed, her legs were slightly drawn up, the pulse was feeble and frequent, and the abdominal muscles were very tense. On percussion of the abdomen there was dulness in the left flank, and on the left side the muscles were evidently more tense than on the right. A diagnosis was made of perforated gastric ulcer, and it was resolved to operate immediately.

The operation was performed two hours after the onset of pain. The abdomen, having been painted with tincture of iodine, was opened in the middle line above the umbilicus by an incision about four inches long. Some free fluid immediately escaped after the peritoneum had been incised, and it had a strong odour of brandy. The stomach was gently drawn up into the wound, and it was then seen that on the anterior surface near the lesser curvature, and about midway between the cardia and the pylorus, there was a small opening which would about admit a crow-quill. From it was coming a little whitish fluid. The margins of this opening were found to be thickened. By means of Lembert's stitches the opening was closed, and the mucous membrane of the stomach brought together for about a quarter of an inch on each side. Some of the free fluid was then mopped up with sponges on holders. A further opening was next made immediately above the pubes, and through it some fluid was removed from the pelvis. A drainage tube was placed in this opening, and the original incision closed except for a second drainage tube at its upper part. Gauze dressings were applied, and the patient sent back to bed.

Mr. Evans remarked that the diagnosis of this case was fairly easy, for there was a long history of severe

dyspepsia, the pain of which was relieved by vomiting and by the prone position. These all pointed definitely to a gastric ulcer, even though the patient had never had an hæmatemesis. The sudden onset of the symptoms and the severity of the pain, the collapse, the small, frequent pulse, and the rigidity of the abdomen all pointed strongly to a perforated gastric ulcer. In this case, he said, there was no loss of liver dulness. He considered it was not at all rare to find the liver dulness, even though there may be some free gas in the peritoneal cavity. It was sometimes difficult to find the orifice of the perforation, especially when it was on the posterior surface and near the cardiac opening. In this case, however, it was quite easy, and it was also easy to close the perforation by means of Lembert's sutures. In this case there was not much extravasation, because more than three hours had elapsed since the last meal, and therefore extensive drainage was not necessary. The extravasated fluid consisted of little more than brandy and water. Sometimes, Mr. Evans said, it was necessary to make more provision for drainage. The prognosis, he remarked, was good, because there had been such a short interval (only two hours) between the perforation and the operation. Time, he thought, was the most important factor in the prognosis. Gravity carries the fluid into the pelvis, therefore it was generally advisable, he considered, to drain the pelvis, but neither drainage tube should be left in more than twenty-four hours, the peritoneum being quite capable of dealing with what is left behind.

When the case was dressed next day the patient was perfectly comfortable; much of the rigidity of the abdomen had gone and she had not vomited. The pulse was only 96 and of good volume. The drainage tubes were left out and a stitch put in place of each. She took liquid food well, and in a fortnight was allowed to get up, and then she was permitted to take some soft solid food. Three weeks after operation she went to a convalescent home, whence she returned in a month perfectly well. Before leaving the hospital her teeth were seen to, several carious stumps being removed.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

MEETING HELD FRIDAY, NOVEMBER 8TH, 1912.

The President, SIR WILLIAM OSLER, BART., in the Chair.

EXHIBITION OF CLINICAL CASES.

DR. M. A. CASSIDY showed a case of rheumatoid arthritis treated by Hoefftcke's splint. The patient, a dressmaker, *æt.* 26 was admitted to St. Thomas's Hospital in May, 1909, three years after the onset of rheumatoid arthritis. She had been bedridden and unable to stand for more than a year; both legs were acutely flexed on the thighs; the left knee-joint was fixed, and the right allowed only a few degrees of movement. The left shoulder-joint was firmly ankylosed, and the hands presented the appearances characteristic of advanced rheumatoid arthritis. Radiant heat, massage, passive movements and extensions produced very little improvement, though persevered with for four months. On September 21st, 1909, both knees were moved under an anæsthetic and put up in plaster. On September 30th the splint was fitted. On December 3rd she was able to walk with the help of sticks, and on January 1st, 1910, she could walk without assistance. When shown she could run, and her walking gait would not attract attention.

MR. WILFRED TROTTER showed a case of advanced carcinoma of epiglottis, with involvement of glands, treated by operation without laryngectomy; operation in November, 1910; no recurrence. A man, *æt.* 49. He was admitted to University College Hospital on November 3rd, 1910. Difficulty in breathing and

swallowing had been present for nine months. There was well-marked stridor. The epiglottis was greatly enlarged by an obviously malignant growth. The upper opening of the larynx was completely obscured by the tumour, which also caused considerable obstruction of the pharynx. The growth was more extensive on the right side than on the left. In the right anterior triangle a glandular mass $1\frac{1}{2}$ to 2 in. in diameter was present. It was very hard and fairly well defined, but was obviously fixed to the carotid sheath.

An operation on the glands was done on November 5th, 1910. Right side of neck dissected. Internal jugular vein and sterno-mastoid muscle removed with contents of triangles. One gland was adherent to the vein. During the operation laryngeal obstruction supervened and a tracheotomy was done.

The primary growth was operated upon on November 21st, 1910: exposure of tumour by longitudinal "trans-thyroid" pharyngotomy. Local excision, including epiglottis, part of the tongue and the anterior and lateral walls of larynx as far down as the vocal cords. The tongue and remains of the larynx were drawn together by strong mattress sutures, the gap left by removal of the tumour being completely closed. The longitudinal wound in the pharynx was then closed. Healing was fairly rapid, and there was very little leakage from the pharynx.

In March, 1912, a few glands were removed from the left side of the neck. No evidence of disease was found in them. The patient had thus been free of recurrence for two years. The case was shown as an instance of the curability of advanced carcinoma of the upper opening of the larynx and to show that cure can be effected without laryngectomy.

Dr. W. ESSEX WYNTER showed a case of acholuric jaundice. The patient was a female, *æt.* 22. Her mother had had no other children. The girl had been jaundiced from birth, the intensity varying, but being always more decided at the menstrual periods. During exacerbations the linen became stained and the urine very dark brown. Sometimes there was itching of the skin, and she often complained of dragging pain in the left hypochondrium, but had no vomiting. The motions were fully coloured and the urine contained urobilinogen but no bilirubin. The spleen was much enlarged and hard. Wassermann's reaction was negative. Bilirubin was present in blood serum. Blood count: Red cells, 2,710,000; white cells, 13,000; hæmoglobin, 52 per cent.; hæmoglobin index, 0.86; nucleated red cells, 78 per cubic millimetre.

Differential white cell count: Lymphocytes, 35.4 per cent.; hyaline and transitional, 3.6 per cent.; polymorphonuclears, 59.2 per cent.; eosinophiles, 1.8 per cent.; mast cells, 0. The fragility of red cells was represented by laking in saline solution, 0.55 per cent. as against 0.45 per cent. control.

Mr. LAWRIE MCGAVIN showed a case of resection of cæcum, appendix, ileo-cæcal valve, and 10 inches of ileum from chronic appendicitis. The patient was a woman, *æt.* 52. Four years ago she was admitted for pain in the region of the appendix, with occasional vomiting of five weeks' duration. There was no definite history of recurrent attacks. She looked sallow and ill; temperature 99.5° F. In the right iliac fossa a firm, prominent mass was felt, lobulated on the surface and dull to percussion. The mass was increasing in size, and there was a leucocytosis of 10,000. On opening the abdomen, the lower portion of the ileum, with the cæcum and appendix, were found to be involved in a dense mass of fibro-plastic material surrounded by many adhesions. The whole mass was isolated and resected, and a lateral anastomosis performed by direct suture. She subsequently developed a fecal fistula, but this ultimately closed, and since she had been in good health.

Also a case of resection of cæcum, ileo-cæcal valve, appendix, and 10 inches of ileum for obstruction following an entero-anastomosis; subsequent ventral hernia cured by filigree implantation. The patient was a woman, *æt.* 49. She was admitted in 1908 for the cure of an umbilical hernia. Eighteen months previously she had been treated for a femoral hernia which was

recurrent and strangulated, an enterectomy being performed.

While waiting for operation she developed signs of obstruction. At the operation a mass of bowel was found adherent to the middle line above the pubes, the bladder and the iliac fossa. On separation, it was found to consist of the cæcum, appendix, and nine or ten inches of ileum and some omentum. At the point of attachment of the ileum to the abdominal wall there was a perforation communicating with a fecal abscess, the lumen of the gut being here reduced to the diameter of a lead pencil, the stenosis having occurred at the site of the old anastomosis. The whole mass was excised and a lateral anastomosis was performed. The abscess cavity being drained, a ventral hernia subsequently appeared and became rapidly larger. Eight months later this was cured by the implantation of a 6-in. filigree, since when the patient had been in good health.

Also a case of resection of cæcum, ileo-cæcal valve, appendix, and 5 inches of ileum for sarcoma; anastomosis by Murphy's button; button retained for four years. The patient was a man, *æt.* 24. In 1908 he was taken suddenly ill with pain in the region of the appendix, set up by lifting a heavy girder. This lasted three weeks, when he commenced to vomit, and was admitted to the Seamen's Hospital. His bowels acted normally and he had no pyrexia. He stated that he had had a similar attack six months previously.

On admission he looked very ill, but his pulse, like his temperature, was normal. In the right iliac fossa was a mass large enough to produce an obvious bulging of the abdominal wall; it was firm, fixed, lobulated and devoid of tenderness. There was neither hyper-æsthesia nor rigidity, and the respiratory movements were good. Nothing was felt per rectum, there were no other lumps in the abdomen, and the hepatic dulness was normal.

Under spinal analgesia the abdomen was opened, and the mass was found to involve the organs above mentioned; no glands were felt in the mesentery or portal fissure; the whole mass was therefore resected with the corresponding iliac fascia and mesentery, and a lateral anastomosis performed. Under the threatening condition of the patient, this was rapidly accomplished by means of a Murphy's button. He recovered well, but had not passed the button, which had remained for over four years in the blind end of the ascending colon without causing the patient the least inconvenience. For this reason he refused to have it removed.

Microscopically the mass was a myxo-sarcoma apparently arising in the cæcum at or about the base of the appendix. There was much inflammatory infiltration about the latter, which was, however, irrespective of the tumour.

Also a case of gastro-enterostomy for hæmatemesis, followed by ileus and fecal vomiting; cæcostomy; subsequent ventral hernia; cure by implantation of 6-inch filigree. The patient was a man, *æt.* 44. In 1909 he suffered from gastric ulcer, and was admitted to the Seamen's Hospital with severe hæmatemesis, for which gastro-enterostomy was performed. The hæmorrhage ceased, but 48 hours later vomiting, becoming rapidly fecal, set in. The abdomen was reopened, and nothing was found except a general condition of paralytic ileus. The cæcum was therefore opened and the ileum intubated. The vomiting ceased and the patient made a good recovery. Later the cæcum was replaced, but a ventral hernia soon developed at this point, and four months later a 6-inch filigree was implanted under spinal analgesia. He had never had the least discomfort from his gastro-enterostomy, his cæcostomy, or his implantation.

Dr. F. E. BATTEN showed two cases illustrating the value of celluloid splints in the treatment of acute poliomyelitis. He said that the importance of the use of splints in the treatment of the early stages of acute poliomyelitis in order to prevent deformity and hasten recovery was fully recognised, the paralysed muscles being placed in a position of relaxation. It was difficult to obtain one splint suitable for all pur-

poses. It was important to have a splint which is comfortable for the child, out of which it cannot wriggle, which is easily removed, which keeps the leg in a good position, and which can be worn day and night, whether the child is up or in bed. The celluloid splint answered all these requirements, and was especially suitable for this purpose—it was easily made, extremely light, it fitted the leg accurately, and it could be applied within the first few weeks of the onset of the disease, and was not expensive. It could be worn not only during the earlier, but also during the later stages of the disease.

There were three processes involved in making these splints: (1) the taking of the cast of the patient's limb, (2) the making of the positive from the cast, and (3) the moulding of the splint on to the positive. It was the first, the taking of the cast of the leg, which was most important, for it was essential to keep the limb in a good position whilst the cast was being made.

These splints were first made by Calot, of Berck-sur-mer, and introduced into this country by Gauvain, who had used them extensively in the treatment of tuberculous disease of bones and joints.

Mr. E. C. HUGHES showed two cases of congenital syphilitic disease of the knee-joint.

CASE 1.—A boy, *æt.* 12. In 1908 the left knee was noticed to be swollen. In 1909 fluid was aspirated from the joint for bacteriological examination; no organisms were found. In 1912 the knee was much swollen, and there was considerable hypertrophy of the synovial fringes. Fluid from the joint was injected into a guinea-pig, with no result. Wassermann reaction positive. In spite of the marked swelling of the joint its functions were not much interfered with.

CASE 2.—A girl, *æt.* 13. Two years ago the right knee was noticed to be swollen. The knee was in a very similar condition to that of the preceding case.

Mr. DONALD ARMOUR showed a case of chronic circumscribed inflammation of the corpora cavernosa. The patient, aged 56, noticed a "growth" on his penis twelve months ago, this had gradually grown larger, spreading upwards towards the root of the penis. It was painless. On erection the penis became dorsiflexed at the site of the inflammatory plaque. He had gonorrhoea when a boy, but denied syphilis. Urine was normal.

Dr. JAMES GALLOWAY showed a case of tuberculous peritonitis. The patient, a boy, *æt.* 10, was sent to hospital with the diagnosis of splenomegaly. The abdominal tumour had been noticed from the beginning of August, but the patient had been ailing for some months before that date. An indurated area could be readily felt occupying the upper portion of the anterior and lateral aspects of the abdomen. Its lowest position was in the central line, where its edge could be defined two finger-breadths below the umbilicus. The indurated mass was very superficial, giving the impression of being incorporated with the abdominal wall, especially in the umbilical area. The skin at the umbilicus and the immediate neighbourhood appeared to be directly adherent to the underlying indurated mass. There was evidence of a small amount of fluid in the abdominal cavity. The glands in the groin were enlarged. A tuberculin cutaneous reaction gave a very doubtful result. There was a slight degree of fever, his temperature varying between 97.4° F. and 100° F. There was no evidence of pulmonary tuberculosis.

One of the glands was removed from the groin on October 1st, and showed characteristic tuberculous structure. The case was brought forward on account of the early and probably extensive tuberculous infiltration of the omentum with adhesions to the anterior abdominal wall and the special involvement of the superficial structures in the neighbourhood of the umbilicus.

Also a case of sclerema cutis (adultorum). The patient had attended the meeting of the Section on May 31, 1912. The thickening and induration of the skin at that time affected the face, neck, shoulders and trunk to about the level of the loins, and with scattered areas on the extremity. Movements of the arms, neck and face were very difficult. There was a great

improvement in his condition, large areas of the skin having returned to its normal state.

The treatment consisted of vigorous massage during May, June and July, and the early part of August. He had had no special treatment since that time, but had recommenced treatment by massage. The hardening and thickening of the skin was noticeable only on the face and neck, and very slightly on the trunk. The areas still affected were not nearly so firm as when previously affected.

Dr. R. HUTCHISON showed a case of Hirschsprung's disease. The patient, a man, *æt.* 39, had suffered all his life from constipation with intermittent distension of the abdomen. During the past three or four months the constipation had been intensified, and there had been much flatulent distension without either pain or vomiting. His general condition had remained fairly good.

SECTION OF OPHTHALMOLOGY.

THE FIRST CLINICAL MEETING OF THE SECTION WAS HELD ON WEDNESDAY, NOVEMBER 6TH, 1912, under the Presidency of SIR ANDERSON CRITCHETT, C.V.O.

Mr. HERBERT FISHER showed a case of subhyaloid hæmorrhage, with drawing. He urged the abandonment of the term "subhyaloid hæmorrhage," as the hæmorrhage was intra-retinal; he suggested the words "semi-lunar retinal hæmorrhages." The President agreed with the suggestion.

Mr. A. W. ORMOND showed a case of pemphigus of the conjunctiva, followed by essential shrinking. The patient was *æt.* 24, and his condition as well as his sight were now so bad that he pleaded for something to be done. Mr. Ormond proposed to clear away the conjunctiva as much as possible, and substitute mucous membrane from elsewhere.

Mr. FISHER referred to a case of pemphigus of the conjunctiva, which was later under Mr. Lawford's care, in which a vaccine made from the contents of the patient's own vesicles was administered for some time, but without marked benefit.

Mr. LAWFORD confirmed the fact that there was no definite improvement after the vaccine treatment.

Mr. BISHOP HARMAN described a very severe and extensive case, involving larynx, pharynx, mouth, and both eyes, in which no treatment benefited.

Mr. R. GREEVES showed a case of paralysis of the third nerve with periodic spasm of irido-ciliary muscles. He said he could not make out any relationship between the movements of the two eyes. He thought the right pupil was a little unsteady, but it seemed to have nothing to do with the contractions and dilatations of the other eye. Mr. Herbert described a somewhat similar case, and suggested an explanation, namely, that a portion of the nucleus of the third nerve was non-existent and the other portion of it was weak, so that it was able to overcome the innervation of the higher centres only after an interval of rest.

Mr. HERBERT PARSONS showed a case of Moorten's ulcer, with ulceration of the sclerotic, and Mr. Leslie Paton demonstrated a modification of Herbert's operation for chronic glaucoma, in which his object had been, while retaining the simplicity of Herbert's operation, to procure a more permanent result. Mr. Herbert described his own attempts in the same direction, emphasising the importance of not reducing the nutrition of the flap too much. The difficulty arose chiefly in subjects who had very shallow anterior chambers.

Mr. E. NETTLESHIP read notes of a case in which a sarcoma of the choroid was seen as a small spot of disease, but its true nature not recognised, about 20 years before the diagnosis of tumour was made, and 25 years before removal of the eye. The case showed the importance of watching over long periods, when possible, the behaviour of certain solitary spots on patches of dusky discoloration that were occasionally seen in the choroid during ophthalmoscopic examination, some of them probably being the beginnings of malignant growth, although others were, no doubt,

congenital and stationary. Such solitary, non-inflammatory patches might sometimes be the counterparts of the minute sarcomatous growths, of which nine or ten examples had been accidentally discovered after death and published during the last few years.

MR. NETTLESHIP also read a joint communication by himself and MR. A. HUGH THOMPSON on an extensive pedigree of Leber's disease of the optic nerves, which illustrated the occurrence of the malady in females, recovery in some cases in both sexes, descent to all the children of one of the affected women, diabetes with blindness of unknown nature in one member, high infantile mortality in the very large family of one affected man, and absence of influence of the optic nerve disease upon prospect of life.

The PRESIDENT paid a tribute to the labours of Mr. Nettleship in the domain of hereditary disease, and referred to the changes of medical opinion on the subject of heredity. Mr. Hugh Thompson supplemented the paper in respect to one patient, who was a heavy smoker, and suggested that in cases of tardy recovery from tobacco amblyopia enquiry should be made as to any connection with Leber's disease.

MR. A. W. ORMOND read a paper on a case of
RETINO-CHOROIDITIS JUXTA-PAPILLARIS.

The patient was a man *æt.* 20 who found, on awaking, that he could not see very well with his right eye. He had had a little pain in the eye a week previously. On examination there was found keratitis punctata, and a patch of acute choroiditis touching the upper margin of the optic disc, and spreading upwards. Œdema of the retina spread over and beyond the patch. Vessels which passed over the inflamed area were partly obscured, and the arteries diminished in size; there was also some haze in the vitreous. Von Pirquet's reaction was positive. The inflammation gradually subsided, and the patient now had full visual acuity, but a large sector of his field of vision, stretching from the blind spot to the extreme periphery, was entirely absent, and he had no perception of light in the area affected. The defective area in the field of vision was clearly due to the obliteration of a branch of the central retinal artery by the pressure of the inflammatory swelling. Under the title *retino-choroiditis juxta-papillaris*, Professor Jensen, of Copenhagen, published four similar cases in *Graefe's Archives* in 1909.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

The President, R. D. PUREFOX, P.R.C.S., in the Chair.

MEETING HELD FRIDAY, OCTOBER 25TH, 1912.

THE PRESIDENT thanked the Section and the Council for electing him President. He then briefly reviewed the work of the last Session. He said that physicians and surgeons of the Dublin School had entered into a splendid heritage of traditions and reputations—an inheritance which was not built up without hard work, devotion to their hospitals, and to the students who studied in them. He thought it would be admitted that such a heritage would suffer, and could not be handed down to their successors if they did not pursue the same means.

CASE OF CEREBELLAR TUMOUR TREATED BY DECOMPRESSION.

MR. A. A. MCCONNELL showed a case of cerebellar tumour for which Cushing's sub-tentorial decompression operation had been performed. Before operation the patient had headache, vomiting, partial optic atrophy, vertigo, and ataxia. She was also subject to seizures, in which all the muscles were thrown into a state of tonic contraction. The localising symptoms were:—Tinnitus in left ear; diadochokinesia, which was well pronounced on the left side; and constant deviation to the left side in walking. Optic atrophy was also more marked on the left side. Wassermann's reaction was negative. At the operation a tumour was palpated in the left cerebellar hemisphere. There had been no recurrence of headache, vomiting,

vertigo, or tonic muscular spasms since operation. Removal of the tumour was to be attempted at a second operation. Hedonal was the anæsthetic used.

The PRESIDENT asked if the flow of cerebro-spinal fluid had ceased.

MR. E. H. TAYLOR said that there were two stand-points in these cases:—(1) the diagnostic; (2) the operative. The diagnosis in the present case was very fully gone into. With regard to the operative treatment his experience had not been so satisfactory as Mr. McConnell's. Access was not so easy when the patient was lying on the side as when in the face down position. He agreed that it was well to expose both hemispheres of the cerebellum, and he thought the bilateral exposure was to be preferred.

DR. DENHAM suggested that there was still a great deal of bulging, and he would like to know whether there was at present a greatly increased intracranial tension, and whether this was attributed entirely to the tumour or to the increase of the cerebro-spinal fluid. He also asked if urotropine was indicated in these cases.

MR. PEARSON said it was to be regretted that cases of the kind were not got in earlier stages by the surgeon. When optic atrophy sets in the patient's sight could not be restored. He considered that even if the growth was believed to be a gumma it was no reason why the case should not be submitted to surgical treatment. The patient's speech at present seemed somewhat slurring and slow, which he thought should be regarded as a symptom that there was some pressure on the bulb.

MR. MCCONNELL, replying to the remarks, said with regard to the President's inquiry the cerebro-spinal fluid discharged very copiously from the eighth to the tenth day and then the sinus closed. During operation the patient was kept in the prone position, and there was free access to the seat of operation. Although before operation the patient had optic neuritis far advanced on the left side and considerably on the right, yet her sight improved immediately after operation, but it had since deteriorated.

HEDONAL AS AN ANÆSTHETIC.

MR. H. DE L. CRAWFORD read a paper on this subject, for which see page 515.

MR. W. I. DE C. WHEELER thought the question of anæsthesia was not in a satisfactory state at present. As to hedonal, he considered that its administration could not be praised or condemned until there was more experience of it. In his opinion there was sometimes a difficulty in giving the anæsthetic, as patients very often objected more to the giving of an intravenous injection than to the operation. He mentioned that he had been using omnopon in simple operations, and so far had found it satisfactory. When given before the administration of ether, patients when anæsthetised would remain so for hours. There was a complete absence in every case of anything in the nature of cyanosis.

DR. KIRKPATRICK had not seen hedonal used, but it seemed to him, from the theoretical point of view, that it was attended with great advantages and some considerable disadvantages. It was admitted that present methods of anæsthetising patients were not altogether satisfactory. Whether it was the fault of the methods or the patients, it was exceedingly hard to get satisfactory relaxation of the muscles, especially in pelvic operations, and the surgeon might be very considerably hampered in his work on this account; consequently, any method that would improve this state of things would be of very great value. He had seen so many methods of using different drugs as anæsthetics introduced that it made him doubtful, as over and over again, notwithstanding new methods being put forward as panaceas, return had to be made to ether. He therefore thought that no one had yet sufficient experience to be able to pronounce definitely on hedonal. Regarding the point that the anæsthetist could administer hedonal so that he could be out of the way of the operator, it should not be lost sight of that, no matter how the anæsthetic was given, the anæsthetist must have access to the patient's head.

DR. WALTER SMITH said that so far all forms of anæsthetics administered by inhalation, excluding

morphia, belonged to the marsh gas series. Local anæsthetics belonged to the aromatic group. He demonstrated by formulæ how the various forms were built up, taking marsh gas as a base.

Mr. CRAWFORD, in replying to the remarks, said his experience was that patients would rather have the small operation necessary to administer hedonal than to have the mask placed over their face. He considered that it was much more under control than omnopon. With regard to the danger of cyanosis, if the anæsthetist was at the patient's feet instead of at the head, he found it necessary to stay at the patient's head, and to signal when the tap was to be turned off. He considered the anæsthetic as safe as any other in practice.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

SPECIAL CLINICAL MEETING, HELD ON FRIDAY,
NOVEMBER 1ST, 1912.

The President, Dr. G. P. SHUTER, in the Chair.

THE following cases were examined and discussed:—

Mr. ASLETT BALDWIN: (1) Tuberculous Disease of the knee-joint in a girl, æt. 12. The right knee-joint was distended with fluid, there was some thickening of the synovial membrane, but a remarkable absence of pain, tenderness and rigidity. The disease dated back about 8 months. There were no signs of congenital syphilis, a Wassermann reaction was negative, but a positive von Pirquet reaction was obtained. (2) A man, æt. 54, from whom an epithelioma of the inner side of the right cheek was excised six months ago, together with the glands on the same side of the neck. There were no signs of recurrence, but a patch of leucoplakia developed recently on the inside of the opposite cheek and was removed as a precautionary measure. (3) Rodent ulcer on dorsum of hand in a woman, æt. 68. It was proposed to treat it with zinc ionisation, and subsequently with radium if necessary.

Mr. E. P. ISAACS COKE showed an interesting case of Polycythæmia in which the erythrocytes varied between 6 and 12 millions. The complexion of the man during ten years under observation had always been of a deep red hue, the mucous membranes almost purple, and the conjunctivæ injected. Before a severe hæmorrhage, following the extraction of some teeth, the spleen was two inches below the costal margin, and was only just palpable a month later. The patient suffered from headache, giddiness and general weakness. Rest seemed to be the only treatment from which he derived benefit.

Mr. T. C. STOKEY (for Dr. H. J. Davis): (1) Labyrinthine Vertigo in a woman, æt. 33. The attacks began three years ago and were getting much more severe, but she never lost consciousness or vomited. Examination showed the right ear to be normal, but on the left side there was absolute deafness. Tests suggested that the left labyrinth was not entirely destroyed. (2) Hernia Cerebelli in a boy, æt. 8, following the evacuation of a cerebellar abscess six months ago. The hernia was kept banded under pressure and had completely disappeared.

Dr. GRAINGER STEWART remarked that in his experience this was the most successful method in dealing with cerebral herniæ.

Mr. H. TYRRELL GRAY: (1) A boy from whom a Naso-pharyngeal tumour was removed ten months ago. The tumour, which proved to be a myxo-fibroma, grew from the base of the skull and left inner antral wall, the septum being pushed over to the right side. (2) Case for diagnosis. Achondroplasia possibly, but Mr. ADDISON suggested it might be some inflammatory condition. An X ray of the hand was shown.

Dr. F. S. PALMER: (1) and (2) Friedreich's Ataxia in a brother and sister, both presenting the characteristic features of the disease. The sister was 18 years of age and the brother two years younger, and in each case the disease seemed to have some relation to an attack of influenza acquired about three years ago.

The only other child in the family, a brother, æt. 19, was healthy, both parents were alive and well, and no history of nervous disease could be traced in previous generations, nor among the collateral branches. (3) Rheumatoid Arthritis. On a previous occasion when this patient was shown at one of the society's meetings there had been some discussion as to the nature of a swelling in the region of the left shoulder-joint. The swelling had since been explored and found to be a large thick-walled bursa under the deltoid.

Mr. J. PARDOE: Large Cyst of the Pancreas drained, at the first operation, through an epigastric incision, the stomach and transverse colon being densely adherent to the cyst wall. After slow refilling of the cyst a second operation was performed, and the cyst was drained by an extra-peritoneal incision through the loin. The cyst was now filling again, but much more slowly.

Mr. TYRRELL GRAY, Dr. SHUTER, and Dr. OGIER WARD made suggestions in the event of another operation being necessary.

Dr. H. PRITCHARD: Aneurysm of first part of the Aorta coming through sternum in the region of the third right costal cartilage. The man was 43 years of age, had been in the army and served through the South African War. Dr. Pritchard drew attention to the signs of pressure on the superior vena cava, not a common phenomenon, but well seen in this instance. The patient gave a positive Wassermann reaction, and had much improved under treatment with iodides and rest.

Dr. A. E. SAUNDERS and Dr. A. C. D. FIRTH presented a series of eight Cretins and two children affected with Goitre. Dr. Saunders usually gave 3 grains of thyroid extract three times a day, during the growing period, in well-marked cases. In one of his patients, however, a girl, æt. 4, $\frac{1}{2}$ grain doses three times daily produced tachycardia. The boy, æt. 9 $\frac{1}{2}$, had grown 4 $\frac{1}{2}$ inches since commencing treatment 8 months ago. The young woman of 17 he had brought before the society 13 years ago. The brother and sister affected with goitre, æt. 12 and 11, were the children of a father who suffered from a large goitre from the age of 14 to the age of 20 when it disappeared, and they did not show signs of cretinism. These cases were allied to the cases of goitre with cretinism which occurred in the Swiss Valleys and Peak District, whilst in cases of sporadic cretinism the occurrence of goitre was certainly the exception. Dr. Firth, when showing his four cretins, desired to draw attention to the fact that frequently at the commencement of thyroid treatment the patient became bald, and afterwards grew a stronger and thicker crop of hair. Also that occasionally an overdose of thyroid might result in the production of glycosuria. The girl, æt. 14, mentally rather backward, developed slight glycosuria on taking 7 grains daily. She had been under treatment since the age of 6 months, and now took 5 grains daily. During the last 12 months the right lobe and isthmus of the thyroid had shown signs of swelling. The girl, æt. 2 $\frac{1}{2}$, commenced treatment at the age of 8 months and was taking 3 grains daily, with excellent results.

Dr. T. GRAINGER STEWART: Pituitary Tumour in a man, æt. 52. Progressive failure of vision during the last 17 years, commencing in the temporal fields, had reduced the patient to such a condition that he only retained a reduced nasal field in the left eye. He became pale, waxy-looking and adipose. Loss of hair was a marked feature, and he showed regression towards the female type. Testicular atrophy developed years ago, and along with these changes an increase in the size of the hands and the malar region of the face. There was an increased sugar tolerance, and an X-ray examination revealed enlargement of the sella turcica. Some signs of acromegaly were present, but in the main the symptoms pointed to a loss of function of the posterior lobe, or hypopituitarism.

Mr. BISHOP HARMAN referred to two cases he brought before the society last year. They had been under treatment for two years and had remained quite stationary. In one case thyroid extract, 15 grains per diem, was administered for a month, then a rest for a fortnight; the patient said she appreciated an improve-

ment in her condition each time she resumed the extract. In the other case a man who lived in the country attended the local slaughter-house and extracted the pituitary body of sheep and oxen for immediate consumption. In neither case had any acromegalic symptoms appeared.

Dr. J. BERNSTEIN exhibited two cases of Glossitis due to syphilis, and wished to point out the frequency of a negative Wassermann reaction associated with chronic tertiary lesions in acquired or congenital cases: (1) A woman, *æt.* 35, suffering from Congenital Syphilis. The tongue showed chronic thickening with fissures, and obstinate dyspepsia was a secondary result of the painful condition of that organ. In spite of the presence of Hutchinson's teeth and a family history of syphilis the Wassermann reaction was negative, but the latter will not prevent immediate treatment with 606. (2) Woman, *æt.* 75, chronic superficial glossitis of a different type, the tongue being glazed. Wassermann reaction positive.

THE LIVERPOOL MEDICAL INSTITUTION.

FIRST PATHOLOGICAL MEETING OF THE SESSION, HELD ON THURSDAY, OCTOBER 31ST, 1912.

Mr. F. T. PAUL, Past President, in the chair.

The evening was devoted to the consideration of MALIGNANT DISEASES.

The following specimens were shown:—

Mr. COURTENAY YORKE: Carcinoma of the œsophagus which had involved both recurrent laryngeal nerves. During life there was complete paralysis of the larynx.

Dr. R. E. HARCOURT and Mr. BICKERTON: (1) Epibulbar melanotic sarcoma in a woman *æt.* 37. (2) Perithelioma of the orbit in a woman *æt.* 73.

Mr. ARTHUR EVANS: (1) Carcinoma of the cervix uteri (two cases). (2) Annular carcinoma of iliac colon. (3) Epithelioma of mouth. (4) Epithelioma in appendix scar. (5) Epithelioma of penis. (6) Malignant testis.

Dr. BUCHANAN and Dr. LISSANT COX: Carcinoma of an accessory thyroid or of the thyroglossal duct.

Mr. DOUGLAS CRAWFORD and Dr. S. W. McLELLAN: (1) Malignant disease of lower end of œsophagus. (2) Malignant disease of colon. (3) Malignant disease of breast; recurrence; X-ray treatment.

Mr. THELWALL THOMAS and Dr. REES: (1) Papilloma of prepuce, early malignancy. (2) Malignant breast, showing pigmentation due to hæmorrhage from previous operation. (3) Malignant bladder and secondary glands. (4) Endothelioma of parotic. (5) Epithelioma of scrotum.

Mr. R. E. KELLY: (1) Carcinoma of small gut. (2) Lympho-sarcoma of neck.

Mr. G. P. NEWBOLT: Carcinoma of the hepatic flexure of the colon.

Dr. NATHAN RAW: (1) Osteo-sarcoma of lung (secondary). (2) Lympho-sarcoma of lung. (3) Lung showing cancer and tuberculosis. (4) Sarcoma of the heart.

Mr. F. T. PAUL gave a very instructive photomicrographic demonstration with lantern slides of epitheliomata of varying degrees of malignancy. He pointed out how an accurate prognosis could be given from the appearances of the sections. His opinions had been confirmed by the subsequent histories of the cases.

Dr. BLAIR BELL showed a fox-terrier bitch *æt.* 16½ years. Two years ago a lump appeared in the right inguinal mamma following long continued mastitis. This lump was excised under B-Eucaine anaesthesia. Six months later a recurrence occurred locally. Both inguinal mammae with all the inguinal fat and glands (which were affected) were then removed under ether anaesthesia. Perfect recovery was made, but now there is a recurrence in a gland lying superficial to the ribs on the right side.

Dr. HUBERT ARMSTRONG read a note on a case of *endothelioma of the heart*, and demonstrated the sections and drawings made for him by Professor Mönckeberg. The tumour was a lymphangio-endo-

thelioma of the A.—mode, causing heart block with Stokes-Adams syndrome in a boy *æt.* 5 years. The case has been reported in full elsewhere. (a)

Dr. WAKELIN BARRATT read a paper on RECENT EXPERIMENTAL INVESTIGATIONS IN REGARD TO THE PRODUCTION OF IMMUNITY TO CARCINOMA.

Dr. Wakelin Barratt first compared the histological characteristics of mouse carcinomata with human carcinomata. He illustrated his remarks with a series of lantern slides. He also pointed out the differences in the way the two types of malignant disease progress, and produce death. He next dealt with the experimental work which has been carried out on mice to produce immunity to or to cure mouse carcinoma. He called attention to the fact that many living tissues from the mouse or the foetal mouse appear to have the power of producing immunity or of arresting the growth. He emphasised the fact that the tissues used must be living.

Mr. F. T. PAUL thought the cure of carcinoma by therapeutic methods was far distant, but hoped that experimental research would be continued with vigour.

Dr. BLAIR BELL believed that a method for treating cancer therapeutically was within sight; if not absolute cure, at least one which would supplement surgical procedures. He mentioned some of his own attempts to arrest the disease in the human subject.

Mr. RUSHTON PARKER congratulated Dr. Barratt on his lucid paper, and alluded to the excellent work Dr. Barratt has already done. He was particularly impressed by the modest and restrained manner in which the various facts had been brought forward. It was most important that no false hopes should be raised.

ULSTER MEDICAL SOCIETY.

The opening meeting for the winter session was held in the Medical Institute, Belfast, on Thursday evening, November 7th, 1912.

The retiring President, Dr. H. L. MCKISACK, introduced his successor, Dr. R. W. LESLIE, who delivered an address on

THE INFECTIOUS DISEASES INCIDENT TO SCHOOL LIFE, THEIR EARLY RECOGNITION, TREATMENT, AND CONTROL.

In accordance with custom, Dr. Leslie referred to the losses sustained by the society during the past year. Two former presidents have passed away—Dr. Henry Whitaker, who for more than fifteen years was medical officer of health for the city, and Lieutenant-Colonel Macfarland, who after twenty years' service in the army engaged in private practice in Belfast, and was well known as an ardent temperance reformer. Dr. Stuart Dickey, who had just arrived in Canada to enter on his work as professor of anatomy in Montreal; Dr. R. C. Parkes, of Newtownards, and Dr. John Simson, who was lost in the "Titanic," were also referred to in feeling terms. After some reference to the Insurance Act, Dr. Leslie said that his choice of subject had been decided by the fact that for 18 years he had acted as medical officer to one of the largest boarding schools in Ireland (the Campbell College). During those years he had medical charge of 125 residents, on an average, and among them there were frequent outbreaks of infectious ailments. It was notable that these outbreaks nearly all occurred in the winter half of the year, and chiefly in February and March. The commonest ailment by far was measles, but the most important, from various points of view, was scarlatina. The difficulties that arose in diagnosis were great, and as the result of his experience he would repeat the Scriptural warning, "Let him that thinketh he standeth take heed lest he fall." He gave particulars of the epidemics, and remarked on the difficulties of tracing their beginnings. He believed the initial stages of scarlatina were the most infectious. He agreed with Dr. Clement Dukes's warning about the necessity for careful watching in every case of sore throat. Referring to measles, Dr. Leslie said that it was remarkable that they had never had a case in the school between April 1 and September 30 in any year. Mumps came second

(a) "Deutsch. Archiv. f. Klin. Med.," March 13, 1911.

to measles in frequency, and in several cases acute pancreatitis had occurred as a complication, with alarming abdominal pain, vomiting, and collapse. Orchitis occurred in more than 10 per cent. of the cases, and in these the constitutional symptoms were generally severe.

At the conclusion of the address a vote of thanks to the outgoing President, Dr. MacKisack, for his conduct during the past year, and to the incoming President, Dr. Leslie, for his interesting address, was moved by Professor LINDSAY, seconded by Professor Sir WILLIAM WHITLA, and passed by acclamation.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Nov. 9th, 1912.

ANGINA PECTORIS.

ANGINA PECTORIS, provoked by walking or by an effort, is due, says Dr. Fiessinger, to divers causes: coronitis with obliteration of the coronary arteries or aortic insufficiency, myocarditis, hypertension of interstitial nephritis, obesity and aerophagia. The two last causes can be easily cured by dietetic régime (lacto-vegetarian).

Coronitis of specific origin yields to the mercurial treatment; aortic insufficiency is amenable to small doses of iodides, while the pain due to interstitial nephritis may be successfully treated by very small doses of digitaline, theobromine and laxatives. The same treatment holds good for mitral insufficiency.

All the former are relieved by small doses of morphia, nitrites, prolonged rest in bed and light repasts (seven daily). By these means persons of 70 years of age and upwards may be completely relieved provided the dietetic treatment be prolonged one or two years.

In patients suffering from dilatation of the stomach with great flatulence the diagnosis is very difficult, but morbid syncope due to extreme distension by the gases is very rare.

The distinction between true angina pectoris and nervous angina, described by Professor Robin in dyspeptic patients with secondary fermentation, is easy by assuring oneself of the integrity of the cardiovascular system and the presence of gastric disturbance, repetition of the attack after meals and their cure by régime, saturation of the gastric secretion after food by the administration of alkalies.

The prognosis of angina pectoris, says Dr. Fiessinger, is consequently not so sombre as one may think.

A CURIOUS CASE OF LEAD POISONING.

A curious case of lead poisoning from a gunshot-wound is reported by Dr. Lombard, of Algiers. A lad of 15 received the charge of a shotgun in the hand and forearm. The wound was disinfected with tincture of iodine, the palmar artery tied and a suitable dressing applied. The bones were untouched, but the grains of shot were so numerous and so disseminated that the surgeon had either to abandon them or amputate the forearm. However, the temperature was normal, no local inflammatory reaction, although the forearm was very swollen, the appetite was good and sleep natural.

During twelve days his general condition remained satisfactory, while the œdema rapidly disappeared. But soon anæmia set in, with insomnia, headache, vertigo, wasting. On account of these symptoms, the parents objecting to amputation, an attempt was made to extract some of the shot grains; the muscles when cut were found to be greenish and friable! An elastic band was placed above the wound to prevent massive absorption, and the wound was dressed. The patient, who had previously complained of colic and vomited some greenish matter, succumbed ten hours after the operation.

Here was a rapidly fatal case of acute lead poison-

ing three weeks after the traumatism and in a healthy individual

While a relatively large isolated bullet is frequently well tolerated, small and numerous projectiles disseminated in vascularised muscles are more dangerous as their absorption by the post-traumatic œdema is always possible. Hence the necessity of sacrificing the wounded region as soon as the condition of the blood reveals the effects (rapid decrease of the red corpuscles with granular alteration) of saturnine intoxication.

THE TRAFFIC IN HUMAN HAIR.

Traffic in human hair is growing extensively since fashion imposes the wearing of chichis on our fair sisters. China is the great exporter of hair, and the best market is New York, whither 282 tons were sent last year, representing £150,000. But Vienna, London, and especially Paris, are not much behind.

The hair from China does not come from the dead, as was often feared, but almost exclusively from hair falling during the toilette of the Celestials, collected with care by hairdressers and servants.

For many years the hair was exported in the "raw" state—that is to say, with no other treatment than the disinfection imposed by the sanitary service. But recently several manufactories have sprung up, one of which employs no less than 600 hands. Here the hair is combed and washed in a bath containing soda, black soap, and ammonia; after drying in a current of hot air, the hair is plunged for 24 hours into a vat of boiling water. It is finally sterilised in an autoclave, and then receives the colour desired, as there is very little use for black hair.

Some years ago the region of Limoges, in the centre of France, and some parts of Brittany were great markets for human tresses; the young peasant girls sacrificed, however reluctantly, their luxuriant hair against one or two hundred francs, but to-day the belles prefer keeping the ornament nature has so richly provided them, and refuse the tempting offers. On the other hand, the market has considerably fallen on account of the competition from the East.

GERMANY.

Berlin, Nov. 9th, 1912.

At the 84th meeting of the Naturforscher und Aerzte, in the Pathological Section, Hr. Heller, Kiel, spoke on

REGENERATION OF THE MUSCLES OF THE HEART.

It was a well-known fact, he said, that voluntary muscle could to a great extent regain its volume and capacity for function after it had undergone degenerative processes after acute febrile diseases. Such a regenerative power on the part of the cardiac musculature had not yet been generally recognised. The newest work on pathology did not mention it at all; this was the more striking as there were sufficient clinical observations known to compel an acknowledgement of such a regenerative power on the part of the heart muscles. Thus White had reported on 78 patients, who, after diphtheria, had left the Boston Hospital with cardiac disturbance; the majority of the cases showed a marked dulness extending to the left, they also had systolic murmurs, etc. He observed these cases further, and found that they mostly improved; in 17 per cent. of the cases, however, the symptoms remained for more than six months; but with these also the progress was mostly favourable. Dieteren found dilatation of the heart 15 times in 47 cases. This dilatation must be the result of a degenerative process. If a transient dilatation could be recovered from and explained on the ground that the affection was only slight, a restitution after months of dilatation could only be due to regeneration of the cardiac muscles. This conclusion, as far as the speaker knew, had never been brought forward. He believed he should be able to show the truth of it through his own observations. As early as the year 1889 he saw the regenerative process in the case of a boy of 10, a patient of a colleague. The boy had died from an embolism springing from the left ventricle. There were all the transition stages from

the finest spindle cells with two or three transverse striæ at every nucleus end to longer delicate striped muscle on to the normal.

He had followed these observations further, and found that such regeneration often took place extensively. There were great difficulties in prosecuting the inquiry, as the striping was not well retained, as the patient often died from some febrile affection. But, as the preparations showed, such regeneration frequently did take place. The changes that took place were many. The nuclei of the muscles often showed enlargement, increase in number and great facility of staining, so that often true multinuclear giant cells appeared; these muscle "buds," however, did not go on to further division with formation of young muscle, and he had never been able to satisfy himself that he had seen fibres given off. The four preparations shown showed all the transitions from simple incurving to almost complete separation, so that before the complete division the nucleus represented the figure of a long-drawn-out horseshoe. The nuclei showed a further change in that they lengthened often to three, or four, or five times their ordinary length. Romberg had seen such fibres of a length of 160 micra. They were often arranged lengthwise; there then appeared two or three small nuclei close together, especially at the end of the muscle fibres. These were then frequently split up into numerous small nucleated processes, concluding with a longer and wider covering of myogene fibre. These developed into delicate bands containing two or three small nuclei, in which when quite fresh striæ were to be seen distinctly. All these processes were met with in the diseased myocardium.

With all these, which might be looked on as processes of regeneration of muscle, there were in greater or lesser numbers all possible cellular elements—leucocytes, lymphocytes, plasmic cells—which often made recognition of the more delicate elements more difficult. The preparations shown illustrated the very varied character of the changes. They were taken from a number of children who died from diphtheria, also from older individuals who had died of myocarditis; in four of the cases the myocarditis was apparently on a syphilitic basis. Clinically, with such children with post-diphtheritic heart symptoms it was of the utmost importance that the heart should be protected from all strain; time must be allowed for regeneration. If time was not allowed for this the bulging of the lower part of the left ventricle would become greater; in this depression there were layers of fluid not in motion, which in the altered heart might easily lead to thrombosis. The speaker had seen several such cases. Moreover, it was of further importance that time should be allowed for the thrombus to get covered with an endocardial covering; it was thereby rendered harmless.

AUSTRIA.

Vienna, Nov. 9th, 1912.

CHRONIC CARDIAL SPASMS AND DILATATION OF THE OESOPHAGUS.

At the opening of the Gesellschaft der Aerzte, Heyrovsky exhibited a patient from Hochenegg's clinic, who had suffered from chronic spasms of the heart with extensive dilatation of the oesophagus. The patient had been treated for 14 years with Gussler-Gottstein's dilator to relieve the spasms, but without success. Sounds of different construction had been used from time to time, but with no better effect. A year ago he was taken into hospital as the inanition was so painfully evident that something must be done, and gastrostomy was performed. Feeding through the fistula did very well, as the patient put on 10 kilograms. In January of this year the idea of a suture passing from the gastral opening to the mouth was conceived, and a balloon attached to it, so that it could be passed into the stricture from below and dilatation effected. After three months' treatment with soundings, the lumen is now distended to 20 centimetres. It is six months since the last operation was performed, but the patient is able to swallow all kinds of food without the least discomfort. In the six months he has put

on 10 kilograms of body weight, although the wound is not allowed to heal up yet.

URETHRAL FISTULA.

Bachrach brought in a patient from Zuckerbandl's ward, who had a fascial-plastic operation performed on the penis. The patient was 18 years, and had suffered from this dehiscence of the ventrum of the penis for eight years. The ventral opening in the urethral wall was in the middle of the shaft, and had been caused by the careless tying of the organ destroying the circulation, and producing gangrene and necrosis. The dorsal side of the urethra was entire, and the mucous membrane continuous. Rawing and stitching the mucous membrane was first performed, then an excision of a fascial flap taken from the upper part of the thigh and fixed with stitches over the mucous membrane, that had been drawn together. The wound healed per primam, and has now made a good recovery. He further stated that he had met with great success with this fascio-plastic operation in hernia, where it had frequently occurred.

STUTTERING.

Fröschels gave a pathological description of stuttering which he considered physical and mental. Among the physical symptoms deviation of the tongue was a serious defect, being drawn back on one side by hypertrophy. Again, the hemi-hypertrophy of the lips and muscles of the cheek caused a spasmodic movement. These were only physical adjuncts to the functional disturbances which appear as tonic and clonic spasms. The breathing deviates from the normal, both in rhythm and intensity. Another important factor is the functional disturbance of the nervous system, as indicated by the patella and reflex of the jaw; but when patient is alone, he can speak fairly well. Many have a dread of special words and sounds, and are afraid of imitation, and may affect other children. Heredity must also be considered in these cases, as the tonic and clonic movements depend largely on the nerve system in the vocal apparatus, which is clearly marked by the loud expression of some distinct letters or consonants, or the pressing in of words or embolophasia. Stern said he found in many cases of stuttering asymmetry of the face in the form of degeneration, and also the stuttering was bad when alone, and worse after a pause of thinking, which he thought was the exciting cause. Friedjung said many of these children developed a stuttering habit by fondling parents and pampering the child, which could be easily corrected if properly educated. Fröschels said that Stern's observations applied to the hypertrophy he mentioned at the beginning. The stuttering, when alone was mostly after thinking when attempting to correct himself, but he had one case where the thinking corrected the stuttering altogether.

UNITED STATES OF AMERICA.

Washington, Oct. 12th, 1912.]

INTERNATIONAL CONGRESS ON HYGIENE AND DERMATOGRAPHY.

(Concluded.)

THE section dealing with

CHILD HYGIENE

produced a large volume of papers, some of which were quite exceptionally good, and were referred to in my last report. Among the best papers in this section were several by women. Dr. Mary Sutton Macey, of New York, contributed a paper on instruction in child hygiene. Dr. Grace Kimball, of Poughkeepsie, discussed the hygiene of the teacher. Drs. Caroline Hedger, Louise Montgomery, and Caro McArthur, gave the results of studies of a large number of the school children of the stockyards district of Chicago.

Perhaps the most important meeting of the Congress was that of the joint sessions of the sections of

HYGIENIC MICROBIOLOGY AND PARASITOLOGY,

and of the control of infectious diseases. This meeting was really a symposium on poliomyelitis, in which some of the greatest authorities in the world took part.

Dr. Netter, of Paris, dealt with the ætiology of poliomyelitis and phophylactic measures; Dr. Francis Harbitz, of Christiania, Norway, discussed epidemic poliomyelitis in Norway. Sanitary measures against the disease were debated by M. Levaditi, of the Pasteur Institute, Paris; Dr. Karl Landsteiner, Vienna; Dr. Simon Flexner, Rockefeller Institute, New York City; Dr. Paul Romer, Marburg, Germany; and Dr. M. Neustaedter, New York City. On the whole, the most valuable contribution to the meeting, and one of the most valuable contributions to the literature of the subject was made by Professor Alfred Petersson, of Stockholm, Sweden, who gave a *résumé*, or rather an epitome, of the results of the investigations undertaken by him and colleagues for the State Medical Institute of Sweden. Dr. Petersen and co-workers found that the disease is mainly conveyed by direct transmission, and that the naso-pharynx is the means of entrance of the virus. These investigators are of the opinion that flies are a negligible quantity in the transmission of disease.

TROPICAL HYGIENE.

was another vastly instructive part of the Congress. Of course, malaria was fully dealt with. Dr. Harald Seidelin, of Liverpool, propounded a theory as to the causation of yellow fever, which found little favour with American army authorities. He stated that he regards yellow fever as due to *Piroplasma flavigenum*, and transmitted by *Stegomyia fasciata*. He thinks it is probable that microbe-carriers exist in yellow fever as they do in the very similar disease babesiosis. Hookworm disease was thoroughly discussed, and Surgeon-General Rupert Blue, U.S. Public Health Service, read a paper on the municipal control of plague. Military and Naval hygiene was fully considered. Lack of space will not permit a more exhaustive review of the very numerous, voluminous, and occasionally important papers read at the Congress. It may be said that no epoch-making discoveries were announced.

The lesson to be learned from the meeting was that the next step is to apply the knowledge already gathered. We know enough, if properly applied, to very greatly reduce the death rate, and to diminish the occurrence of disease. An educative campaign is now needed to hammer into the heads of the public the laws of health. Hygienic teaching should be made popular, and the elementary laws relating to the care and protection of children, the methods by which infectious diseases are spread, and, above all, the modes of life calculated to ensure health, should be drummed into the ears of mothers and children. A congress like the one just held in Washington is chiefly useful as a means of wide advertisement, not of the individual who reads a paper, but of the matter contained in the papers relating to public health.

An hygienic exhibition was held in connection with the Congress, which was excellently descriptive of subjects concerned with health. Over one part of this exhibition, however, discussion waxed hot and furious. One of the exhibits illustrated various phases in the progress of syphilis, and was denounced by a medical man from New York as no more nor less than a veritable chamber of horrors. The argument of those who were responsible for the somewhat gruesome collection, was that it was in a high degree educative. The reply of those who objected to it was that, although fearful to behold, it was not necessarily deterrently educative, but rather appealed to the love of the morbid, which is inherent in most human beings, and, moreover, tended to harm any young people who witnessed it.

The exhibit was closed but the discussion thereof is by no means closed.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

EDINBURGH.

MENTAL DEFICIENCY BILL.

A DEPUTATION from the various District Lunacy Boards in Scotland has waited on the Lord Advocate, to lay before him certain questions raised by the ap-

plication of the Mental Deficiency Bill to Scotland. Among the points of medical interest raised was the question whether defectives who had come under the Inebriates' Act should be treated under the new measure, the view of the deputation being that such should not be the case. The other suggestions made were of a purely administrative nature.

EDINBURGH ROYAL INFIRMARY AND THE INSURANCE ACT.

It will be remembered that during the summer the staff of the Infirmary made representations to the Board of Management as to the treatment of insured persons in the Infirmary, and that in consequence the Managers passed a series of resolutions declaring in effect that unless urgently requiring hospital treatment, insured persons were ineligible for admission to the infirmary or its out-patient departments. At a recent meeting of the Board notice was given of motion to rescind these resolutions; but when the motion came up it found no seconder, and the managers adhered to the determination arrived at. Moreover, in all the circumstances, they decided that the discussion should be taken as public business, and that a full report of the resolutions questioned should be sent to the Press.

THE INSURANCE ACT AND THE MEDICAL PROFESSION IN EDINBURGH.

The financial proposals of Mr. Lloyd George have done nothing to render the regulations more palatable to the profession in Edinburgh, nor to make them alter their decision to stand out from service under the Act. The conditions attached by the Chancellor to his increased offer are regarded as peculiarly objectionable, particularly the reports required, and the implied inspection and supervision. A meeting of the local division of the B.M.A. has been summoned to consider the instructions to be given to the representatives, and there is practically no doubt that the decision will be to stand out against serving under the Act. As to what will actually happen in relation to clubs after January 15th, no one is yet in a position definitely to say; but the belief among those who have resigned their appointments is that after that date they will attend former club patients on the same terms as their ordinary patients of the same class. It seems as though the system of club practice has received its quietus in Edinburgh, through the agency of the Insurance Act.

GLASGOW.

GLASGOW UNIVERSITY COURT—QUESTION OF INCLUSIVE FEES.

At the meeting of the Glasgow University Court, held on November 7th, communications regarding the question of the inclusive fees were read from the Courts of St. Andrews and Aberdeen Universities, and from the Senate and General Council of Glasgow University. St. Andrews University intimated that they had adopted the recommendations of the Conference of the Courts of St. Andrews, Glasgow, and Aberdeen, and had arranged to introduce inclusive fees in medicine and applied science at the beginning of the academic year. Aberdeen University approved generally of the recommendations. The opinion of the Glasgow Senate was that the Faculty of Science was in general agreement, and the Medical Faculty, also; but the General Council represented that further inquiry was necessary, both as to the amount of the fee and its bearing on extra-mural schools, which had in the past co-operated so efficiently in the training of medical students. No communication on the subject was received from Edinburgh, and Sir David McVail said that, seeing that Edinburgh refused to commit themselves, he wondered whether it was worth while considering the matter at the beginning of the session, since the Treasury had stated that they were not going to give the remainder of the money until the four Universities had adopted the inclusive fee in medicine. Principal McAlister remarked that medicine clearly was going to be a difficulty, and suggested that a small committee be appointed to look into the matter. Sir David MacVail said that, in his opinion, Glasgow was much more closely associated with Edinburgh in this matter

than with Aberdeen or St. Andrews. In Edinburgh extra-mural teaching was at its acme, and in Glasgow it was increasing, whereas in the other Universities there was little or no extra-mural teaching. Edinburgh, so far as he could learn, was going to have nothing to do with an inclusive fee, and he thought they should let the subject alone until they knew definitely what Edinburgh was likely to do. After further discussion, in which the Principal, Professor Gray, and Professor Muir took part, it was agreed to appoint a committee to consider the matter and report.

MEDICAL CERTIFICATES AND THE SCHOOL BOARDS.

The newly-formed Monkland Medical Association passed a resolution to the effect that they would not grant medical certificates in cases of children not attending school unless the School Boards pay for them, and thus a difficulty has arisen in the Airdrie district. The cause of this is stated to be that certain of the Boards insist on the certificates containing the Soul and Conscience Clause, and thus being the same as are produced to the Court. These Boards maintain that if such certificates are produced to them prosecution of the parents would be unnecessary, otherwise they have no alternative but to bring the parent into court, and the parent has to bring the doctor at his own expense to substantiate his defence. Several cases came before Sheriff Lee recently, and the state of matters being explained, the Sheriff said he had nothing whatever to do with the dispute between the Boards and the doctors, neither of whom needed any assistance from him; but he thought parents should be protected from needless expense and trouble. He did not think that in order to settle the issues between two bodies such as the Medical Association and the School Boards, people should be put to the expense of losing a day's work and incurring expense, and if he could devise some method of protecting the parents against such a hardship he should do so.

PAISLEY DOCTORS AND THE INSURANCE ACT.

The Paisley medical practitioners have had under consideration their position in relation to the Insurance Act, and, on the motion of Dr. John Holms, have decided to work under the Act; but it has been considered advisable not to officially notify the local secretary, Mr. T. Hunter, until after the meeting of the British Medical Association next month.

BELFAST.

THE BABIES' HOME.

An excellent institution was founded in Belfast last year by the Children's Aid Society—a Babies' Home. It serves two purposes, as it is not only a home for the children who come under the care of the Society, but it is also a training school for nurses, who receive practical instruction from the matron, and lectures from the medical staff. There are at present twelve probationer nurses, and five others who have completed their training have found ready demand for their services at £25 per annum. At a meeting held in the Home last week, Dr. Henry, Dr. Rusk, and Dr. Dr. J. Shaw spoke in the highest terms of the equipment and work of the institution, and the admirable training which the nurses receive. The superintendent of the Children's Aid Society said that in the nine months during which the Home had been working, 77 children had been admitted, of whom 39 were still in, 18 had been restored to friends, 13 had been boarded out, two adopted, three sent to hospital, and two died. On the basis of a payment of £1 per month for each child, in addition to the fees paid by the nurses for their training, the Home was expected to be self-supporting.

BELFAST GUARDIANS AND MEDICAL OFFICERS' SALARIES.

The Infirmary Committee of the Belfast Guardians have been considering the resolutions of the Belfast Medical Guild, that in their opinion no locum tenens to any dispensary appointment should receive less than five guineas per week, and that the minimum salary for a resident medical officer should be £140 per annum. The Committee received a deputation from the Guild, and also inquired about the salaries paid by other Boards, and eventually they have recom-

mended that in future the minimum salary for resident medical officers at the Workhouse Infirmary, and at the Abbey Sanatorium, be £130 per annum, rising by annual increments of £10 to £150, and that the question of the payment of locum tenens in dispensary districts be referred to the Committee under the Medical Charities Act, for consideration and report. The deputation from the Guild thanked the Committee, and expressed satisfaction with their proposals, and also with the decision of the Guardians to prohibit canvassing for appointments of resident medical officers.

MATERNITY NURSING SCHEME.

At the last meeting of the Londonderry Board of Guardians, the circular which is being sent to Boards of Guardians by the Countess of Aberdeen, on behalf of the Women's National Health Association, was received. It recommends a scheme for the provision of qualified midwives to attend maternity cases entitled to maternity benefit under the National Insurance Act. Dr. Thomas MacLaughlin, who presided, said he could not approve of the scheme, on account of the dual management proposed, the Women's Health Association having part control over the midwife. After some discussion, it was decided by a large majority to take no action in the matter. At several other meetings of Boards, such as Ballymena, Coleraine, and Clogher, similar resolutions have been passed. It is evident that the circular is meeting with a very cold reception in Ulster.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE ANTISEPTIC TREATMENT OF PHTHISIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—In the letter you were so kind as to insert in the MEDICAL PRESS AND CIRCULAR, November 6th, there is a mistake in the printing which I beg to correct. The word "reports" in the sentence "for when the reports of the old Pharmacopœia were excluded from the recent editions" ought to have been "vapores," for the chief object of my letter was to direct attention to the scientific use of antiseptic vapours in the treatment of pulmonary phthisis. The simple fact that pure phenol enables us to carry out this principle deserves attention; for when a solution of pure water with 1 per cent. of phenol added is converted into vapour by boiling, we have an antiseptic agent of definite strength, which can be inhaled so easily and persistently that we have no difficulty in carrying out antiseptic principles in the treatment of lung diseases. It seems very doubtful whether sanatoria are likely to prove of any practical use, for the collecting of tubercular cases in any number in the same buildings or wards must rather tend to produce an atmosphere that is not a pure and healthy one, and is not consistent with open-air treatment.

I am, Sir, yours truly,

ROBERT LEE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the interesting letter which Dr. Robert Lee contributes to your current issue he repeats a statement which, if my memory serves me rightly, he has more than once before put forth in your columns, namely, that "no antiseptic treatment (of phthisis) has been tried in a proper and scientific manner, and till it is we shall see no great change in the morbid effects of tuberculosis in this country." Dr. Lee does not believe in the administration of antiseptic remedies through the stomach; he alludes obviously to inhalation only. It would be very valuable if Dr. Lee would kindly explain exactly what he means by "a proper and scientific manner," and if he would indicate the therapeutical agents which he would recommend for trial. Can he name any agent which could be inhaled without injury or danger, whilst powerful enough to

destroy tubercle bacilli, and to bring the septic spots or cavities in the lungs into a condition in which healing must follow. If he will be good enough to furnish the fundamental practical data necessary for a start I can assure him for myself and colleagues that we shall not lose an hour in putting the treatment to the test. It would be possible to carry out the method in every sanatorium; to provide inhalation chambers filled with an antiseptic atmosphere, in which the patients might remain for hours or days. The question of inhalation cannot have escaped the attention of anyone constantly engaged in the treatment of pulmonary tuberculosis, and we all know that so far it has not gained any recognition as a curative process. Even the quacks seem to have given it up in late years.

I am, Sir, yours truly,
SANATORIUM OFFICER.

London, W., November 7th.

THE TURKISH DEBACLE, AND THE NATIONAL RESERVE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The fate of the National Reserve hangs in the balance. The next few months must decide whether it is to die out—a well-meaning but abortive attempt to keep in touch with the men in the country who have had a military training—or whether it is to be made so great a reality that the country will not allow the military authorities to neglect it, even if they wished to do so. The National Reserve now numbers about 170,000 men. It can be doubled—*i.e.*, brought up to 340,000 men—if all the counties in Britain do as well—and there is no reason why they should not do better—as London, Edinburgh and Surrey. But if it is doubled it is as certain as anything human can be that the Government will find the movement too big not to be taken seriously, and they will feel obliged to provide the men on the register with uniforms and rifles—absolute necessities should a call ever be made upon their patriotism. Numbers alone will force the authorities out of their present attitude of benevolent indifference.

To be specific, I want to ask those of your readers who are eligible to send their names and addresses (stating distinctly the county or town in which they live), their ages, and the corps in which they served, to the *Spectator* Office, London. These replies shall be sorted out and sent to the Secretaries of the various Territorial Associations in whose area the men reside.

There are probably thousands of men who still do not know what the National Reserve is. May I explain by quoting the words of the first paragraph of the National Reserve Regulations:—

“The National Reserve, which forms a part of the military organisation, is primarily a register of trained officers and soldiers who, being under no further obligation for military service, . . . are organised under the auspices of County Associations, and encouraged by the military authorities with a view to increasing the military resources for national defence.”

Every trained man and trained officer is eligible. Here is the form which I suggest your readers who are eligible should fill in and post:—

FORM.

I desire to join the National Reserve.

Name in full

Address in full

Age

Former Corps

War Service (if any)

I am, Sir, yours truly,

J. ST. LOE STRACHEY.

[The foregoing may appeal to medical men who have been in the regular or volunteer army service.—ED. M.P. AND C.]

OBITUARY.

MR. ARTHUR HENRY BENSON.

We regret to announce the death, which occurred on the 6th inst., of Mr. Arthur Henry Benson, the well-known Dublin ophthalmologist. A son of the late Prof. Charles Benson, M.D., Mr. Benson had a distinguished College career. In the year 1875 he graduated B.A. of Dublin University, and the following year took the degree of M.B. Ten years later the degree of M.A. was conferred upon him. In 1881 he became a Fellow of the Royal College of Surgeons in Ireland. Mr. Benson had been for many years one of the leading ophthalmic surgeons of Dublin. He was Surgeon to the Royal Victoria Eye and Ear Hospital, and Aural and Ophthalmic Surgeon to the Royal City of Dublin Hospital. He was a frequent contributor to the literature of his speciality, and many of his papers have appeared in our columns. He took particular interest in the proceedings of the Royal Academy of Medicine in Ireland, and was President of its Pathological Section in 1909-1911.

In private life he was a man of singular charm and modesty. He was interested in outdoor sports, and was a keen golfer and an experienced yachtsman. It was known for more than a year past that his health had broken down, but his friends hoped that with care and rest his life might have been prolonged. Unfortunately, these hopes have been disappointed.

We offer our sincere condolences to his widow, and to his brother, Sir Hawtrey Benson.

REVIEWS OF BOOKS.

THE DIFFUSION OF SMALL-POX. (a)

THE writer of this booklet is also the author of the article on small-pox in both the first and second editions of Quain's "Dictionary of Medicine"; besides having produced "various papers, translations and reports on small-pox, on fever, and on small-pox hospitals in relation to public health." Such a record should surely go a long way towards constituting satisfactory testimony of the fitness of his preliminary training, and of the ardour with which he pursued his opportunities, as well as of the enthusiasm with which he endeavours to give the professional public the benefit of his collective experiences. Such contributions to the fund of general knowledge, emanating from the pen of a trained and earnest expert, are always worthy of the best attention of our readers. They form the best adjuvant to, and substitute for, immediate personal experience, which can in no instance be absolutely universal.

Our author's object in the preparation of this monograph is, as he himself tells us, to show that the hypothesis of "distal aerial dissemination is unsupported by the evidence, and that those who initiated and organised the small-pox and fever hospitals of London rendered an inestimable service, not only to London but to the world." A view of so very considerable interest to both the lay and the medical public should surely receive the most careful attention—more especially when defended, as in the present instance, by an expert of exceptional experience. We would express, in conclusion, the earnest hope that the collective researches of accomplished and enthusiastic investigators of the clinical nature and epidemic incidence of small-pox will in the near future come to be focussed so effectively on the great central question, which has hitherto successfully evaded solution as to lead to the discovery of the causative microbe of this deadly and still mysterious plague. It is rather strange, indeed, as well as disappointing, that the primordial germ of one of the diseases which presents most distinctively the leading features that would be theoretically regarded as characteristic of microbic infection has hitherto

(a) "Small-Pox and Its Diffusion." By Alexander Collier, M.D., ABERD., M.R.C.P., etc. Bristol: John Wright and Sons, Ltd. 1912.

proved to be refractory to all known methods of investigation. Let us hope that it may prove one of the early conquests of our twentieth-century ultramicroscopic methods of research.

MEDICAL NEWS IN BRIEF.

Dental Hospital, Dublin.

THE annual meeting of the Incorporated Dental Hospital of Ireland was held last week, in the Hospital, Lincoln Place. The annual report stated that the new departure which marked the year ending September 30th last, was the generous grant of £150 to the Hospital by the Dublin Corporation. To extend the amount of purely gratuitous work for the city poor, which the grant made possible, it was decided to start a free dispensary, to be open on three evenings in the week. Though all means were taken to extend the knowledge of the dispensary among the poor, its advantages were so scantily availed of that, after an extended trial, the Board decided to discontinue it, and instead to make the morning dispensary free. In taking that step the Board had foregone a source of income which last year had brought in £90. It was believed that that must extend very largely the scope of the Hospital's benefits, and afford stronger grounds for appeal to the charitable public. The total number of cases treated in the hospital amounted to 47,212, of which 16,070 were dispensary cases, and 21,187 extractions under anaesthetics. The chief feature of the year's free work was over 600 fillings, nearly 1,000 advice cases, and 3,837 extractions. The balance sheet showed that while there was a satisfactory increase of £45 10s. in subscriptions and donations, the contributions had fallen £120. The report of the Dental School mentioned that the total number of pupils was 47, of whom eleven were exclusively engaged in prosthetic work, nine were combining the remainder of their prosthetic pupilage with their dental practice, three took short additional courses of prosthetic instruction, twenty were exclusively engaged in their dental hospital practice, and four took short additional courses of practical dental surgery. During the session the Dean of one of the largest London dental hospitals made a special inspection of the school and presented a report to the Department of Technical Instruction, for which he acted. He commented very favourably on the fittings and accommodation, the teaching, and the work of the students.

Dublin Clinical Hospitals and Instruction in Tuberculosis.

A DEPUTATION of medical men, representing all the general clinical hospitals of Dublin, waited on the Local Government Board last week with reference to the proposed teaching of tuberculosis treatment under the Insurance Act.

This teaching has been carried on at the Charles Street Dispensary by the staff, and the L. G. Board have signified the recognition and sanction of that course in view of the appointments throughout the country. Several of the members of the deputation, we are informed, held that the work which was being done by the Charles Street Dispensary should, more properly, be undertaken and carried out by the general hospitals. The reply of the Board to the arguments submitted will be furnished in due course.

The Mass Meeting of the Profession in Manchester.

MR. G. A. WRIGHT, F.R.C.S., presided at a mass meeting of medical practitioners in the Midland Hall, Manchester, on Saturday last, to consider the present situation created by Mr. Lloyd George's latest proposals.

Mr. E. B. Turner, F.R.C.S.Lond., proposed, and Dr. T. Wheeler Hart (Manchester) seconded, a resolution declaring that the conditions of service laid down in the regulations were intolerable, notwithstanding Mr. Lloyd George's new proposals, and would destroy for ever the independence of the profession. The resolution advised the refusal of any financial offer until the conditions of service were made compatible

with the best interests and honourable position of the profession.

The resolution was supported by Dr. Reynolds (Manchester), Professor Murray (Manchester), Dr. Trotter (Huddersfield), and Dr. Mannix (Lancaster), and carried unanimously.

The second resolution, moved by Mr. F. H. Westmacott (Manchester), and seconded by Dr. C. E. M. Lowe (Crewe), was to the effect that members of the British Medical Association present should instruct their representatives to the Representative Meeting that any failure on the part of that meeting to give effect to the original demands of the profession would inevitably result in independent action being taken.

Other Meetings of the Profession.

AT a meeting of the City Division of the British Medical Association (which includes the City of London and the Boroughs of Finsbury, Bethnal Green, Shoreditch, Hackney, and Stoke Newington), held last week, attended by more than half the doctors practising in these areas, it was unanimously resolved to refuse to accept Mr. Lloyd George's terms and to decline to work the Act. The representatives appointed to attend the Representative Meeting next week were instructed in this sense. The doctors of the St. Pancras division, which includes St. Pancras, Islington, Holloway, and Highgate, have decided by 88 to 14 to refuse to work the Act.

At a representative meeting of medical men of Lincoln and a large part of Lincolnshire it was decided, almost unanimously, not to work under the Insurance Act unless the cardinal points as originally stated by the British Medical Association are conceded. The delegate of the division to the forthcoming special Representative Meeting was instructed to vote in accordance with this decision.

The Hampstead Division of the British Medical Association on Monday last resolved by 37 votes to six not to work the Insurance Act under present conditions; and instructed its representative to vote in accordance with this decision at the Representative Meeting. The meeting afterwards passed by a large majority a resolution declaring that to accept Mr. Lloyd George's offer would be "to undertake an inefficient service, to sell the freedom and to degrade the status of the profession."

At a meeting of the West Norfolk Division of the British Medical Association it was also unanimously resolved not to accept Mr. Lloyd George's terms.

Peamount Sanatorium—Malicious Injury Claim.

LAST week, before the Right Hon. the Recorder of Dublin, Messrs. Humphreys, Ltd., contractors, claimed from the Dublin County Council £800 in respect of the malicious destruction of the sanatorium at Peamount, near Dublin, on the 21st July last. Having heard evidence, the Recorder awarded £220.

University of Oxford.

In a Congregation held on November 9th, the following degrees were conferred:—D.M.—A. H. Hogarth, Christ Church, and M. Davidson, Trinity.

University of Cambridge.

At a Congregation held on November 9th the following degree was conferred:—M.B. and B.Ch.—F. G. Chandler, Jesus.

The National University of Ireland.

THE following is the successful candidate for the Travelling Studentship (£200 a year tenable for two years).—In Medicine (Anatomy)—Henry L. Barnville, B.A., M.B., B.Ch., University College, Dublin.

SIR SHIRLEY F. MURPHY, F.R.C.S., has been appointed editor of *Public Health*, the official organ of the Society of Medical Officers of Health, in the place of Dr. G. F. McCleary, who relinquished the editorial control of the journal on his appointment as Principal Medical Officer to the National Insurance Commissioners.

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

DR. E. A. (Beds).—The courtesy is usually extended to non-members of a medical society, but only to the extent of speaking in discussion or of examining cases, etc. Visitors cannot take part in voting or any other business proceedings.

LEAGUE OF MERCY GRANTS TO HOSPITALS.

With the sanction of Prince Alexander of Teck, Grand President of the League of Mercy, grants for 1912, amounting in all to £2,315, have been made to extra-metropolitan hospitals in the league.

The total amount handed over to King Edward's Hospital Fund for London is now £170,000, in addition to which £12,076 has been given to extra-metropolitan hospitals in counties collecting for the league.

L. S. A. (Blackheath).—The so-called "hunger pain," as described by Moynihan, is most characteristic of duodenal ulcer, being frequently the first symptom. It is also definitely relieved by taking food.

DR. R. R. (Liverpool).—Your communication came to hand as we were "at press."

APPENDICITIS AND AN UMBRELLA.

The conversation turned on surgery, a gentleman relating how a careless operator had stitched up a sponge in a wound. Another said it was not an uncommon occurrence, and a third offered his opinion that in the case of death under such circumstances the doctor should be found guilty of manslaughter. Then a little gentleman in the corner put down his paper and said, "I wish you wouldn't talk of such things, it upsets me dreadfully."

"How?" inquired the originator of the conversation.

"Well, three weeks ago I was operated on for appendicitis, and only this morning I heard that my doctor had lost his umbrella."—*Short Stories* for November.

INQUIRER (Dundee).—The principal commercial source of thorium at the present day are the monazite sands deposits in Brazil. Purified monazite ought to contain not less than five per cent. of thorium oxide. The growing importance of this element for purposes of gas-lighting was stated the other day by Mr. Edmund White, B.Sc., F.I.C., to correspond to a demand for gas mantles to the extent of 400 millions annually.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, NOVEMBER 13TH.

HUNTERIAN SOCIETY (Westminster Hospital).—4 p.m.: Clinical Afternoon. Cases by Members of the Medical and Surgical Staff. Surgical Cases by Mr. W. G. Spencer, Mr. A. H. Tubby, Mr. E. R. Carling, Mr. J. M. G. Swainson and Dr. P. Stewart. A Demonstration of Clinical-Pathological Methods will be given by Dr. R. G. Hebb and Dr. J. A. Fraxton Hicks.

UNITED SERVICES MEDICAL SOCIETY (Royal Army Medical College, Grosvenor Road, S.W.).—5 p.m.: Col. B. Skinner, M.V.O., A.M.S.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Clinics:—2 p.m.: Throat Operations (Mr. Gillies). 2.30 p.m.: Children's Out-patient (Dr. T. R. Whipple); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 p.m.: X-Rays (Mr. W. Stewart); Clinical Pathology and Pathological Demonstration (Dr. W. H. Dunstan). 5.30 p.m.: Eye Operations (Mr. Brooks).

BROMPTON HOSPITAL FOR CONSUMPTION.—4.30 p.m.: Dr. D. Grant: Special Post-Graduate Course.

THURSDAY, NOVEMBER 14TH.

ROYAL SOCIETY (Burlington House, London, W.).—Papers by Dr. J. W. Cropper, Edith R. Saunders, Prof. A. J. Brown, Mr. F. P. Worley, Mr. R. Kirkpatrick, Mr. J. Thompson, Mr. G. W. Ellis, Mr. J. A. Gardner, Prof. R. B. Thomson and others.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynecological Operations (Dr. A. E. Giles). Clinics: Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 p.m.: Medical In-patient (Dr. G. P. Chappel). 4.30 p.m.: Special Demonstration: Dr. G. P. Chappel: Selected Medical Cases.

BROMPTON HOSPITAL FOR CONSUMPTION.—4.30 p.m.: Dr. M. Paterson: Special Post-Graduate Course.

FRIDAY, NOVEMBER 15TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF OTOLGY) (1 Wimpole Street, W.).—5 p.m.: Cases and Specimens by Mr. Richard Lake, Mr. A. F. Penny, Mr. Ernest West, Mr. Hugh Jones, Dr. Dan McKenzie, Dr. H. J. Davis and others.

ROYAL SOCIETY OF MEDICINE (SECTION OF ELECTRIC-THERAPEUTICS) (1 Wimpole Street, W.).—8.30 p.m.: Professor Jellinek (Vienna).

CHILD STUDY SOCIETY, LONDON (Royal Sanitary Institute).—7.30 p.m.: Mmc. Pujol-Segalas (Paris).

BROMPTON HOSPITAL FOR CONSUMPTION.—Expedition to Frimley, leaving Waterloo at 1.15 p.m. Demonstration at the Sanatorium by Dr. Wethered.

Appointments.

CRIBB, H. G., M.R.C.S., L.R.O.P.Lond., Medical Superintendent at the Durham County Asylum.

EGAN, JOHN, L.R.C.P. and S.Irel., Senior Resident Medical Officer at the Guest Hospital, Dudley.

LASLETT, WILLIAM H., M.B., Ch.B.Viet., House Surgeon at the Maternity Hospital, Whitworth Street West, Manchester.

PARDOE, J. G., M.B., M.S.Aberd., Surgeon to the West London Hospital.

PURCELL, N., M.B., Ch.B.Edin., House Surgeon at the Maternity Hospital, Whitworth Street West, Manchester.

Vacancies.

Staffordshire County Asylum, Stafford.—Assistant Medical Officer. Salary £160 per annum, with furnished apartments, board and washing. Applications to the Medical Superintendent.

Kent County Asylum, Maidstone.—Fourth Assistant Medical Officer. Salary £200 per annum, with furnished quarters, attendance, coals, gas, garden produce, milk, and washing. Applications to Medical Superintendent, Asylum, Maidstone.

Brighton, Hove and Preston Dispensary.—Resident Medical Officer. Salary £130 per annum, with board and residence. Applications to the Assistant Secretary, 113 Queen's Road, Brighton.

City and County of Newcastle-upon-Tyne.—Medical Officer of Health and Medical Superintendent of the City Hospitals for Infectious Diseases. Salary £700 per annum. Applications to Town Clerk, Town Hall, Newcastle-upon-Tyne.

Births.

ARKLE.—On Nov. 9th, at Bentham, West Derby, Liverpool, the wife of A. S. Arkle, M.R.C.S., L.R.C.P., of a son.

BAKER.—On Nov. 8th, at Freynes House, North Molton, the wife of F. C. J. Baker, M.R.C.S., of a daughter.

BROADBENT.—On Nov. 7th, at 50 Brunswick Square, Brighton, the wife of Dr. Walter Broadbent, of a son (stillborn).

GREENWOOD.—On Nov. 6th, at "Reigate" Lower Park Road, Loughton, Essex, the wife of M. Greenwood, junr., M.R.C.S., Statistician to the Lister Institute of Preventive Medicine, of a son.

GROGONO.—On Nov. 4th, at Witham Lodge, 171 Romford Road, Stratford, E., the wife of Dr. Eric W. Grogono, of a son.

JONES.—On Nov. 6th, at Clifdene, Cowes, Isle of Wight, the wife of Fleet-Surgeon Murray Jones, R.N., of a daughter.

MEREDITH.—On Nov. 9th, at Haynes, Wellington, Somerset, the wife of R. W. Herbert Meredith, M.R.C.S., L.R.C.P., of a daughter.

SLADE.—On Nov. 7th, at Chernoche House, Fleet, Hants, the wife of John Godfrey Slade, M.A., M.D., B.C.Cantab., etc., of a son.

Marriages.

BLAXLAND-ANDREWS.—On Nov. 6th, at Colney Church, A. Jasper Blaxland, M.S., F.R.C.S., of 2 Surrey Street, Norwich, son of Mr. and Mrs. Blaxland, of Bournemouth, to Marion, only daughter of the late Mr. W. Andrews, of Chediston, and of Mrs. Andrews, Colney.

GILCHRIST-MARKS.—On Nov. 7th, at St. Mary's, Primrose Hill, N.W., James C. Gilchrist, M.D., Cardiff, eldest son of the late Dr. Gilchrist, late of the Crichton Royal Institution, Dumfries, to Emmeline, younger daughter of the late Alfred Marks, Esq., formerly London manager of the London City and Midland Bank, Ltd., and Mrs. Marks, Adelaide Road, Hampstead.

MACKENZIE-BURGOINE.—On Nov. 6th, at the British Consulate and the Guards' Chapel, Cairo, Major T. Campbell Mackenzie, D.S.O., R.A.M.C., Egyptian Army, to Elsie Burgoine, only daughter of the late C. Moyle-Borlase, of Penzance, Cornwall, and Mrs. Borlase, of Aidborough, Norfolk.

ROBINSON-DALY.—On Sept. 30th, at Emmanuel Cathedral, Durban, Francis H. Robinson, B.A., M.B., B.C.(Cantab.), M.R.C.S., L.R.C.P., R.M.O., Bandler Kop, Transvaal, elder son of Mr. and Mrs. H. Robinson, Spilsby, Lincolnshire, to Mary, elder daughter of Captain and Mrs. B. Daly, Beifast (late the Bedfordshire Regiment).

Deaths.

BYRNE.—On Nov. 5th, at Sunwick, East Molesey, and late of Manchester, George Byrne, M.R.C.S., L.R.C.P.Lond., husband of Florence A. Byrne, aged 56.

MAT.—On Nov. 4th, at Bountis Thorn, Finsbury Park, N., Jane, the wife of Lewis J. May, M.R.C.S.

PORT.—On Nov. 6th, at Yalding, very suddenly, Frank Port, Brigade Surgeon, Army Medical Staff, aged 76.

SALT.—On Nov. 4th, at Inglewood, Malvern, Henry Salt, M.D., second son of the late John Salt, Esq., of London, aged 69 years.

STRONG.—On Nov. 6th, at his residence, Sunnyside, Weston, Bath, Henry Barlow Strong, M.R.C.S., L.R.C.P., eldest son of the late Henry Strong, Barrister-at-Law, Middle Temple, in his 71st year.

NOTES AND COMMENTS.

The Suffragist March.

WHATEVER our views of the extension of the parliamentary franchise to women, we must frankly admit that the movement has demonstrated the possession of qualities and resources with which the female sex has not generally been credited. A fine field, for instance, has been opened up in journalism, in public speaking, and in organisation, and there has been no lack of women capable of rising to the opportunity thus afforded. Of certain other physical demonstrations there is no need here to make anything more than a passing allusion. The most recent feat is the march of a small band of suffragists, led by Mrs. Fonblanque, from Edinburgh to London, a distance of 393 miles. We understand that none of the party was obliged to fall out on the march, and that from ten to thirty miles was accomplished on each day's walk. The feat is certainly one that arrests attention. It opens up a new phase of the physical resources of women, although one, of course, calls to mind the romance of Jeannie Deans, who made a similar journey on foot to petition the King for her sister's pardon. Henceforth we may expect women to invade every field of athletic sport, for nothing of the kind can be closed against a competitor who can walk from Edinburgh to London within a reasonably short time.

The Dress of the Walkers.

THERE is much to be proud of in their performance, for the women who are equal to it should be fit mothers of a race noted for strength and endurance. Writing for medical readers we may perhaps be pardoned for calling attention to another side of the matter—namely, that of feminine dress. It may reasonably be assumed that high-heeled shoes were not popular in this long-distance march; neither were tight corsets, small waists, and loose, long skirts much in evidence. If the suffragists can lead the fashion in feminine dress so as to shear away some of its monstrosities the world at large would probably be more ready to put up with any little foibles in other directions. The large hat is still with us, but the hobble skirt appears to have gone the way of all of women's extreme fashions. One gew-gaw we have noted lately is particularly grotesque—namely, the long feather fixed at a right angle from the side of the hat. Any woman carrying such a decoration takes up exactly twice the room to which she is entitled, and becomes a general nuisance in street, church, railway carriage or other place of public resort. Let us hope that the suffragists' example will influence feminine fashions in time to prevent the necessity of passing sumptuary laws by a man's parliament.

Food and the Sanatorium Benefit.

WE are glad to note that after considerable pressure brought to bear on the Irish Insurance Commissioners, they have been persuaded to agree that insurance committees are entitled to provide food and clothing in the administration of the sanatorium benefit. In other words, the Commissioners have assented to the view that the word "treatment" includes these necessities. We understand that the English Insurance Commissioners are taking the same view. It was obvious enough that if any good was to be done by domiciliary treatment in tuberculous cases, instances would arise where the first essential of treatment would be food. But it is not always easy to get Government officials to see the obvious. Much credit is due to the insurance committees, notably those of the city and county of Dublin, for the pertinacity with which they have pressed their point in face of the opposition both of the Insurance Commissioners and of the Local Government Board.

Sparing the Rod.

AT first sight it would seem as if the fear of inflicting too much punishment upon the growing child had caused the pendulum to swing in the opposite direction, leading a certain section of the teaching profession to refrain from correcting or reproofing their wayward scholars in the slightest degree. The reign of terror that once prevailed in young people's "seminaries," as depicted so graphically by Charles Dickens, is, happily, a thing of the past. Corporal punishment is now comparatively seldom administered, and in public elementary schools, at any rate, teachers have to be content with the lightest caning, or they run a serious risk of an action for assault upon the part of irate parents. To such an extent has the policy of sparing the rod arrived that a system of education has actually arisen the central feature of which, so far as we understand it, consists of a new type of discipline, based on self-control, and voluntarily imposed by the children upon themselves. At the joint conference of the Child Study Society of London and the Montessori Society of the United Kingdom, held last week at the Royal Sanitary Institute, the principle of the Montessori system was explained. The inventor of this remarkable method of education, Dr. Montessori, the first Italian lady physician, claimed that discipline is secured by enfranchising liberty, and not by punishment or rewards. The results of the teaching, according to its exponents, are said to be of great value in enabling young children speedily to acquire control of all voluntary movements, including those necessary for the "three R's." It remains to be seen whether this new

system will spread in this country as it appears to have done in the land of its birth.

The Cholera in Turkey.

A CROWNING disaster has fallen upon the Turks in their fight against the Balkan States, in the shape of an outbreak of cholera. Large numbers of persons are attacked daily, and the death roll has been and is likely to continue enormous under the present conditions of wide-spread famine and of the depression of defeat. In Constantinople itself there can be no hope of feeding the healthy refugees, still less of nursing the sick. The outlook for the city, indeed, is at present one of the blackest that the human mind could contemplate. The curtain seems likely to go down ere long upon a scene of horror unparalleled in the history of the world. For a backward country like Turkey cholera is always more or less in the air. During the Crimean war the allies suffered heavy losses from that disease. The wide area covered by the present epidemic suggests that the water supplies are extremely contaminated. Under these circumstances it may be a wise policy for the Bulgarians to halt at the lines of Chatalja, for if they go on to Constantinople they are walking into the jaws of a remorseless enemy. Brave men are not proof against cholera, and if the victorious Bulgarians bivouac in Constantinople they are likely to lose more men from the onslaught of the cholera vibrio than they have lost in all their dearly-bought victories. Far better they should stop at Chatalja and boil their drinking water.

LEADING ARTICLES.

THE INSURANCE ACT AND THE MEDICAL PROFESSION.

DURING the past week the dispute between the Government and the medical profession has developed into a situation which leaves little or no hope of a compromise. Meetings of the local divisions of the British Medical Association have met throughout the Kingdom and have given their answer to the latest proposals advanced by Mr. Lloyd George. In the overwhelming majority of cases the instruction to the local Representative and the Representative Council has been definitely to reject these proposals and to refuse to work the Act as it stands. In other words, medical men stand to the cardinal points laid down at an early stage of the dispute. These local declarations must, of course, pass through the hands of the Representative Council and receive their approving resolution before they assume the status of a declared policy. To all intents and purposes, however, it is to be presumed that the Council in this matter will simply act as a body for registering the decision of its constituents. With little hesitation, therefore, we may conclude that the Insurance Act has been rejected by the medical profession. At the same time it seems clear that a considerable body of opinion exists in the Divisions in favour of an attempt to secure more favourable terms. Should the Council decide to undertake negotiation with that end in view, the utmost it can do to secure the consent of its electorate—so we

gather from the *British Medical Journal* of the 16th November—is by a referendum to divisions. It is to be regretted that some more elastic machinery is not available under the constitution of the Association. The Representative Council held its momentous meeting at the Connaught Rooms on the 19th and 20th instant, under the chairmanship of Mr. Verrall. It is difficult to imagine the state of affairs which will ensue in the event of the rejection of terms and conditions as to medical service under the Act. The situation is unparalleled, and so far as can be reasonably anticipated the balance of advantage should be in the hands of the medical profession, provided they can secure the adhesion of an overwhelming majority of their members. However, no great collective movement has ever yet been brought to a successful issue into which the chances of disloyal secession have not entered. Judging from the signs and portents that are overshadowing the professional horizon, the Christmastide of 1912 is likely to become memorable in the medical annals of the United Kingdom. Although the immediate administration of the Act would fall to one class of practitioners, yet all ranks must be indirectly concerned. Mr. Lloyd George does not appear to have made any serious attempt to grapple with the serious aspects of the relationship between the voluntary medical charities and the insured. Hospital consultants and specialists, as well as salaried medical officers, have practically with one voice declared they will not attend insured persons gratuitously at the hospitals. In rather over a month the medical benefits of the Act will come into force, but even at this late hour no terms have been made with the profession that must administer those benefits. The procrastination which has marked this controversy is not as a rule characteristic of the methods of Mr. Lloyd George. The delay suggests, as it has often done before, that he may be provided with some alternatives with the help of which he hopes to checkmate his opponents. Whatever may be the outcome, we sincerely hope that he will not succeed in splitting that unity of the medical profession which is the one consoling feature in the present crisis. Within the next few weeks or months events will probably put to the test the individual loyalty of the majority of the medical men in the United Kingdom.

CURRENT TOPICS.

The London School of Tropical Medicine.

THE members of the City Sub-Committee for the Rubber Trade have recently issued an appeal on behalf of the Lord Mayor's Fund, formed with the object of raising a sum of £100,000 for the endowment and extension of the London School of Tropical Medicine. The circular, which urges the claims of the school on all those interested in the production, manufacture, and sale of rubber, says: "All who are connected in any way with a tropical cultivation such as rubber—whether directly, as planters and suppliers of their machinery and tools,

or indirectly, as manufacturers relying on the tropics for their raw material—realise that the most important consideration is the health of the men, both Europeans and natives, engaged on the plantations. No one can view with indifference the enormous annual wastage of human life, due to the ravages of tropical diseases, and all connected with plantation rubber must recognise the duty of doing everything possible to improve the health conditions, but we desire to emphasise the fact that this appeal is made on business as well as on humanitarian grounds. The London School of Tropical Medicine was founded with the object of carrying on research into the causes, prevention, and treatment of tropical diseases, as well as to give a thorough training to medical men to enable them to deal, in the tropics or elsewhere, with all forms of tropical disease. Support to this appeal has already been received from various companies engaged in rubber cultivation, and, so far, out of the £100,000 required, approximately £44,000 has been collected; but even the whole £100,000 is a small amount to ask for when the enormous benefits to be derived from improved health are taken into consideration." Considering the enormous demand for rubber, it should not be difficult to raise the required sum in a reasonable time.

Ozone for Public Buildings.

THE adequate ventilation of public buildings still forms one of the most pressing problems of the day. The apparent indifference, amounting sometimes to positive neglect, on the part of those responsible for the airing of covered-in places where masses of people congregate periodically, is a matter for the gravest reflection. Churches and theatres alike suffer, some more than others, from lack of means of replenishing, let alone of even heating, the atmosphere within their walls, the respiration of which often leads to a characteristic train of symptoms which are sometimes erroneously ascribed to anything but the true cause. Natural ventilation is seldom sufficient to render the air of a large building free from any suggestion of stuffiness, and the provision of artificial or forced systems of atmospheric interchange is a costly undertaking. A considerable degree of success has been obtained by the introduction of a system whereby currents of ozone are dispersed throughout the air of a closed space. The public have already made its acquaintance on one of the Tube railways, and the general consensus of opinion is that the travelling along that particular line has been thereby rendered much more agreeable. It should not be impossible to install ozonising plants in all large buildings which, if not directly assisting in the removal of foul air, would, at any rate, impart a freshness to the atmosphere and go far towards the prevention of somnolence and headache.

Business Men and Health.

SOME little stir has been caused as the result of the opinions expressed by certain leaders of the medical profession upon the health of city men at the recent conference upon the subject at the Guildhall. The casual reader of the speeches made thereat might be excused were he to believe that sound health is entirely a matter of diet. An adequate supply of wholesome and nourishing food is, of course, a *sine quâ non* for the maintenance of physical and mental vigour, but it would be a mistake to think that a due observance of dietetic laws constitutes the whole of hygienic law. Faddism in diet is greatly to be deplored, except

when it is compulsorily indulged in by the chronic dyspeptic. The neurasthenic and the hypochondriac also are not lifted out of their respective mental grooves by a daily—or, rather, an hourly—solicitude as to what they shall eat and what they shall drink. Every man of discretion ought to know by experience what suits his digestion and what he ought to avoid, and it is of little use to lay down any universal law as to eating, seeing that, in matters of diet, most people are a law unto themselves. The value of fresh air, of regular habits, and of sufficient exercise, as well as of recreation, needs to be impressed quite as much upon city workers as that of proper food. It would be well in conferences of this character to invite prominent laymen to express their views upon the subject, as was done not long ago in connection with a discussion on tropical medicine. Restaurant and tea-shop proprietors might also, with advantage, participate in meetings at which opinions upon matters affecting the health of a large number of their clients are ventilated.

Automatism.

A PRISONER of good social position and of good character was tried at the late Derby Assizes and sentenced to two months' imprisonment for the theft of a motor car. There seemed no adequate motive for the theft. The case is remarkable only for the novelty of the defence that was raised. This was based on the theory, which it was urged had been scientifically established, that in certain cases of unstable nervous equilibrium an individual passes from one personality to another without either the power to prevent this transition or the knowledge in the primary state of what was done in the secondary. Dr. Hyslop, called as an expert, described the prisoner's condition from the time of his arrest to the time of the trial as one of mental automatism, which was midway between somnambulism and a minor form of epilepsy. A person so affected, he maintained, could perform complicated mental and physical actions of which he would have no recollection on recovering his normal state. Previous to this testimony the prisoner had declared on oath that he had no recollection of what had happened between leaving his Territorial camp and being in the police cell, a month later. The judge brushed aside this defence, ruling that the question was whether the prisoner knew he was doing wrong when he stole the car, not whether he remembered it some time afterwards.

London Ambulance Service.

IN view of the increasing number of accidents from the motor traffic alone, an efficient ambulance service is one of the most pressing needs of the day in London; and it is with regret we learn that this cannot be supplied until the County Council shall have obtained from Parliament power to co-ordinate the existing material. This may involve a delay of many months, since the matter cannot be brought forward until next Session. Adopting the conclusions of a Sub-Committee, the Council agrees that there does actually exist at the present time in London material which, with efficient organisation, would furnish an adequate service. The Local Government Board, however, has declared that, while they approve of the principle of a united ambulance service they have no power to authorise the utilisation of the ambulances provided by the Asylums Board, the Port of London Authority, the borough councils, or the boards of guardians, and that legislation will be necessary. With regard to existing and available material we learn that the Metropolitan Police

maintain 336 ambulances for use in street accidents. The Port of London Authority is effecting great improvements in its ambulance facilities, and when complete the service will consist of four motor ambulances, 41 litters and litter under-carriages, 43 stretchers, and 38 awnings. The Asylums Board possess eight ambulance stations, 62 horse-drawn ambulances, 17 petrol-driven ambulances, and 11 petrol-driven omnibuses capable of adaptation for use as ambulances. Ambulance services besides these are kept up by the principal hospitals, the borough councils, the Asylums Board and boards of guardians; altogether a small army, which needs to make it perfect only a responsible commander-in-chief and a staff to carry out his orders.

The Food Value of Margarine.

SUBSTITUTES for staple articles of food, however excellent in themselves, are seldom accepted by the public as the real equivalent for that to which they have been accustomed all their lives. No matter what the chemical composition or nutritive properties of an alternative food-product, its introduction into the domestic larder is apt to be resented in an extraordinary degree. This prejudice is well illustrated in the case of margarine, the well-known substitute for butter. This substance, first prepared in France, in 1870, by its inventor, has practically the same food-value as ordinary butter, with the exception that in the former there is a less percentage of soluble and volatile fatty acids. An amusing discussion as to the relative values of the two substances took place last week at a meeting of the Central (Unemployed) Body for London, owing to the recommendation of the Finance Committee to supply the Hollesley Bay Colony with margarine, at a cost of £96, instead of with butter, at a cost of £228. Some of the members were at once up in arms with indignation at such a proposition, in spite of the fact that the Mayor of Islington, himself a caterer, offered to give five pounds to any charity if those present could discover which of four pats he prepared were margarine and which butter! Fortunately for the exchequer the amendment to substitute margarine was carried by 22 votes to 11. It would be a great pity if an unfounded prejudice were to prevent the more extended use of a wholesome and inexpensive fat in the daily dietary of the poor. The action of the committee may, therefore, be commended as tending to educate popular opinion and to remove a common misconception as to the food-value of margarine.

The Efficacy of Sulphur Lotion.

MEDICAL practitioners who have occasion to prescribe sulphur for external use have often been surprised on account of the variable results obtained with this drug in the form of a lotion. Even with the same formula the active ingredient will seem more energetic at one time than at another. The discrepancy is probably explained by the varying degrees of solubility of the sulphur, by the extent to which it is incorporated with other drugs, and by the degree of acidity of the cutaneous secretions with which it comes into contact. The subject has been ably dealt with by Dr. O. H. Foerster, of Milwaukee (a), who points out that ordinary sulphur does not interchange with the keratin of the horny layer of the skin, both being insoluble. The views of Unna are quoted to the effect that the therapeutic efficiency of sulphur lotions must

depend upon their ability to exhibit sulphur to the skin in such a form that either nascent sulphur or sulphuretted hydrogen, or both, are evolved. Mixtures of lime-water and sulphur, as commonly ordered, do not fulfil this requirement, there being practically no interaction, so that such lotions often give disappointing results when employed in acne or furunculosis. The author concludes that Vlemminck's solution, or liquor calcis sulphurata, prepared by boiling together milk of lime and sulphur, is the most active of all sulphur lotions, because, on coming into contact with the skin, the reaction of which is acid, nascent sulphur in a state of fine subdivision is formed in addition to hydrogen sulphide.

The Favoured First-born.

OUR official belief in the superiority of the first-born is very ancient. Hindu and Hebrew have supported primogeniture from immemorial antiquity, and the feudal system has planted the idea firmly in such legal code as we possess. "Do to others as they would do unto you, but do it first," is a comparatively modern business axiom; it has the sanction of centuries behind it when applied to the art of getting born. The importance of being born first is nowadays often questioned, probably because only one can be the first-born, and there is an overwhelming majority of those who are not so lucky. Although we may suspect the scepticism of the younger son, he has scientific backers. Professor Karl Pearson shows that tuberculosis, insanity and criminality have all a preference for the eldest, and he is supported by other reputable observers. Doubtless the degenerative changes attributed to the peerage are due to this phenomenon. Some of these degenerative traits may be due to environment. The tendency to coddle and pet the only child may give it a vulnerability to disease from which the later additions to the family are free. The first child is an event, the others only incidents, and they are treated accordingly. Parental immaturity is obviously more marked in the production of the heir than of the rest. This may help to show that the first-born, at any rate, does not labour under all the advantages that tradition and law have assigned to him. Let those of us who are younger sons take heart. Our day is coming.

Sex and Smell.

WE all know in a vague sort of way that the senses of sex and smell are related. The bare fact is realised in any work of physiology, but no more. What the connection is we do not know. Kraft-Ebing in his masterly and unpleasant work, *Psychopathia Sexualis*, recognises this very definitely, and gives detailed examples of the incidence of the obvious connection, but beyond this we are in the dark. The genital capricious secretions are coupled in physiological works in olfactory parallel with cheese, an article of diet taboo to the adolescent in France on the plea that it "gives one ideas." Koblanck and Roeder, in Germany, have removed the olfactory organs in immature female animals. When the severity of the operation did not disturb the course of the experiment it was found that turbinate loss arrested in a marked degree the development of ovaries, uterus and vagina, especially the horns of the uterus. Sexual desire was also diminished. These are additions to well-known facts, but we must still wait for the mechanism of the relation to be established. Work on this class of observation is not only likely to be of practical value in educative psychology but it may establish some very interesting details of our racial history.

(a) *Journal of Cutaneous Diseases*, November, 1911.

Trading Laboratories.

UP to quite recently it was assumed that clinical pathology was a branch of medicine, and that the work of the clinical pathologist was part of the profession of medicine. The various clinical laboratories were managed and the reports given by medical men. That this is the only safe course we have not the slightest doubt. It is with considerable alarm, therefore, that we observe that certain manufacturing chemists, and other trading firms, are opening what are described as "research laboratories" for the purpose of examining pathological specimens for medical practitioners, and, in at least one instance, for pharmacists. In some cases these laboratories are advertised as being under the charge of medical men, whose names are given. It is a question, by the way, whether such gentlemen are not guilty of unprofessional conduct. In other cases no guarantee of any sort is given, and we are left to guess at the qualifications of those who make the examinations. Judging from the exiguity of the fees asked—in one case 1s. for report on a diphtheria swab—we are safe in assuming that competent medical men are not employed. It must be borne in mind that a report on a pathological specimen is not a statement of fact, but of opinion, and its only value depends on the skill, knowledge and experience of him who gives the opinion. Viewed in this light the fee of one shilling quoted above is probably exorbitant. The whole subject of clinical laboratories is one that deserves the earnest attention of the profession.

ELSEWHERE in our columns (p. 551) will be found a special report of the Council meeting of the Royal College of Surgeons of England, held on November 14th. Notice was given of three resolutions to be moved at the annual meeting of Fellows and Members on the 21st instant, one endorsing the action of the College with regard to the Insurance Act; the second claiming the right of members to direct representation on the Council; and the third regretting that a special joint meeting had not been called to consider the Act. An important letter was reported by the President, Sir Rickman J. Godlee, addressed by him to the Insurance Commissioners with regard to the position of resident medical officers under the Insurance Act.

PERSONAL.

H. M. THE KING has approved of the award, in the gift of the Sovereign and recommended by the President and Council of the Royal Society, of a Royal Medal to Professor Grafton Elliot Smith, F.R.S., for his researches on the comparative anatomy of the brain.

DR. W. LLEW. DAVIES, of Abernart, has been elected Mayor of Llanidloes, Montgomeryshire.

DR. A. E. BOYCOTT, M.D., Ch.B.Oxon., has been appointed to the Chair of Pathology in the University of Manchester.

DR. MABEL E. GATES, M.D., B.S.Lond., has been appointed a member of the honorary staff of the Exeter Dispensary.

DR. J. W. CROPPER read an interesting paper last week before the Royal Society on "The Development of a Parasite of Earthworms."

DR. W. K. WALLS, M.B.Lond., has been appointed Lecturer in Clinical Obstetrics and Gynaecology in the University of Manchester.

MR. C. BANTING, M.D., B.S., F.R.C.S., has been appointed Assistant to the Ear and Throat Department at University College Hospital.

DR. WILLIAM DICKSON, D.P.H., Assistant Medical Officer for the County of Fife, has been appointed Tuberculosis Officer for the same county.

DR. EDWARD WOAKES, M.D., laryngologist, who died on September 30th, aged 75, left estate valued at £31,157 gross, with net personalty £25,874.

SIR DONALD MACALISTER, K.C.B., M.D., will preside at the forthcoming Session of the General Medical Council on Tuesday, November 26th, at 2 p.m.

DR. A. F. BERNARD SHAW, M.B.Dub., D.P.H., has been appointed Assistant Medical Officer of Health and Assistant School Medical Officer to the City and Port of Cardiff.

DR. FREDERICK R. WALTERS, of Farnham, and Dr. F. W. Wandley Griffin, of Fulham, have been appointed chief tuberculosis officers to the Surrey County Council.

DR. GEORGE CALDERWOOD, who has been Medical Officer of Health for the Egremont Urban District Council for nearly thirty years, has announced his intention of resigning that post at the end of the current year.

MR. WILLIAM THORBURN, F.R.C.S., has been appointed Medical Referee under the Workmen's Compensation Act, 1906, for County Court Circuit No. 5, and to be attached more particularly to Oldham County Court.

DR. POLLARD, Medical Officer of the Blackburn Union, was the recipient the other day of a handsome gift of plate from the staff of the workhouse as a token of the high esteem in which he has been held during his service of over twenty-four years as medical officer.

LIEUT.-COLONEL W. W. O. BEVERIDGE, D.S.O., R.A.M.C., has been selected for appointment as Professor of Military Hygiene at the Royal Army Medical College, Millbank, S.W., in succession to Brevet-Colonel C. H. Melville, whose tenure of the appointment has expired.

THE testimonial of the Royal Humane Society has been presented to Dr. Cornelius C. Hickey for saving the life of a boy who was in danger of drowning near Kilkee last July. Dr. Hickey had to plunge into the sea fully dressed and swim a considerable distance before getting the boy safe ashore.

DR. G. F. BUCHAN, Medical Officer of Health for Heston and Isleworth, was the recipient the other day of a presentation from the members of the district Local Government Officers' Association upon his resigning his post to take up a similar office under the Willesden Urban District Council.

THE President (Sir Francis Champneys, Bart., M.D.) and the Council and Fellows of the Royal Society of Medicine will be at home to members of the profession at the new house of the society, 1, Wimpole Street, W., on November 27th, 28th, 29th, and 30th, at 8.30 p.m. There will be music and epidiascope and cinematograph demonstrations, and smoking will be allowed.

WE are informed that the Carmichael Prize for the best essay on "The State of the Medical Profession in Great Britain and Ireland" has been awarded by the Council of the Royal College of Surgeons of Ireland to Mr. H. Nelson Hardy, F.R.C.S.Edin., of London.

ORIGINAL PAPERS.

THE NEUROLOGY OF THE VISUAL SYSTEM.

A Short series of Original Papers.

By HARRY CAMPBELL, M.D., F.R.C.P.,

Physician to the West End Hospital for Diseases of the Nervous System.

PAPER I.

THE visual system has to be considered under two aspects—the psychic and the motor. The former embraces those nervous processes which, beginning in the retina and ending in the cortex, issue in psychic visual phenomena; the latter embraces all the muscular activities pertaining to vision, those, namely, involving the intrinsic, the extrinsic and the protective muscles of the globes.

THE SENSORY VISUAL SYSTEM.

Anatomical Résumé.—The retina consists of three layers of neurons: (a) rods and cones, (b) bipolar cells, and (c) cells whose fine non-medullated axons constitute the optic nerve fibres. (Fig. 1.)

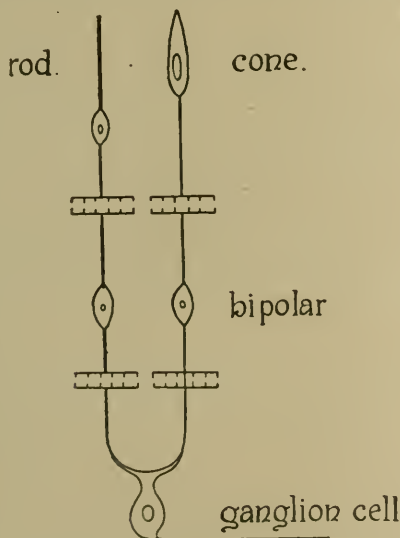

FIG. 1.—Diagram of retina representing the three chief layers of cells. The nerve-impulses started by the impact of light originate in the rod and cone layer. (The cones contract under the influence of light.) The bipolar cells are by most thought to be the analogues of the periphery sensory neurons (photo neurons).

It is estimated that each optic nerve contains nearly a million fibres—*i.e.*, more than the total number of afferent fibres entering one side of the spinal cord. It is the fineness of the optic fibres (due to the tenuity of their axis-cylinders and their lack of any medullary sheath) which renders this large number possible.

The meninges of the brain are continued on to the optic nerves, the sub-dural and sub-arachnoid spaces of the brain being continuous with corresponding spaces around these nerves. (Fig. 2.) The following description of the course of the visuo-sensory tract will be facilitated by a study of Figures 3, 4, 5, 6 and 7.

The fibres from the nasal half of each retina, and those from the macular region (which form a separate set) decussate in the optic chiasma. The macular fibres appear to maintain a central position, alike in the optic nerves, the chiasma, and the optic tracts.

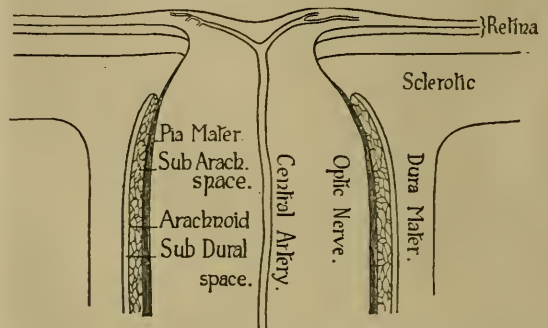

FIG. 2.—Diagram showing the meningeal investments of the optic nerve. These are the same as, and indeed a direct continuation of, those of the brain. Hence the sub-dural and sub-arachnoid spaces of the brain are continued around the optic nerve up to its entrance into the sclerotic ring.

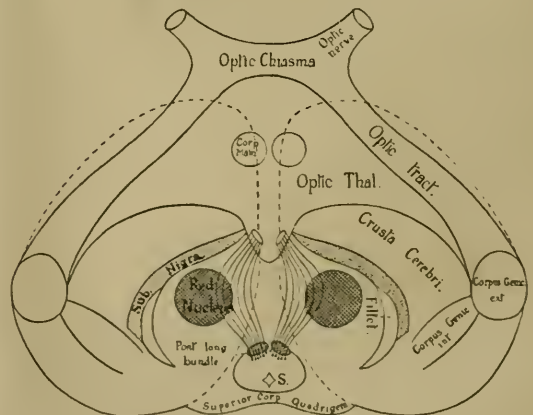

FIG. 3.—This diagram serves as a key to the central part of Fig. 4. It represents a horizontal section, taken through the uppermost part of the brain-stem. [The anterior portions of the optic thalamus lies higher, and the anterior portions of the optic tracts and the chiasma lie lower, than as here represented.] S = aqueduct of Sylvius; anterior to this the roots of the third nerves can be seen arising from their nuclei and passing forwards—many of them traversing the corresponding red nucleus—to issue between the two crura at the base of the brain.

From the chiasma the optic fibres pass into the optic tracts, terminating mostly in the corresponding external geniculate body, though a small number end in the corresponding pulvinar (Degeneration of the pulvinar alone does not

cause hemianopia.) From these centres spring a further series of visual neurons, the axons of which pass through the retro-lenticular part of the internal capsule and the "optic radiations" to the visual cortex. The cortical termination of the pulvinar fibres is not known. The external geniculate fibres terminate as follows: Those pertaining to the macular area of each retina appear to have extensive relations with the visual cortex of both hemispheres, passing mainly to the region

of the angular gyrus (*i.e.*, the convolution bordering the posterior extremity of the superior temporal sulcus), while the non-macular fibres pass to the hemiopic region bounding the calcarine fissure, which separates the cuneus above from the lingual lobe below.

FIG. 4.—Horizontal Section through brain (schematic) showing the visuo-sensory tract. The optic nerves and globes are represented as seen through a transparent brain. Fig. 3 gives the key to the central part of this figure. C=Caudate nucleus, L the lenticular nucleus. The dotted tract on the left starts in the left half of each retina, and terminates in the left hemiopic centre in the posterior part of the brain. The retinal fibres, after traversing the optic tract, are seen to terminate in the corpus geniculatum externum and the pulvinar. Here a further series of neurons originate, their axons passing through the retro-lenticular portion of the internal capsule and the optic radiations.

FIG. 6.—This figure shows a retinal visual fibre coursing along the optic nerve and optic tract, and terminating in the corpus geniculatum externum and the pulvinar. Thence a fresh series of neurons are seen passing backwards to terminate in the peri-calcarine hemiopic area (area striata). The junction of the two series is not clearly shown.

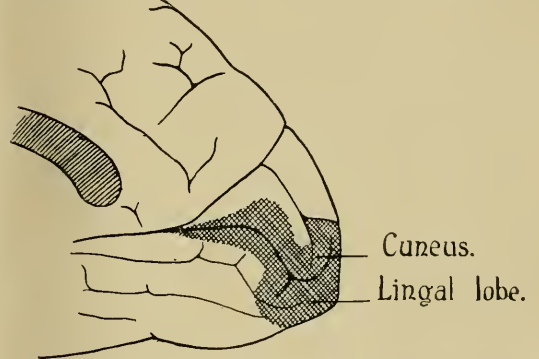

FIG. 7.—Inner aspect of posterior portion of right hemisphere showing the "visuo-sensory area" about the calcarine fissure. It occupies the sides and extends into the depth of the fissure. Anteriorly it occupies the lower lip only.

The hemiopic peri-calcarine area receives fibres belonging to the corresponding lateral half of each retina. Those belonging to the upper half of the corresponding lateral half of the retina pass to the cuneate lobe above the calcarine fissure; those pertaining to the lower half of the corresponding lateral half of the retina pass to the lingual gyrus below the calcarine fissure.

The peri-calcarine hemiopic area can be distinguished from the rest of the cortex by the presence of the well-marked white line of Gennari (=thick granular layer containing a dense plexus of medullated fibres), which is the analogue of the outer line of Baillarger in other parts of the cortex.

This area striata, of which the most characteristic microscopic elements are large stellate pyramids (in the fourth layer), is confined to the sides of the calcarine fissure which it bounds everywhere, except anteriorly, being there limited to the lower lip. Bolton terms the striated hemiopic area the visuo-sensory area, and the circumjacent visual area in the occipital cortex

FIG. 5.—This diagram serves as a key for the central part of Fig. 6. It shows a visual fibre in the optic tract sending a terminal twig to the corpus geniculatum externum and to the pulvinar.

(devoid alike of the line of Gennari and of stellate pyramids) he terms the visuo-psychic area. It would be more accurate to distinguish the two as the primary and secondary visuo-cortical areas, since the term "psychic" is as applicable to the one as to the other.

The hemiopic centres of the two sides are united by means of large medullated fibres which pass through the posterior part (splenium) of the corpus callosum. They occupy the inner side of the optic radiations.

As to its philogenesis, the visual cortex is first met with in the higher fishes, in which fibres can be traced from the corpus geniculatum externum to the posterior part of the cerebrum. In those fishes which have no cortex cerebri, the optic lobes (which correspond to the superior colliculi) represent the highest visual centres. In the monkeys the posterior visual part of the brain is cut off from the rest by the parieto-occipital fissure (Affenspalte) and forms a distinct occipital lobe. In the anthropoid apes and in the lower races of man much of the visual area is seen on the external cerebral surface. In the higher races, most of it is pushed round to the mesial surface.

Besides the fine visual fibres in the optic nerves, chiasma, and tracts, other and thicker fibres are met with. These subserve the light reflex of the iris, and therefore do not come in for consideration here. They behave, as regards decussation in the chiasma, like the visual fibres, terminating, however, not in the pulvinars and external geniculate bodies, but in the superior colliculi, or, as some think, in the third nerve nuclei.

The optic nerves, chiasma, and tracts also contain efferent fibres, the function of which is doubtful.

Mention should here be made of Gudden's Commissure. This consists of fibres uniting the two external geniculate bodies through the optic tracts (by their mesial roots) and the posterior part of the optic chiasma.

The decussation of the optic nerve fibres from the standpoint of comparative anatomy.—The behaviour of the optic fibres, as regards decussation in the chiasma, has a significance on which comparative anatomy sheds some light. In fishes and birds all the fibres of the optic nerves decussate, and in them destruction of the posterior part of one cerebral hemisphere causes blindness of the opposite eye. In fishes these nerves cross separately; in birds they unite, at their crossing, into a chiasma. In both classes the eyes are placed at the sides of the head, with the results that: (a) Each eye images objects on the corresponding side of the sagittal plane only, the two visual fields meeting at this plane (vision is, *i.e.*, periscopic); hence, one side of the brain perceives objects on the opposite side of the sagittal plane only. (b) Each visual field extends considerably backwards (vision is, *i.e.*, panoramic).

As the animal scale is ascended, the eyes gradually shift forwards and two effects follow: (a) The visual field of each eye comes to extend beyond the sagittal plane, causing an overlapping of the two fields, so that objects falling within the overlapping portions are seen by both eyes; *i.e.*, vision is in respect of them binocular. The more forward the eyes come to be situated, the wider does the range of binocular vision become, and it increases with every increment in the power of convergence. (b) With the increase in binocular

vision there is a corresponding diminution in panoramic vision.

Observe that the overlapping portions of the two fields are seen by some part (less or greater according to the degree of overlapping) of the temporal half of each retina. This "seeing" part of the temporal retina images objects on the opposite side of the sagittal plane. Observe, too, that the corresponding fibres (which thus subserve vision of the opposite side) do not decussate but pass direct to the corresponding hemisphere, which, in consequence (as in fishes and birds) also perceives objects on the opposite side. Now it is found that as the vertebrate scale is ascended and the binocular range increases, more and more of the temporal fibres fail to decussate, passing instead direct to the corresponding cerebral hemisphere, until, finally, in the anthropoid apes and man (whose eyes are not only placed in the front of the head, but which also admit of extreme convergence), all the temporal fibres are direct. The effect of this arrangement is that in binocular, as well as in periscopic animals, each hemisphere perceives objects on the opposite side of the sagittal plane.

Carnivorous birds (such as owls and hawks), with eyes looking forward, are an exception to this rule. In them, as in all birds, optic decussation is complete.

The object of binocular vision is to obtain stereoscopic ("solid") vision. This, however, is not achieved until the axes of the two eyes can be converged upon an object, and thus cause it to be imaged upon each macular region, where vision is most acute. Each increase in the power of convergence marks an advance towards perfect stereoscopic vision, for the nearer an object can be "fixed" with both eyes, the greater is the unlikeness between the images belonging to the two eyes, and the greater, therefore, the stereoscopic effect.
